An approximate scheme is defined for incompressible miscible displacement in porous media. This scheme is constructed by using immersed interface finite element method for the pressure equation which is based on the broken P_1 -nonconforming piecewise linear polynomials on interface triangular elements and utilizing finite element method for the concentration equation. Error estimates for pressure in broken H^1 norm and for concentration in L^2 norm are presented.

1. Introduction

Miscible displacement of one incompressible fluid in a porous medium Ω over time interval $J = [0, T]$ is modeled by the system

$$\begin{aligned} (a) \quad & -\nabla \cdot (\alpha(c) \nabla p) = \nabla \cdot u = q, \quad x \in \Omega, \quad t \in J, \\ (b) \quad & \phi \frac{\partial c}{\partial t} + u \cdot \nabla c - \nabla \cdot (D(u) \nabla c) \\ & = (\tilde{c} - c) q = g(x, t, c), \quad x \in \Omega, \quad t \in J, \\ (c) \quad & u \cdot n = D(u) \nabla c \cdot n = 0, \quad x \in \partial\Omega, \quad t \in J, \\ (d) \quad & c(x, 0) = c_0(x), \quad x \in \Omega. \end{aligned} \quad (1)$$

In the formulation, we have utilized the fact that in applications the vertical dimension of a subsurface geological formation is often much smaller than the horizontal dimension. We thus simplify the problem via a vertical average to rewrite the problem as a two-dimensional problem in the horizontal dimension, so the physical domain $\Omega \subset \mathbb{R}^2$. $\alpha(c) = \alpha(x, c) = k(x)/\mu(c)$, $k(x)$ is the permeability tensor of the medium and $\mu(c)$ is the viscosity of the fluid mixture that may be discontinuous across some interfaces; $\phi(x)$ is the porosity of the medium; $u(x, t)$ is the Darcy velocity of the mixture; $q(x, t)$ represents flow rates at wells, commonly a linear

combination of Dirac measures; $D(u) = D(x, c, \nabla p) = \phi(x)\{d_m I + |u|(d_l E(u) + d_t E^T(u))\}$ is the diffusion-dispersion tensor, with d_m , d_l , and d_t being the molecular diffusion, the transverse, and longitudinal dispersivities, respectively, I is the identity tensor; $\tilde{c}(x, t)$ is specified at sources and $\tilde{c}(x, t) = c(x, t)$ at sinks. $c_0(x, t)$ is the initial concentration. The dependent variable is $p(x, t)$ is the pressure in the fluid mixture, and $c(x, t)$ is the concentration of a solvent injected into resident reservoir.

For (1) we assume that

$$(q, 1) = \int_{\Omega} q(x, t) dx = 0, \quad t \in J. \quad (2)$$

Let $u = u(x, c, \nabla p) = (u_1(x, c, p_x), u_2(x, c, p_y))$; for some $\hat{\varepsilon} > 0$ restrict the variable q_1 to lie between $-\hat{\varepsilon} \leq q_1 \leq 1 + \hat{\varepsilon}$ and $q_2 \in \mathbb{R}$, so we can suppose that the following regularity for α , D , ϕ , and u holds:

$$\begin{aligned} 0 < \alpha_* &\leq \alpha(x, q_1) \leq \alpha^*, \\ D_* &\leq D(u) \leq D^*, \\ \phi_* &\leq \phi(x) \leq \phi^*; \end{aligned} \quad (3)$$

$$|u_i(x, q_1, q_2)| \leq K(1 + |q_2|), \quad i = 1, 2, \quad q_2 \in \mathbb{R}. \quad (4)$$

There exist much literature concerning numerical method and numerical analysis of miscible placement problem in

porous media, for example, [1–4], and so on. As we know the porous media equations used to model the interface between oil and an injected fluid in simulations of secondary recovery in oil reservoirs. For the pressure equation (1)(a), the coefficient $\alpha(c)$ often changes rapidly across fluid interfaces, and this sharp change is accompanied by large changes in the pressure gradient, as a compensatory, yielding a fairly smooth Darcy velocity u , so we can trade (1)(a) as an interface problem. When the interface is smooth enough, the solution of the interface problem is also very smooth in individual regions where the coefficient is smooth, but due to the jump of the coefficient across the interface, the global regularity is usually very low and has order of $H^{1+\gamma}$, $0 < \gamma < 1$. Due to the low global regularity and the irregular geometry of the interface, it seems to be difficult for the standard finite element method to achieve high accuracy.

