Upper gastrointestinal tract mucosa is prone to injury. Drugs may disturb gastric mucosa protective mechanisms and cause damage. Injury by NSAIDs is a well described complication. Nifedipine, a widely used drug, was not described before as having a potential to damage gastrointestinal mucosa. We describe here, two patients, who developed esophageal and gastric mucosal damage, probably related to Nifedipine ingestion.

Keywords: Esophagitis, Gastric ulcer, Nifedipine

Injury to the upper gastrointestinal tract due to drugs is not uncommon [1–4]. Gastritis caused by NSAIDs is a well described and feared complication [5–12]. Nifedipine was not recognized before as being potentially harmful to the stomach and esophagus. We present here two patients who suffered severe damage, probably due to the ingestion of Nifedipine.

CASE NO. 1

A 62 year old male was admitted to the hospital after vomiting a large amount of blood. The man had hypertension and was taking propranolol, nifedipine and enalapril maleate regularly.

Upon admission he was pale, his blood pressure was 140/70 and his pulse rate was 80/min. Emergency gastroscopy revealed a deep fundic ulcer in which a pill of nifedipine was firmly embedded (Fig. 1). The pill was removed and the patient was treated with cimetidine and recovered.

CASE NO. 2

A 67 year old man presented with dysphagia for solid food. The man had diabetes mellitus and hypertension and was treated with glibenclamide, enalapril maleate and nifedipine. Gastroscopy revealed severe damage to mid-esophagus (Fig. 2). Biopsies for Candida albicans, Herpes virus, and

tuberculosis were negative. He had extensive work-up for various inflammatory and infectious diseases, motility studies, pH 24 h monitoring and small bowel X-ray series. All tests were normal.

The patient did not respond neither to omeprazole, sucralfate nor to acyclovir treatment and needed repeated esophageal dilatations. At that time nifedipine was stopped. The patient gradually improved and the lesion disappeared (Fig. 3).

**DISCUSSION**

Iatrogenic damage to the upper gastrointestinal tract is a well feared problem. The damage caused by NSAIDs is a world-wide problem and the wide use of aspirin adds to it. Corrosive damage to the
upper gastrointestinal tract may cause pain, bleeding, and endanger the life of the patient.

The possible side effect of nifedipine causing severe mucosal damage, was not reported before. The harmful effect on esophageal mucosa was noted by others but not reported. In a single case report from Japan [13] severe esophagitis was reported in a woman, creating esophagogastric fistula. The authors noted that the woman began taking nifedipine one week earlier, but did not make the link. Due to the very common use of nifedipine, we suggest that caution should be taken whenever gastrointestinal symptoms appear.
