We propose two algorithms of two-level methods for resolving the nonlinearity in the stabilized finite volume approximation of the Navier-Stokes equations describing the equilibrium flow of a viscous, incompressible fluid. A macroelement condition is introduced for constructing the local stabilized finite volume element formulation. Moreover the two-level methods consist of solving a small nonlinear system on the coarse mesh and then solving a linear system on the fine mesh. The error analysis shows that the two-level stabilized finite volume element method provides an approximate solution with the convergence rate of the same order as the usual stabilized finite volume element solution solving the Navier-Stokes equations on a fine mesh for a related choice of mesh widths.

1. Introduction

We consider a two-level method for the resolution of the nonlinear system arising from finite volume discretizations of the equilibrium, incompressible Navier-Stokes equations:

\[-\nu \Delta u + (u \cdot \nabla)u + \nabla p = f \quad \text{in} \ \Omega, \quad (1.1)\]
\[\nabla \cdot u = 0 \quad \text{in} \ \Omega, \quad (1.2)\]
\[u = 0 \quad \text{in} \ \partial \Omega, \quad (1.3)\]

where \( u = (u_1(x), u_2(x)) \) is the velocity vector, \( p = p(x) \) is the pressure, \( f = f(x) \) is the body force, \( \nu > 0 \) is the viscosity of the fluid, and \( \Omega \subset \mathbb{R}^2 \), the flow domain, is assumed to
be bounded, to have a Lipschitz-continuous boundary \( \partial \Omega \), and to satisfy a further condition stated in (H1).

Finite volume method is an important numerical tool for solving partial differential equations. It has been widely used in several engineering fields, such as fluid mechanics, heat and mass transfer, and petroleum engineering. The method can be formulated in the finite difference framework or in the Petrov-Galerkin framework. Usually, the former one is called finite volume method \([1, 2]\), MAC (marker and cell) method \([3]\), or cell-centered method \([4]\), and the latter one is called finite volume element method (FVE) \([5–7]\), covolume method \([8]\), or vertex-centered method \([9, 10]\). We refer to the monographs \([11, 12]\) for general presentations of these methods. The most important property of FVE is that it can preserve the conservation laws (mass, momentum, and heat flux) on each control volume. This important property, combined with adequate accuracy and ease of implementation, has attracted more people to do research in this field.

On the other hand, the two-level finite element strategy based on two finite element spaces on one coarse and one fine mesh has been widely studied for steady semilinear elliptic equations \([13, 14]\) and the Navier-Stokes equations \([15–22]\). For the finite volume element method, Bi and Ginting \([23]\) have studied two-grid finite volume element method for linear and nonlinear elliptic problems; Chen et al. \([24]\) have applied two-grid methods for solving a two-dimensional nonlinear parabolic equation using finite volume element method. Chen and Liu \([25]\) have also studied this method for semilinear parabolic problems. However, to the best of our knowledge, there is no two-level finite volume convergence analysis for the Navier-Stokes equations in the literature.

In this paper we aim to combine FVE method based on \( P_1 - P_0 \) macroelement with two-level strategy to solve the two-dimensional Navier-Stokes (1.1)–(1.3). The heart of the analysis is the use of a transfer operator to connect finite volume and finite element estimations which will lead to more difficult term to estimate. We choose the two-grid spaces as two conforming finite element spaces \( X_H \) and \( X_h \) on one coarse grid with mesh size \( H \) and one fine grid with mesh size \( h \ll H \). We propose two algorithms of two-level method for resolving the nonlinearity in the stabilized finite volume approximation of the problem (1.1)–(1.3): the simple and Newton algorithms. First we prove that the simple two-level stabilized finite volume solution \((u^h, p^h)\) is the following error estimate:

\[
\|u - u^h\|_1 + \|p - p^h\|_0 \leq C \left( h + H^2 \right).
\] (1.4)

Second we prove that the Newton two-level stabilized finite volume solution \((u^h, p^h)\) is the following error estimate:

\[
\|u - u^h\|_1 + \|p - p^h\|_0 \leq C \left( h + H^3 \log h \right)^{1/2},
\] (1.5)

where \( C \) denotes some generic constant which may stand for different values at its different occurrences.