For better approximation, the fitted finite element methods whose mesh depends on the smooth interface are developed [5]. However, this method using fitted grids is costly for more complicated time dependent problems in which the interface moves with time and repeated grid generation is called for. Compared with the fitted finite element methods, the immersed interface method proposed by LeVeque and Li [6] allows the mesh to be independent of the interface, such as a Cartesian mesh. In recent years, Li et al. [7] studied an immersed finite element method using uniform grid, and they proved the approximation property of the finite element space of this scheme. On the other hand, Kwak et al. [8] introduced an immersed finite element method based on the broken P_1 -nonconforming piecewise linear polynomials on interface triangular elements; this method uses edge averages as degrees of freedom, and the basis functions are C-R type [9]. Theory analysis and numerical experiments also show the optimal-order convergence of the method.

In this paper, we apply P_1 -nonconforming finite element method (P_1 FEM) to pressure equation, while a FEM was used to approximate the concentration equation. Other methods could also be employed for the discretization of the concentration equation, for example, characteristic Galerkin method and so on. However, since the main point of this paper is to show the feasibility of the use of P_1 FEM for pressure, we will discuss the concentration equation in the single case.

The rest of the paper is organized as follows: in Section 2, we first introduce some preliminaries. In Section 3, we briefly describe the P_1 FEM-FEM scheme. In Section 4, we present some projections and lemmas used in the following error analysis. In Section 5, we prove the main error estimate.

2. Preliminaries

In this paper, without loss of generality, we consider the case in which $\Omega \subset \mathbb{R}^2$ is a rectangular domain and the interface Γ is a smooth curve separating Ω into two subdomains Ω^+ and Ω^- such that $\bar{\Omega} = \bar{\Omega}^+ \cup \bar{\Omega}^- \cup \Gamma$; see Figure 1 for an illustration.

The proper jump conditions for elliptic (1)(a) are given by

$$[p] = 0, \quad [\alpha(c) \nabla p \cdot n] = 0 \quad \text{across } \Gamma, \quad (5)$$

FIGURE 1

where $p \in H^1(\Omega)$. We assume $\alpha(c)$ is a positive function bounded below and above by two positive constants.

Let $W_q^m(\Omega)$, $1 \leq q \leq +\infty$, be the Sobolev spaces consisting of functions whose derivatives up to order m are q th integrable on Ω , and $H^m(\Omega) := W_2^m(\Omega)$ and $H^0(\Omega) = L^2(\Omega)$.

For the analysis, we introduce the space

$$\tilde{H}^2(\Omega) = \{p \in H^1(\Omega); p \in H^2(\Omega^s), s = +, -\}, \quad (6)$$

equipped with the norm

$$\begin{aligned} \|p\|_{\tilde{H}^2(\Omega)}^2 &= \|p\|_{H^2(\Omega^+)}^2 + \|p\|_{H^2(\Omega^-)}^2, \\ |p|_{\tilde{H}^2(\Omega)}^2 &= |p|_{H^2(\Omega^+)}^2 + |p|_{H^2(\Omega^-)}^2, \\ \forall p &\in \tilde{H}^2(\Omega). \end{aligned} \quad (7)$$

We integrate (1)(a) multiplied by any test function $v \in H^1(\Omega)$ over the domain Ω and apply the divergence theorem; then the variational formulation of the pressure equation is as follows Find $p \in H^1(\Omega)$ such that

$$a(p, v) = (q, v), \quad v \in H^1(\Omega), \quad (8)$$

where the bilinear formation $a(p, v) = (\alpha(c) \nabla p, \nabla v)$.

