The synthesis of novel nickel(II) complexes with new ligand derived from hydrazone of isoniazid has been reported. The complexes have general compositions \([\text{Ni}(L)_2\text{X}_2]\) or \([\text{Ni}(L)_3\text{(ClO}_4)_2]\), where \(L = \text{N-isonicotinamido-furfuraldimine (INH-FFL)}\) and \(X = \text{Cl}^−\) or \(\text{NCS}^−\). The ligand hydrazone behaves as neutral bidentate (N and O donor) through the carbonyl oxygen and azomethine nitrogen. On the basis of elemental analysis, molecular weight determinations, magnetic susceptibility/moment, thermogravimetric, electrochemical, and spectroscopic studies, the new complexes have been characterized with octahedral geometry. The antibacterial and antifungal studies of the present complexes show that they are moderate antibacterial and antifungal agents.

1. Introduction

The synthesis of transition metal complexes with Schiff bases of nitrogen and oxygen donor has stimulated interest due to their vast variety of biological activities ranging from pharmacological, antitumour, fungicide, bactericide, anti-inflammatory, and antiviral activities [1, 2]. We have recently published some lanthanide(III) complexes of semicarbazones [3] and oxovanadium(IV) [4, 5], platinum(II) [6], cobalt(II), and nickel(II) [2, 7] complexes of thiosemicarbazones derived from 4-aminoantipyrine. The antibacterial and antifungal properties of the thiosemicarbazone ligands and their cobalt(II) [2, 7], nickel(II) [7], and oxovanadium(IV) [5] complexes have also been examined. In continuation of our work on hydrazones of isoniazid (a drug of proven therapeutical importance [8]) complexes of metal ions [9], the present work describes the synthesis, magneto-spectral, electrochemical, thermal, and biological studies of a novel series of Ni(II) complexes of N-isonicotinamido-furfuraldimine (INH-FFL) (Figure 1).

2. Experimental

The nickel(II) salt, NiCl₂·6H₂O, was obtained from BDH and used as received. Ni(NCS)₂ and Ni(ClO₄)₂ were prepared by methods reported elsewhere [7]. The hydrazone of isoniazid viz. INH-FFL was synthesized by following a general method reported by us [9] (yield ca. 80%). A general method was used for the synthesis of the nickel(II) complexes [7]. A hot ethanolic solution of the corresponding nickel(II) salt was mixed with a hot ethanolic solution of the hydrazone ligand in molar ratio 1:2, and 1:3 for \([\text{Ni}(L)_2\text{X}_2]\) and \([\text{Ni}(L)_3\text{(ClO}_4)_2]\) complexes, respectively. The reaction mixture was refluxed on a water bath for ~2 hours. On cooling the reaction mixture at room temperature, the colored complexes precipitated out in each case. The complexes were filtered out, recrystallized, washed with ethanol, and dried over P₂O₅ under vacuum. The molecular weight of the complexes was determined cryoscopically using Beckmann thermometer. The nickel contents of the complexes were determined complexomet-
The reaction of nickel(II) salts with INH-FFL resulted in the formation of \([\text{NiX}_2(\text{L})_n]\), where \(X = \text{Cl}^-, \text{NCS}^-, \text{NO}_2^-\), and \([\text{Ni}(\text{L})_n\text{X}_2]\), while \(X = \text{ClO}_4^-, n = 2\), and \([\text{Ni}(\text{L})_n\text{X}_2]\), while \(X = \text{ClO}_4^-, n = 3\). The analytical data, molar conductance in nitrobenzene, and molecular weights of the complexes are presented in Table 1. The complexes were quite stable and could be stored for several weeks without any appreciable change but decomposed on heating beyond 250°C. The paramagnetism observed for the present complexes ranges from 3.1–3.2 BM (Table 1) and is consistent with the octahedral stereochemistry [7].