Hence, the two-level algorithms achieve asymptotically optimal approximation as long as the mesh sizes satisfy \( h = O(H^2) \) for the simple two-level stabilized finite volume solution and \( h = O(H^3 \log h) \) for the Newton two-level stabilized finite volume solution. As a result, solving the nonlinear Navier-Stokes equations will not be much more difficult than solving one single linearized equation.
The rest of this paper is organized as follows. In the next section, we introduce some notations and construct a FVE scheme. In Section 3 we recall some preliminary estimates of the stabilized finite volume approximations. Finally the two-level FVE algorithms and the improved error estimates are presented and established in Section 4.

2. Finite Volume Scheme

2.1. Notations

We will use $\| \cdot \|_m$ and $| \cdot |_m$ to denote the norm and seminorm of the Sobolev space $(H^m(\Omega))^d$, $d = 1, 2$. Let $H_0^1(\Omega)$ be the standard Sobolev subspace of $H^1(\Omega)$ of functions vanishing on $\partial \Omega$. We introduce the following notations:

$$X = (H_0^1(\Omega))^2, \quad Y = L_0^2(\Omega) = \left\{ q : q \in L^2(\Omega), \int_\Omega q = 0 \right\}.$$  \hspace{1cm} (2.1)

The scalar product and norm in $Y$ are denoted by the usual $L^2(\Omega)$ inner product $(\cdot, \cdot)$ and $\| \cdot \|_0$, respectively. As mentioned above, we need a further assumption on $\Omega$.

H1

Assume that $\Omega$ is regular so that the unique solution $(v, q) \in X \times Y$ of the steady Stokes problem

$$-\Delta v + \nabla q = g, \quad \nabla \cdot v = 0; \quad v|_{\partial \Omega} = 0$$  \hspace{1cm} (2.2)

for a prescribed $g \in (L^2(\Omega))^2$ exists and satisfies

$$\|v\|_2 + \|q\|_1 \leq C\|g\|_0,$$  \hspace{1cm} (2.3)

where $C > 0$ is a constant depending on $\Omega$.

The weak formulation of the problem (1.1)–(1.3) is to find $(u, p) \in X \times Y$ such that

$$a(u, v) - d(v, p) + b(u, u, v) = (f, v), \quad \forall v \in X,$$

$$d(u, q) = 0, \quad \forall q \in Y,$$  \hspace{1cm} (2.4)
where the bilinear forms $a(\cdot, \cdot)$, $d(\cdot, \cdot)$ and the trilinear form $b(\cdot, \cdot, \cdot)$ are given by

$$a(u, v) = \nu(\nabla u, \nabla v) = \nu \int_{\Omega} \nabla u : \nabla v \, dx, \quad \forall u, v \in X,$$

$$d(v, q) = (\nabla \cdot v, q) = \int_{\Omega} q \nabla \cdot v \, dx, \quad \forall u, q \in X \times Y,$$

$$b(u, w, v) = ((u \cdot \nabla w), v) + \frac{1}{2}((\nabla \cdot u)w, v)$$

$$= \frac{1}{2}(u \cdot \nabla w), v) - \frac{1}{2}((u \cdot \nabla w), w) \quad \forall u, v, w \in X. \quad (2.5)$$

Introducing the generalized bilinear form on $(X \times Y)^2$ by

$$B((u, p); (v, q)) = a(u, v) - d(v, p) + d(u, q), \quad (2.6)$$

we can rewrite (2.4) in a compact form: find $(u, p) \in X \times Y$ such that

$$B((u, p); (v, q)) + b(u, u, v) = (f, v), \quad \forall (v, q) \in X \times Y. \quad (2.7)$$

Let $\mathcal{T}_h$ be a quasi-uniform triangulation of $\Omega$ with $h = \max h_K$, where $h_K$ is the diameter of the triangle $K \in \mathcal{T}_h$. We assume that the partition $\mathcal{T}_h$ has been obtained from a macrotriangular partition $\Lambda_h$ by joining the sides of each element of $\Lambda_h$. Every element $K \in \mathcal{T}_h$ must lie in exactly one macroelement $\mathcal{K}$, which implies that macroelements do not overlap. For each $\mathcal{K}$, the set of interelement edges which are strictly in the interior of $\mathcal{K}$ will be denoted by $\Gamma_{\mathcal{K}}$, and the length of an edge $e \in \Gamma_{\mathcal{K}}$ is denoted by $h_e$.