By the Sobolev embedding theorem, for any $p \in \tilde{H}^2(\Omega)$, we can get $p \in W_s^1(\Omega)$ for any $s > 2$. Then we have the following regularity lemma for the weak solution p of the variational formulation (8).

Lemma 1 (see [10]). *Assume that $q \in L^2(\Omega)$. Then there exists a unique solution $p \in \tilde{H}^2(\Omega)$ to the variational formulation (8) such that*

$$\|p\|_{\tilde{H}^2(\Omega)} \leq \|q\|_{L^2(\Omega)}. \quad (9)$$

3. Formation of the Method

In this section, firstly, we define a broken P_1 -nonconforming finite element method for pressure equation, and then, we use a finite element method to approximate the concentration equation.

In order to construct a broken P_1 -nonconforming finite element procedure for pressure equation (1)(a), we assume the following situation.

Let T_h be the usual regular triangulation of the domain Ω such that the elements have diameters bounded by h_p . Without loss of generality, we assume that the triangles in the partition used have the following features.

- (H₁) If Γ meets one edge at more than two points, then this edge is one part of Γ .
- (H₂) If Γ meets a triangle at two points, then the two points must be on the different edges of this triangle.
- (H₃) The interface curve Γ is defined by a piecewise C^2 function, and the mesh T_h is formed such that the subset of Γ in any interface element is C^2 .

Then we can separate the triangles of partition T_h into two classes. For an element $T \in T_h$, if the interface Γ passes through the interior of T , we call it an interface element and denote it by T_m ; otherwise, we call it a noninterface element and denote it by T_n , respectively.

As usual, we will define linear finite element spaces on each element of the partition T_h , so we have to construct the local basis functions. For a noninterface element T_n , we can simply use the standard linear shape functions on T_n with degrees of freedom at average values along edges e_j of T_n and construct the linear finite element space $\bar{S}_h(T_n)$ as follows:

$$\bar{S}_h(T_n) = \text{span} \left\{ \varphi_i : \varphi_i \in P_1(T_n), \right. \\ \left. \frac{1}{|e_j|} \int_{e_j} \varphi_i ds = \delta_{ij}, i, j = 1, 2, 3 \right\}. \quad (10)$$

For this space, we define the interpolation operator $I_h : H^2(T_n) \rightarrow \bar{S}_h(T_n)$, where the following well-known approximation property is satisfied:

$$\|p - I_h p\|_{L^2(T_n)} + h_p \|p - I_h p\|_{H^1(T_n)} \leq Ch_p^2 \|p\|_{H^2(T_n)}, \quad (11)$$

and we use $\bar{S}_h(\Omega_n)$ to denote the space of piecewise P_1 -non-conforming finite element space on the domain $\Omega_n = \bigcup T_n$.

For interface element T_m , since the finite element space on a general element can be obtained from the counterpart of a reference element through an affine mapping, we consider a typical interface element T_m whose geometric configuration is given in Figure 2 in which the three vertices are given by $A_1 = (0, 0)$, $A_2 = (1, 0)$, and $A_3 = (0, 1)$, and the curve between points D and E is part of the interface with $D = (0, a)$ for $0 < a \leq 1$ and $E = (b, 0)$ for $0 < b \leq 1$. Let $\overline{DE}$ denote the line segment connecting points D and E , which divides T_m into two parts T_m^+ and T_m^- with $T_m = T_m^+ \cup T_m^- \cup \overline{DE}$.

Let e_i , $i = 1, 2, 3$ be the edges of T_m , and let $\bar{\varphi}_{e_i}$ denote the average of φ along e_i , that is, $\bar{\varphi}_{e_i} = (1/|e_i|) \int_{e_i} \varphi ds$, $\varphi \in H^1(T_m)$, and then we would like to construct a new function which is linear on T_m^+ and T_m^- , respectively, and satisfies the jump condition (5) on $\overline{DE}$. For this purpose, we write the modified basis function $\hat{\varphi}$ on an interface element T_m as follows:

$$\hat{\varphi} = \begin{cases} \hat{\varphi}^- = a_0 + b_0 x + c_0 y, & \text{in } T_m^-, \\ \hat{\varphi}^+ = a_1 + b_1 x + c_1 y, & \text{in } T_m^+, \end{cases} \quad (12)$$