The infrared frequencies in the present ligand associated with amide group (carbonyl-oxygen), azomethine-nitrogen (C=N), and hetrocyclic nitrogen are expected to be influenced on complex formation with nickel(II). Generally, amides show two absorption bands: (i) the carbonyl absorption band near 1640 cm\(^{-1}\) and (ii) strong band in the 1600-1500 cm\(^{-1}\) region (amide-II band). The amide-I band in INH-derivatives, however, appeared at 1655 cm\(^{-1}\) [11]. In the infrared spectra of the complexes, a considerable negative shift in \(\nu(\text{C}=\text{O})\) was observed indicating a decrease in the stretching force constant of (C=O) as a consequence of coordination through the carbonyl oxygen atom of the ligand. Another important band occurs at 1585 cm\(^{-1}\) range is attributed to \(\nu(\text{C}=\text{N})\) (azomethine) mode [12]. In spectra of all the complexes, this band is shifted to lower wave number and appears in 1545-1535 cm\(^{-1}\) region indicating the involvement of N-atom of the azomethine group in coordination [12]. The overall infrared spectral evidence suggests that the present ligand acts as bidentate ligand and coordinates through amide oxygen and azomethine nitrogen atoms forming a five-membered chelate ring. The three fundamental absorptions in [Ni(NCS)\(_2\)(L)\(_2\)] complex, that is, C-N stretching (\(\nu_1\)), C-S stretching (\(\nu_2\)), and N-C-S bending (\(\nu_3\)) identified at 2040-2035, 845-830, and 470-465 cm\(^{-1}\) region are associated with the terminal N-bonded isothiocyanate ions [7]. In the perchlorato complex, the presence of the \(\nu_3(1100-1090\text{ cm}^{-1})\) and \(\nu_4(625-620\text{ cm}^{-1})\) bands indicates that the \(T_d\) symmetry of ClO\(_4^-\) is maintained in the complex. It suggests the presence of ClO\(_4^-\) outside the coordination sphere [13].

The electronic spectra of the octahedral nickel(II) complexes exhibit spectra showing three spin-allowed transitions in 7000–11000 cm\(^{-1}\) (\(\nu_1\)), 15000–19000 cm\(^{-1}\) (\(\nu_2\)), and 25000–29000 cm\(^{-1}\) (\(\nu_3\)) regions [2, 7]. In the present complexes, the electronic spectra were very similar to each other and consist of bands in 8200–10930 \(\{\nu_1, \nu_2A_g(F) \rightarrow 3T_{2g}(F)\}\), 17540–17700 \(\{\nu_2,4T_{1g}(F) \rightarrow 4A_g(F)\}\), and 26950–27500 cm\(^{-1}\) \(\{\nu_4,4T_{1g}(F) \rightarrow 4T_{2g}(P)\}\) regions, which clearly indicated the octahedral stereochemistry of the complexes.

The thermogravimetric results of representative complexes clearly suggested the absence of any water molecule in the complexes. During 160–265°C temperature range, the weight loss corresponds to 37.21–39.34% indicates the loss of one molecule of INH-FFL, while second ligand molecule evaporated at ~400°C. Finally, at ~600°C, NiO formation takes place according to the following general equation:

\[
\begin{align*}
[\text{Ni(INH-FFL)}_2\text{Cl}_2] & \overset{175-265^\circ\text{C}}{\longrightarrow} [\text{Ni(INH-FFL)}\text{Cl}_2] \\
[\text{NiCl}_2] & \overset{325-400^\circ\text{C}}{\longrightarrow} \text{NiO} \\
[\text{Ni(FFL)}_2\text{Cl}] & \overset{515-600^\circ\text{C}}{\longrightarrow} \text{NiO}
\end{align*}
\]

The antibacterial activities of the nickel(II) complexes and standard drugs (ampicillin and tetracycline) were screened using reported methods [2]. The antibacterial and antifungal activities of the complexes against two fungi (Aspergillus niger and Staphylococcus aureus), and gram negative bacteria, Escherichia coli and Salmonella typhi, which show that the nickel(II) complexes of INH-FFL have moderate antibacterial activity against these bacteria (Table 2). The screened antifungal activities of the complexes against two fungi (Aspergillus niger and Candida albicans) show that they are less active compared to salicylic acid and appear to be moderate antifungal agents (Table 2). The antibacterial and antifungal activities of the present complexes were also compared with the activity results of some other nickel(II) complexes having different ligands (Table 2) [14–17]. It was found that the present complexes are less potent bactericides with respect to few reported nickel(II) complexes [14, 15], while some other complexes have almost comparable [16, 17] or less [17] antibacterial and antifungal activities. However, the experimental conditions for complexes reported in literature are different [14–17].

The overall experimental evidences thus show that the studied nickel(II) complexes, [Ni(L)\(_2\)X\(_2\)] and...