Based on this triangulation, let $X_h$ be the standard conforming finite element subspace of piecewise linear velocity,

$$X_h = \{ v \in C(\Omega) \cap X : v|_{K} \text{ is linear}, \forall K \in \mathcal{T}_h; v|_{\partial \Omega} = 0 \}, \quad (2.8)$$

and let $Y_h$ be the piecewise constant pressure subspace

$$Y_h = \{ q \in Y : q|_K \text{ is constant}, \forall K \in \mathcal{T}_h \}. \quad (2.9)$$

It is well known that the standard $P_1 - P_0$ element does not satisfy the inf-sup condition and cannot be applied to problem (1.1)–(1.3) directly. But a locally stabilized method based on the macroelement can be used to yield adequate approximations [6].

In order to describe the FVE method for solving problem (1.1)–(1.3), we will introduce a dual partition $\mathcal{T}_h^\star$ based upon the original partition $\mathcal{T}_h$, whose elements are called control volumes. We construct the control volumes in the same way as in [5, 26]. Let $z_K$ be the barycenter of $K \in \mathcal{T}_h$. We connect $z_K$ with line segments to the midpoints of the edges of $K$, thus partitioning $K$ into three quadrilaterals $K_{xz}$, $z \in Z_h(K)$, where $Z_h(K)$ are the vertices of $K$. Then with each vertex $z \in Z_h = \cup_{K \in \mathcal{T}_h} Z_h(K)$, we associate a control volume $V_z$, which consists of the union of the subregions $K_{xz}$, sharing the vertex $z$. Thus we finally obtain
a group of control volumes covering the domain $\Omega$, which is called the dual partition $T^*_h$ of the triangulation $T_h$. We denote by $Z^0_h$ the set of interior vertices.

We call the partition $T^*_h$ regular or quasi-uniform if there exists a positive constant $C > 0$ such that

$$C^{-1} h^2 \leq \text{meas}(V_z) \leq Ch^2, \quad V_z \in T^*_h.$$  \hfill (2.10)

If the finite element triangulation $T_h$ is quasi-uniform, then the dual partition $T^*_h$ is also quasi-uniform [23].

### 2.2. Construction of the FVE Scheme

We formulate the FVE method for the problem (1.1)–(1.3) as follows: given a $z \in Z^0_h$ and $K \in T_h$, integrating (1.1) over the associated control volume $V_z$ and (1.1) over the element $K$ and applying Green’s formula, we obtain an integral conservation form

$$-\nu \int_{\partial V_z} \nabla u \cdot ds + \int_{\partial V_z} pn \, ds + \int_{V_z} u \cdot \nabla u \, dx = \int_{V_z} f \, dx, \quad \forall z \in Z^0_h, \quad \forall K \in T_h,$$  \hfill (2.11)

$$\int_K \nabla \cdot u \, dx = 0, \quad \forall K \in T_h,$$  \hfill (2.12)

where $n$ denotes the unit outer normal vector to $\partial V_z$ (Figure 1).

Let $I^*_h : X_h \to X^*_h$ be the transfer operator defined by

$$I^*_h v = \sum_{z \in Z^0_h} v(z) \chi_z, \quad \forall v \in X_h,$$  \hfill (2.13)
where

\[
X_h^* = \left\{ v = (v_1, v_2) \in \left( L^2(\Omega) \right)^2 : v_i|_{V_z} \text{ is constant}, i = 1, 2 \ \forall z \in Z^0_h \right\},
\]  
\tag{2.14}

and \( \chi_z \) is the characteristic function of the control volume \( V_z \). The operator \( I_h^* \) satisfies

\[
\| I_h^* v \|_0 \leq C \| v \|_0, \quad \forall v \in X_h.
\]  
\tag{2.15}

Now for an arbitrary \( I_h^* v \), we multiply (2.11) by \( v(z) \) and sum over all \( z \in Z^0_h \) to get

\[
a_h(u, I_h^* v) - d_h(I_h^* v, p) + b_h(u, u, I_h^* v) = (f, I_h^* v), \quad \forall v \in X_h.
\]  
\tag{2.16}