FIGURE 2

with the following constraints:

$$\begin{aligned} \bar{\varphi}_{e_i} &= V_i, \quad i = 1, 2, 3, \\ \hat{\varphi}^-(D) &= \hat{\varphi}^+(D), \\ \hat{\varphi}^-(E) &= \hat{\varphi}^+(E), \\ \bar{\alpha}^- \frac{\partial \hat{\varphi}^-}{\partial n_{\overline{DE}}} &= \bar{\alpha}^+ \frac{\partial \hat{\varphi}^+}{\partial n_{\overline{DE}}}, \end{aligned} \quad (13)$$

where $\bar{\alpha}^-$, $\bar{\alpha}^+$ are averages along $\overline{DE}$ and $\rho = \bar{\alpha}^-/\bar{\alpha}^+$, V_i , $i = 1, 2, 3$, are given values, and $n_{\overline{DE}}$ is the unit normal vector on the line $\overline{DE}$, that is, $n_{\overline{DE}} = (a, b)/\sqrt{a^2 + b^2}$.

By similar calculation to that given in Theorem 2.2 of [8], we can rewrite (12) and (13) in the matrix form:

$$A \begin{pmatrix} a_0 \\ b_0 \\ c_0 \\ a_1 \\ b_1 \\ c_1 \end{pmatrix} = \begin{pmatrix} V_1 \\ V_2 \\ V_3 \\ 0 \\ 0 \\ 0 \end{pmatrix}, \quad (14)$$

where the coefficient matrix is defined by

$$A = \begin{pmatrix} 0 & 0 & 0 & 1 & \frac{1}{2} & \frac{1}{2} \\ a & 0 & \frac{1}{2}a^2 & 1-a & 0 & \frac{1}{2}(1-a^2) \\ b & \frac{1}{2}b^2 & 0 & 1-b & \frac{1}{2}(1-b^2) & 0 \\ 1 & 0 & a & -1 & 0 & -ah_2 \\ 1 & b & 0 & -1 & -b & 0 \\ 0 & \rho a & \rho b & 0 & -a & -b \end{pmatrix}, \quad (15)$$

and the determinant of the matrix A is

$$\begin{aligned} \det(A) &= -\frac{1}{4}a^3b + \frac{1}{4}a^3bp - \frac{1}{4}a^2\rho \\ &\quad - \frac{1}{4}ab^3 + \frac{1}{4}ab^3\rho - \frac{1}{4}b^2\rho \\ &= \frac{1}{4}(a^2 + b^2)\{\rho(ab - 1) - ab\} < 0. \end{aligned} \quad (16)$$

Therefore, the coefficients of (12) are uniquely determined by conditions $\widehat{\varphi}_{e_i} = V_i$, $i = 1, 2, 3$, respectively, and when V_i , $i = 1, 2, 3$, have the same value V , we can get the piecewise linear function $\widehat{\varphi} = V$ by uniqueness.

Therefore we can define the following finite element space on an interface element T_m :

$$\begin{aligned} \widehat{S}_h(T_m) \\ = \text{span}\{\widehat{\varphi} : \widehat{\varphi}|_{T_m} \text{ is well defined by the above construction}\}. \end{aligned} \quad (17)$$

Also we use $\widehat{S}_h(\Omega_m)$ to denote the finite element space defined on the domain $\Omega_m = \bigcup T_m$.

Remark 2. Although for functions in $\widehat{S}_h(T_m)$, the flux jump condition is enforced on line segments, they actually satisfy a weak flux jump condition along the interface Γ when α is a piecewise constant such that

$$\int_{\Gamma \cap T} (\alpha^- \nabla \varphi^- - \alpha^+ \nabla \varphi^+) \cdot n_T ds = 0, \quad \forall \varphi \in \widehat{S}_h(T_m), \quad (18)$$

which is proved by an application of divergence theorem as in [11].