Here \( a_h : X \times X_h \to \mathbb{R} \), \( d_h : X_h \times Y \to \mathbb{R} \), and \( b_h : X \times X \times X_h \to \mathbb{R} \) are defined by

\[
a_h(u, I_h^* v) = -\nu \sum_{z \in Z^0_h} v(z) \int_{\partial V_z} \nabla u \cdot n \, ds,
\]
\[
d_h(I_h^* v, p) = \sum_{z \in Z^0_h} v(z) \int_{\partial V_z} pn \, ds,
\]  
\tag{2.17}

\[
b_h(u, u, I_h^* v) = \sum_{z \in Z^0_h} v(z) \int_{V_z} (u \cdot \nabla) u \, dx.
\]

We also define the trilinear forms \( \tilde{b}(\cdot, \cdot, \cdot) \) and \( \tilde{b}(\cdot, \cdot, \cdot) \) on \( X \times X \times X_h \) by

\[
\tilde{b}(u, v, I_h^* w) = (u \cdot \nabla) v, I_h^* w + \frac{1}{2} \left( (\nabla \cdot u) v, I_h^* w \right),
\]  
\tag{2.18}

\[
\tilde{b}(u, v, w - I_h^* w) = (u \cdot \nabla) v, w - I_h^* w + \frac{1}{2} \left( (\nabla \cdot u) v, w - I_h^* w \right).
\]

To formulate the discrete problem so as to eliminate any such potential difficulties, we rewrite (2.16) as follows:

\[
a_h(u, I_h^* v) - d_h(I_h^* v, p) + \tilde{b}(u, u, I_h^* v) = (f, I_h^* v), \quad \forall v \in X_h.
\]  
\tag{2.19}

We multiply (2.12) by \( q \in Y_h \) and sum over all \( K \in \mathcal{T}_h \): then, we obtain

\[
b(u, q) = 0, \quad \forall q \in Y_h.
\]  
\tag{2.20}
Now we rewrite (2.19) and (2.20) to a variational form similar to finite element problems. The locally stabilized FVE scheme is to find $(u_h, p_h) \in X_h \times Y_h$ such that

$$
a_h(u_h, \Gamma_h^* v_h) - d_h(I_h^* v_h, p_h) + \tilde{b}(u_h, u_h, I_h^* v_h) = (f, \Gamma_h^* v_h), \quad \forall v_h \in X_h, \\
d(u_h, q_h) - \beta c_h(p_h, q_h) = 0, \quad \forall q_h \in Y_h,
$$

where

$$c_h(p, q) = \sum_{e \in \mathcal{E}_k} \sum_{e \in \mathcal{E}_k} I_e \int_e [p]_e [q]_e ds \quad (2.22)$$

is a stabilized form defined on $(H^1(\Omega) + Y_h)^2$, $[\cdot]_e$ is the jump operator across the edge $e$, and $\beta > 0$ is the local stabilization parameter. It is trivial that $c_h(p, q_h) = c_h(p_h, q) = c_h(p, q) = 0$, for all $p, q \in H^1(\Omega)$, for all $p_h, q_h \in Y_h$.

A general framework for analyzing the locally stabilized formulation (2.21) can be developed using the notion of equivalence class of macroelements. As in Stenberg [27] each equivalence class, denoted by $\mathcal{E}_k$, contains macroelements which are topologically equivalent to a reference macroelement $\mathcal{K}$.

Let

$$\overline{B}_h((u_h, p_h); (I_h^* v_h, q_h)) = a_h(u_h, I_h^* v_h) - d_h(I_h^* v_h, p_h) + d(u_h, q_h), \quad (2.23)$$

$$B_h((u_h, p_h); (I_h^* v_h, q_h)) = \overline{B}_h((u_h, p_h); (I_h^* v_h, q_h)) + \beta c_h(p_h, q_h). \quad (2.24)$$

We can rewrite (2.21) in a compact form: find $(u_h, p_h) \in X_h \times Y_h$ such that

$$B_h((u_h, p_h); (I_h^* v_h, q_h)) + \tilde{b}(u_h, u_h, I_h^* v_h) = (f, \Gamma_h^* v_h), \quad \forall (v_h, q_h) \in X_h \times Y_h. \quad (2.25)$$

### 3. Technical Preliminaries

This section considers preliminary estimates which will be very useful in the error estimates of two-level finite volume solution $(u_h^0, p_h^0)$.