Combining the definitions of $\widehat{S}_h(\Omega_n)$ and $\widehat{S}_h(\Omega_m)$, we can describe the immersed finite element space $\widehat{S}_h(\Omega)$ on the whole domain Ω ,

$$\widehat{S}_h(\Omega) = \{\widehat{\varphi} : \widehat{\varphi}|_{\Omega_n} \in \widehat{S}_h(\Omega_n), \widehat{\varphi}|_{\Omega_m} \in \widehat{S}_h(\Omega_m)\}, \quad (19)$$

endowed with the broken norm,

$$\|\widehat{\varphi}\|_{1,h}^2 = \sum_T \int_T |\nabla \widehat{\varphi}|^2 dx, \quad \widehat{\varphi} \in \widehat{S}_h(\Omega). \quad (20)$$

Now, assume that the approximation of concentration C is known. Then, the pressure $P \in \widehat{S}_h(\Omega)$ can be determined by the following system:

$$a_h(P, \widehat{\varphi}) = (q, \widehat{\varphi}), \quad \widehat{\varphi} \in \widehat{S}_h(\Omega), \quad (21)$$

where $a_h(P, \widehat{\varphi}) = \sum_{T \in T_h} \int_T \alpha(C) \nabla P \nabla \widehat{\varphi} dx$ is the bilinear formulation defined on $H_h(\Omega) \times H_h(\Omega)$ with $H_h(\Omega) = H^1(\Omega) \oplus \widehat{S}_h(\Omega)$.

The question at hand is to discretize the concentration equation.

Multiplying the concentration equation (1)(b) by a test function $v \in H^1(\Omega)$ and integrating over Ω which leads to the following weak formulation for concentration c :

$$\begin{aligned} \left(\phi \frac{\partial c}{\partial t}, v \right) + (u(c, \nabla p) \cdot \nabla c, v) + (D(c, \nabla p) \nabla c, \nabla v) \\ = (g(c), v), \quad v \in H^1(\Omega). \end{aligned} \quad (22)$$

Let M_h denote the standard piecewise linear finite element space associated with T_h , and h_c denote the bound of elements diameters. Then the discrete procedure of (22) is to find $C : J \rightarrow M_h$ such that

$$\begin{aligned} \left(\phi \frac{\partial C}{\partial t}, v_h \right) + (u(C, \nabla P) \cdot \nabla C, v_h) + (D(C, \nabla P) \nabla C, \nabla v_h) \\ = (g(C), v_h), \quad v_h \in M_h, \\ C(x, 0) = \widetilde{c}_0(x), \quad x \in \Omega, \end{aligned} \quad (23)$$

where $\widetilde{c}_0(x)$ is the elliptic projection of $c_0(x)$.

4. Projection and Some Lemmas

For convergence analysis conducted in the following section, we need an interpolation operator $I_h : \widetilde{H}^2(T) \rightarrow \widetilde{S}_h(T)$ using the average of p on each edge by

$$(\overline{I_h p})_{e_i} = \overline{p}_{e_i}, \quad i = 1, 2, 3, \quad (24)$$

and when $p \in \widetilde{H}^2(\Omega)$, we can define $I_h p$ by $(I_h p)|_T = I_h(p|_T)$. Then the following interpolation estimate hold for the P_1 FEM approximation [8]

$$\begin{aligned} \|p - I_h p\|_{L^2(\Omega)} + h_p \|p - I_h p\|_{1,h} \\ \leq Ch_p^2 \|p\|_{\widetilde{H}^2(\Omega)}, \quad \forall p \in \widetilde{H}^2(\Omega). \end{aligned} \quad (25)$$

Next, let $\widetilde{C} : J \rightarrow M_h$ be the elliptic projection of c defined by

$$\begin{aligned} (u(c, \nabla p) \cdot \nabla (\widetilde{C} - c), v_h) + (D(c, \nabla p) \nabla (\widetilde{C} - c), \nabla v_h) \\ + (\lambda(\widetilde{C} - c), v_h) = 0, \quad \forall v_h \in M_h. \end{aligned} \quad (26)$$