The following lemma gives the boundedness of the trilinear form $b(\cdot, \cdot, \cdot)$. 
Lemma 3.1 (see [21]). The following estimates hold:

\[ b(u, w, v) = -b(u, v, w), \]

\[ |b(u, w, v)| \leq \frac{1}{2} C_0 ||u||_0 ||v||_{\Omega}^{1/2} ||u||^{1/2} \left( ||w||_{\Omega}^{1/2} ||v||_{\Omega}^{1/2} + ||w||^{1/2} ||v||^{1/2} \right), \quad \forall u, v, w \in X, \]

\[ |b(u, v, w)| + |b(v, u, w)| + |b(w, u, v)| \leq C_1 ||u||_1 ||v||_1 ||w||_0, \quad \forall u \in X, \quad v \in (H^2(\Omega))^2 \cap X, \quad w \in Y, \]

\[ |b(u, v, w)| \leq C|\log h| ||u||_1 ||v||_1 ||w||_0, \quad \forall u, v, w \in X_h. \]

(3.1)

Here and after \( C_i, i = 1, 2, \) and \( C \) are positive constants depending only on the data \((v, f, \Omega)\).

The existence and uniqueness results of (2.7) can be found in [28, 29].

Theorem 3.2. Assume that \( \nu > 0 \) and \( f \in Y \) satisfy the following uniqueness condition:

\[ 1 - \frac{N_1}{\nu^2} ||f||_{-1} > 0, \]

(3.2)

where

\[ N_1 = \sup_{u,v,w \in X} \frac{b(u, v, w)}{||u||_1 ||v||_1 ||w||_1}. \]

(3.3)

Then the problem (2.7) admits a unique solution \((u, p) \in (H^1_0(\Omega))^2 \cap X, H^1(\Omega) \cap Y)\) such that

\[ ||u||_1 \leq \frac{1}{\nu} ||f||_{-1}, \quad ||u||_2 + ||p||_1 \leq C ||f||_0. \]

(3.4)

In [30] the following lemma was proved, which shows that the finite volume element bilinear forms \( a_h(\cdot, I_h^* \cdot) \) and \( d_h(I_h^* \cdot, \cdot) \) are equal to the finite element ones, respectively.

Lemma 3.3. For any \( u_h, v_h \in X_h \), and \( q_h \in Y_h \), one has

\[ a_h(u_h, I_h^* v_h) = a(u_h, v_h), \]

\[ d_h(I_h^* v_h, q_h) = d(v_h, q_h). \]

(3.5)

The following theorem establishes the weak coercivity of (2.24) [6, 31].

Theorem 3.4. Given a a stabilization parameter \( \beta \geq \beta_0 \), suppose that every macroelement \( \mathcal{K} \in \Lambda_h \) belongs to one of the equivalence classes \( \mathcal{E}_\mathcal{K} \) and that the following macroelement connectivity...
condition is valid: for any two neighboring macroelements $\mathcal{K}_1$ and $\mathcal{K}_2$ with $\mathcal{K}_1 \cap \mathcal{K}_2 \neq \emptyset$, there exists $v \in X_h$ such that

$$\operatorname{supp} v \subset \mathcal{K}_1 \cap \mathcal{K}_2 \int_{\mathcal{K}_1 \cap \mathcal{K}_2} v \cdot nds \neq 0.$$ (3.6)

Then

$$\alpha_1 (|u_h|_1 + \|p_h\|_0) \leq \sup_{(v_h,q_h) \in X_h \times Y_h} \frac{B_h((u,p); (I_h^* v_h, q_h))}{|v_h|_1 + \|q_h\|_0},$$ (3.7)

for all $(u_h, p_h) \in X_h \times Y_h$, and

$$|B_h((u,p); (I_h^* v_h, q_h))| \leq \alpha_2 (|u_h|_1 + \|p_h\|_0) \left( |v_h|_1 + \|q_h\|_0 \right) \quad (v_h,q_h) \in X_h \times Y_h$$ (3.8)

where $\alpha_1, \alpha_2 > 0$ are constants independent of $h$ and $\beta$, $\beta_0$ is some fixed positive constant, and $n$ is the out-normal vector.