The function λ will be chosen to assure coercivity of the form. Then, the following estimates hold [12]:

$$\begin{aligned} \|c - \widetilde{C}\|_{L^2(\Omega)} + h_c \|c - \widetilde{C}\|_{H^1(\Omega)} \leq Kh_c^2 \|c\|_{H^2(\Omega)}, \\ \left\| \frac{\partial(c - \widetilde{C})}{\partial t} \right\|_{L^2(\Omega)} \leq Kh_c^2 \left\{ \|c\|_{H^2(\Omega)} + \left\| \frac{\partial c}{\partial t} \right\|_{H^2(\Omega)} \right\}. \end{aligned} \quad (27)$$

For convergence analysis conducted in Section 5, we need to apply quote some lemmas from [9, 13] and references therein.

Lemma 3 (see [9] (the second Strang lemma)). *Let p and P be the solution of (8) and (21). Then there exists a constant $C > 0$ such that*

$$\begin{aligned} & \|p - P\|_{1,h} \\ & \leq C \left\{ \inf_{w_h \in \tilde{S}_h(\Omega)} \|p - w_h\|_{1,h} + \sup_{\tilde{\varphi} \in \tilde{S}_h(\Omega)} \frac{|a_h(p, \tilde{\varphi}) - (q, \tilde{\varphi})|}{\|\tilde{\varphi}\|_{1,h}} \right\}. \end{aligned} \quad (28)$$

Lemma 4 (see [13]). *Let e be an edge of T . Then there exists a constant $C > 0$ such that for all $\varphi, v \in H^1(T)$:*

$$\left| \int_e \varphi (v - \bar{v}_e) ds \right| \leq Ch_p |\varphi|_{1,T} |v|_{1,T}, \quad (29)$$

where $\bar{v}_e := (1/|e|) \int_e v ds$.

5. Convergence Analysis

In this section, we will present convergence analysis for the pressure and concentration.

Theorem 5. *Let $p \in \tilde{H}^2(\Omega)$, $P \in \tilde{S}_h(\Omega)$ be the solution of (8) and (21); then there exists a constant $K > 0$ independent of h_p and the location of the interface, such that the following result holds:*

$$\|p - P\|_{1,h} \leq Kh_p \|p\|_{\tilde{H}^2(\Omega)} + K \|c - C\|_{L^2(\Omega)}. \quad (30)$$

Proof. Since the immersed finite element formulation (21) is nonconforming, we can use Lemma 3 to prove the error bound. The first part in (28) is an approximation error, which can be estimated simply:

$$\inf_{w_h \in \tilde{S}_h(\Omega)} \|p - w_h\|_{1,h} \leq Kh_p \|p\|_{\tilde{H}^2(\Omega)}. \quad (31)$$

For the second part, it is a consistency error estimate. By the definition of $a_h(\cdot, \cdot)$ and Green's formula, we can get

$$\begin{aligned} & |a_h(p, \tilde{\varphi}) - (q, \tilde{\varphi})| \\ & = \left| \sum_{T \in T_h} \int_T \alpha(C) \nabla p \nabla \tilde{\varphi} dx - \int_{\Omega} q \tilde{\varphi} dx \right| \\ & = \left| \sum_{T \in T_h} \int_T \alpha(C) \nabla p \nabla \tilde{\varphi} dx \right. \\ & \quad \left. - \sum_{T \in T_h} \int_T \alpha(c) \nabla p \nabla \tilde{\varphi} dx \right. \\ & \quad \left. + \sum_{T \in T_h} \left\langle \alpha(c) \frac{\partial p}{\partial n}, \tilde{\varphi} \right\rangle_{\partial T} \right| \end{aligned}$$