Next, we establish the existence and the uniqueness of FVE scheme (2.25), by the fixed-point theorem, in the following.

**Theorem 3.5** (see [6]). Suppose the assumptions of Theorems 3.2 and 3.4 hold, and the body force $f$ satisfies the following uniqueness condition

$$1 - \frac{4N}{\nu^2} \|f\|_{-1} > 0.$$ (3.9)

Then the variation problem (2.25) admits a unique solution $(u_h, p_h) \in (X_h \times Y_h)$ such that

$$|u_h|_1 \leq \frac{1}{\nu} \|f\|_{-1}, \quad \|p_h\|_0 \leq \frac{\alpha_2}{\alpha_1} \|f\|_{-1} + \frac{4\alpha_2 N}{\alpha_1 \nu^2} \|f\|_{-1},$$ (3.10)

where

$$N = \max\{CN_1, N_2\}, \quad N_2 = \sup_{u,v,w \in X} \frac{\bar{b}(u,v,I^* w)}{|u|_1 |v|_1 |w|_1}.$$ (3.11)

For the error estimate, we introduce the Galerkin projection $(R_h, Q_h) : X \times Y \to X_h \times Y_h$ defined by

$$B_h((R_h(v,q), Q_h(v,q)); (I_h^* v_h, q_h)) = \bar{B}_h((v,q); (I_h^* v_h, q_h))$$ (3.12)

for each $(v,q) \in X \times Y$ and all $(v_h,q_h) \in X_h \times Y_h$. We obtain the following results by using the standard Galerkin finite element [6, 17].
Theorem 3.6. Under the assumptions of Theorems 3.2 and 3.4, the projection \( (R_h, Q_h) \) satisfies
\[
|v - R_h(v, q)|_1 + \|q - Q_h(v, q)\|_0 \leq C(|v|_1 + \|q\|_0),
\]
for all \((v, q) \in X \times Y\) and
\[
\|v - R_h(v, q)\|_0 + h(|v - R_h(v, q)|_1 + \|q - Q_h(v, q)\|_0) \leq Ch^2(\|v\|_2 + \|q\|_1),
\]
for all \((v, q) \in (D(A) \cap X) \times (H^1(\Omega) \cap Y)\).

Then the optimal error estimates can be obtained as follows.

Theorem 3.7 (see [6, 32]). Under the assumptions of Theorems 3.2, 3.4, 3.5, and 3.6, the solution \((u_h, p_h)\) of (2.25) satisfies
\[
\|u - u_h\|_0 + h(|u - u_h|_1 + \|p - p_h\|_0) \leq Ch^2.
\]

4. Two-Level FVE Algorithms and Its Error Analysis

In this section, we will present two-level stabilized finite volume element algorithm for (1.1)–(1.3) and derive some optimal bounds for errors. The idea of the two-level method is to reduce the nonlinear problem on a fine mesh into a linear system on a fine mesh by solving a nonlinear problem on a coarse mesh. The basic mechanisms are two quasi-uniform triangulations of \( \Omega \), \( \mathcal{T}_H \), and \( \mathcal{T}_h \), with two different mesh sizes \( H \) and \( h \( (h \ll H) \), and the corresponding solutions spaces \( (X_H, Y_H) \) and \( (X_h, Y_h) \), which satisfy \( (X_H, Y_H) \subset (X_h, Y_h) \) and will be called the coarse and the fine spaces, respectively. Now find \((u^h, p^h)\) as follows.