$$\begin{aligned} & \leq \left| \sum_{T \in T_h} \int_T (\alpha(C) - \alpha(c)) \nabla p \nabla \tilde{\varphi} dx \right| \\ & \quad + \left| \sum_{T \in T_h} \left\langle \alpha(c) \frac{\partial p}{\partial n}, \tilde{\varphi} \right\rangle_{\partial T} \right| \\ & \leq \|\nabla p\|_{L^\infty(\Omega)} \|c - C\|_{L^2(\Omega)} \|\tilde{\varphi}\|_{1,h} \\ & \quad + \left| \sum_{T \in T_h} \left\langle \alpha(c) \frac{\partial p}{\partial n}, \tilde{\varphi} \right\rangle_{\partial T} \right| \\ & \leq K \|c - C\|_{L^2(\Omega)} \|\tilde{\varphi}\|_{1,h} \\ & \quad + \left| \sum_{T \in T_h} \left\langle \alpha(c) \frac{\partial p}{\partial n}, \tilde{\varphi} \right\rangle_{\partial T} \right|, \end{aligned} \quad (32)$$

where n is the unit outward normal vector on each ∂T , $\tilde{\varphi} \in \tilde{S}_h(\Omega)$, and by the construction of the space $\tilde{S}_h(\Omega)$ we have a well-defined property on the interior edges, that is, $\int_e \tilde{\varphi}|_{T_1} = \int_e \tilde{\varphi}|_{T_2}$ for e is the common edge of adjacent element T_1 and T_2 . By boundary condition, we note that $\alpha(c)(\partial p / \partial n)$ vanishing average on the boundary. So we rewrite $\sum_{T \in T_h} \langle \alpha(c)(\partial p / \partial n), \tilde{\varphi} \rangle_{\partial T}$ and use Lemma 4 to derive that

$$\begin{aligned} & \sum_{T \in T_h} \left\langle \alpha(c) \frac{\partial p}{\partial n}, \tilde{\varphi} \right\rangle_{\partial T} \\ & = \sum_{T \in T_h} \sum_{e \in \partial T} \left\langle \alpha(c) \frac{\partial p}{\partial n} - \overline{\alpha(c) \frac{\partial p}{\partial n}}, \tilde{\varphi} \right\rangle_e \\ & \leq \sum_{T \in T_h} Ch_p \left| \alpha(c) \frac{\partial p}{\partial n} \right|_{1,T} |\tilde{\varphi}|_{1,T} \\ & \leq Ch_p \|p\|_{\tilde{H}^2(\Omega)} \|\tilde{\varphi}\|_{1,h}. \end{aligned} \quad (33)$$

Combining (28) with (31)–(33) yields the theorem result. $\square$

We now are in the position to prove the error estimate for concentration.

Theorem 6. *Assume that the true solution (c, p) of (1) satisfies $c \in L^\infty(H^2) \cap L^2(H^2)$, $p \in L^2(\tilde{H}^2)$. Let $\tilde{C}$ be the projection of c satisfying (26) and let C be the solution of (23). Suppose that the mesh parameters satisfy $h_c^2 = O(h_p)$. Then the following result holds:*

$$\|C - \tilde{C}\|_{L^\infty(L^2)} + \|\nabla(C - \tilde{C})\|_{L^2(L^2)} \leq K(h_c^2 + h_p). \quad (34)$$

Proof. We decompose the error $c - C$ to $\xi = C - \tilde{C}$, and $\eta = c - \tilde{C}$. Then, combining (22), (23), and (26) results in the following error equation for the concentration:

$$\begin{aligned} & \left(\phi \frac{\partial \xi}{\partial t}, v_h \right) + (D(C, \nabla P) \nabla \xi, \nabla v_h) \\ & = \left(\phi \frac{\partial \eta}{\partial t}, v_h \right) - (\lambda \eta, v_h) + (g(C) - g(c), v_h) \end{aligned}$$

$$\begin{aligned}
& - (u(C, \nabla P) \nabla \xi, v_h) \\
& + ((D(c, \nabla p) - D(C, \nabla P)) \nabla \bar{C}, \nabla v_h) \\
& + ((u(c, \nabla p) - u(C, \nabla P)) \nabla \bar{C}, v_h).
\end{aligned} \tag{35}$$