Algorithm 4.1 (Simple two-level stabilized FVE approximation). We have the following steps:

Step 1. On the coarse mesh \( \mathcal{T}_H \), solve the stabilized Navier-Stokes problem.
Find \((u_H, p_H) \in X_H \times Y_H\) such that, for all \((v_H, q_H) \in X_H \times Y_H\),
\[
B_H((u_H, p_H); (I_H^*v_H, q_H)) + \tilde{b}(u_H, u_H, I_H^*v_H) = (f, I_H^*v_H).
\]

Step 2. On the fine mesh \( \mathcal{T}_h \), solve the stabilized linear Stokes problem.
Find \((u_h^h, p_h^h) \in X_h \times Y_h\) such that, for all \((v_h, q_h) \in X_h \times Y_h\),
\[
B_h((u_h^h, p_h^h); (I_h^*v_h, q_h)) + \tilde{b}(u_h^h, u_h^h, I_h^*v_h) = (f, I_h^*v_h).
\]

Next, we study the convergence of \((u^h, p^h)\) to \((u, p)\) in some norms. For convenience, we set \( e = R_h(u, p) - u^h \) and \( \eta = Q_h(u, p) - p^h \).

Theorem 4.2. Under the assumptions of Theorems 3.2, 3.4, 3.5, and 3.6 for \( H \) and \( h \), the simple two-level stabilized FVE solution \((u^h, p^h)\) satisfies the following error estimates:
\[
\|u - u^h\|_1 + \|p - p^h\|_0 \leq C(h + H^2).
\]
Proof. Subtracting (4.2) from (2.25) and using the Galerkin projection (3.12), it is easy to see that

\[
B_h\left((e, \eta); (I_h^* v_h, q_h)\right) + b(u, u - u_H, v_h) + b(u - u_H, u, v_h) - b(u - u_H, u - u_H, v_h) \\
+ \tilde{b}(u - u_H, u - u_H, v_h) - \tilde{b}(u - u_H, u, v_h - I_h^* v_h) \\
- \tilde{b}(u, u - u_H, v_h - I_h^* v_h) + \tilde{b}(u, u, v_h - I_h^* v_h) = (f, v_h - I_h^* v_h),
\]

(4.4)

for all \((v_h, q_h) \in X_h \times Y_h\). Due to (3.7), Lemma 3.1, (3.15), and (4.4), we have

\[
\alpha_1(|\epsilon|^1 + \|\eta\|_0) \leq \sup_{(v_h, q_h) \in X_h \times Y_h} \frac{B_h((u, p); (I_h^* v_h, q_h))}{|v_h|^1 + \|q_h\|_0} \\
\leq C\|u\|_2\|u - u_H\|_0 + C\|u - u_H\|^2 + Ch\|u\|_2\|u - u_H\|_1 + Ch \\
\leq C\left(H^2 + h\right),
\]

which, along with (3.14), yields

\[
\left|u - u_h^h\right|^1 + \|p - p_h\|^1_0 \leq \left|u - R_h(u, p)\right|^1 + \|p - Q_h(u, p)\|_0 + |\epsilon|^1 + \|\eta\|_0 \\
\leq C\left(h + H^2\right).
\]

(4.6)

Algorithm 4.3 (The Newton two-level stabilized FVE approximation). We have the following steps:

Step 1. On the coarse mesh \(T_H\), solve the stabilized Navier-Stokes problem.
Find \((u_H, p_H) \in X_H \times Y_H\) by (4.1).

Step 2. On the fine mesh \(T_h\), solve the stabilized linear Stokes problem.
Find \((u_h^h, p_h^h) \in X_h \times Y_h\) such that, for all \((v_h, q_h) \in X_h \times Y_h\),

\[
B_h\left((u_h^h, p_h^h); (I_h^* v_h, q_h)\right) + b_h\left(u_h^h, u_H, I_h^* v_h\right) + b_h\left(u_H, u_h^h, I_h^* v_h\right) = (f, I_h^* v_h) + b_h(u_H, u_H, I_h^* v_h).
\]

(4.7)

Now, we will study the convergence of the Newton two-level stabilized finite element solution \((u_h^h, p_h^h)\) to \((u, p)\) in some norms. To do this, let us set \(e = R_h(u, p) - u_h^h\), \(E = u - R_h(u, p),\) and \(\eta = Q_h(u, p) - p_h^h\).

Theorem 4.4. Under the assumptions of Theorems 3.2, 3.4, 3.5, and 3.6 for \(H\) and \(h\), the Newton two-level stabilized FVE solution \((u_h^h, p_h^h)\) satisfies the following error estimates:

\[
\left|u - u_h^h\right|^1 + \|p - p_h^h\|^1_0 \leq C\left(h + |\log h|^{1/2}H^3\right).
\]

(4.8)
Proof. Subtracting (4.7) from (2.25), using the Galerkin projection (3.12) and taking \((v_h, q_h) = (e, \eta)\), we get

\[
\begin{align*}
B_h((e, \eta); (I_h^* e, \eta)) + b(E, u, e) + b(R_h - u_H, u - u_H, e) + b(u_H, E, e) \\
- \bar{b}(R_h - u_H, R_h - u_H, e - I_h^* e) - \bar{b}(R_h, R_h - u, e - I_h^* e) - \bar{b}(R_h, u, e - I_h^* e) \\
- b(e, u_H, e) + \bar{b}(e, u_H, e - I_h^* e) + \bar{b}(u_H, e, e - I_h^* e) &= (f, e - I_h^* e). 
\end{align*}
\]  

(4.9)

Using Lemma 3.1 and Theorems 3.2, 3.5, and 3.7, we obtain

\[
\begin{align*}
|b(E, u, e) + b(u_H, E, e) + (f, e - I_h^* e)| &\leq C(|u_1| + |u_{H1}|)|E|_1 + \|f\|_0 \|e - I_h^* e\|_0 \\
&\leq Ch|e|_1, \\
|b(R_h - u_H, u - u_H, e)| &= |b(R_h - u_H, e, u - u_H)| \\
&\leq C|\log h|^{1/2}|R_h - u_H| |e|_1 |u - u_H|_0 \\
&\leq C|\log h|^{1/2}|R_h - u_1| + |u - u_H| |e|_1 |u - u_H|_0 \\
&\leq C|\log h|^{1/2} H^3 |e|_1. 
\end{align*}
\]  

(4.10)

\[
\begin{align*}
|\bar{b}(R_h - u_H, R_h - u_H, e - I_h^* e)| &\leq C|\log h|^{1/2}|R_h - u_H| |R_h - u_H|_1 \|e - I_h^* e\|_0 \\
&\leq C|\log h|^{1/2} H^3 |e|_1. 
\end{align*}
\]  

(4.11)

\[
\begin{align*}
|\bar{b}(R_h, R_h - u, e - I_h^* e)| &\leq N|R_h|_1 |R_h - u|_1 |e|_1 \leq Ch|e|_1, \\
|\bar{b}(R_h, u - e - I_h^* e)| &\leq C|R_h|_1 \|u\|_2 \|e - I_h^* e\|_0 \leq Ch|e|_1 \leq Ch|e|_1, \\

\forall |e|_1^2 - |b(e, u_H, e)| - |\bar{b}(e, u_H, e - I_h^* e)| - |\bar{b}(u_H, e, e - I_h^* e)| \\
&\geq \nu |e|_1^2 - 3N|u_H|_1 |e|_1^2 \\
&\geq \nu \left(1 - \frac{3N}{\nu^2} \|f\|_{-1}\right) |e|_1^2. 
\end{align*}
\]  

(4.12)

(4.13)

(4.14)

(4.15)

Combining (4.10)–(4.15) with (4.9) yields

\[
|e|_1 \leq C\left(h + |\log h|^{1/2} H^3\right). 
\]  

(4.16)
Thanks to (3.7), (4.9), Theorems 3.2 and 3.5, and estimates (4.10)–(4.14) and (4.16), we have

\[
\|\eta\|_0 \leq (a_1)^{-1} \sup_{(e,\eta) \in X_h \times Y_h} \frac{B_h((e,\eta); (I_h^*v_h, q_h))}{\|v_h\|_1 + \|q_h\|_0} \\
\leq C \left( h + \log |h|^{1/2} H^3 + |e|_1 \right) \\
\leq C \left( h + \log |h|^{1/2} H^3 \right).
\]

Combining (4.16) and (4.17) with (3.14) and Theorem 3.2 yields (2.13).