We choose the test function as $v_h = \xi$ in (35) and integrate from 0 to t on both sides to derive

$$\begin{aligned}
& \int_0^t \left(\phi \frac{\partial \xi}{\partial t}, \xi \right) d\tau + \int_0^t (D(C, \nabla P) \nabla \xi, \nabla \xi) d\tau \\
& = \int_0^t \left(\phi \frac{\partial \eta}{\partial t}, \xi \right) d\tau - \int_0^t (\lambda \eta, \xi) d\tau \\
& + \int_0^t (g(C) - g(c), \xi) d\tau \\
& - \int_0^t (u(C, \nabla P) \nabla \xi, \xi) d\tau \\
& + \int_0^t ((D(c, \nabla p) - D(C, \nabla P)) \nabla \bar{C}, \nabla \xi) d\tau \\
& + \int_0^t ((u(c, \nabla p) - u(C, \nabla P)) \nabla \bar{C}, \xi) d\tau.
\end{aligned} \tag{36}$$

The terms on the left side can be easily bounded by

$$\begin{aligned}
& \int_0^t \left(\phi \frac{\partial \xi}{\partial t}, \xi \right) d\tau + \int_0^t (D(C, \nabla P) \nabla \xi, \nabla \xi) d\tau \\
& \geq \frac{1}{2} \phi^* \|\xi\|^2 + D_* \int_0^t \|\nabla \xi\|^2 d\tau.
\end{aligned} \tag{37}$$

Next, we should estimate terms on the right side one by one.

By (27), it is trivial that

$$\left| \int_0^t \left(\phi \frac{\partial \eta}{\partial t}, \xi \right) d\tau \right| \leq K \left(h_c^4 + \int_0^t \|\xi\|^2 d\tau \right). \tag{38}$$

Similarly, we can bound the second and third terms as follows:

$$\begin{aligned}
& \left| \int_0^t (\lambda \eta, \xi) d\tau \right| \leq K \left(h_c^4 + \int_0^t \|\xi\|^2 d\tau \right), \\
& \int_0^t (g(C) - g(c), \xi) d\tau \leq K \left(h_c^4 + \int_0^t \|\xi\|^2 d\tau \right),
\end{aligned} \tag{39}$$

provided that g is Lipschitz continuous.

For the fifth term, we can derive the estimate by using the boundness of $\bar{C}$ and (27), as well as (30),

$$\begin{aligned}
& \left| \int_0^t ((D(c, \nabla p) - D(C, \nabla P)) \nabla \bar{C}, \nabla \xi) d\tau \right| \\
& \leq K \|\nabla \bar{C}\|_{L^\infty(L^\infty)} \int_0^t (\|\xi\| + \|\eta\| + \|p - P\|_{1,h}) \|\nabla \xi\| d\tau \\
& \leq K \int_0^t (\|\xi\| + h_c^2 + h_p^2) \|\nabla \xi\| d\tau \\
& \leq K \left(\int_0^t \|\xi\|^2 d\tau + h_c^4 + h_p^4 \right) + \frac{D_*}{4} \int_0^t \|\nabla \xi\|^2 d\tau.
\end{aligned} \tag{40}$$

Similarly, we can derive

$$\begin{aligned}
& \left| \int_0^t ((u(c, \nabla p) - u(C, \nabla P)) \nabla \bar{C}, \xi) d\tau \right| \\
& \leq K \left(h_c^4 + h_p^2 + \int_0^t \|\xi\|^2 d\tau \right).
\end{aligned} \tag{41}$$

In order to prove the forth term, we need the following induction hypothesis:

$$\|\nabla P\|_{L^\infty(L^\infty)} \leq K^*. \tag{42}$$

As the statement in [1], we assume that for some $\varepsilon > 0$, $\varepsilon \leq \bar{\varepsilon}$,

$$-\varepsilon \leq C \leq 1 + \varepsilon \tag{43}$$

and with this hypothesis and (4), we can get

$$\begin{aligned}
& \left| \int_0^t (u(C, \nabla P) \nabla \xi, \xi) d\tau \right| \\
& \leq K (\|\nabla P\|_{L^\infty(L^\infty)} + 1)^2 \\
& \quad \times \int_0^t \|\xi\|^2 d\tau + \frac{D_*}{4} \int_0^t \|\nabla \xi\|^2 d\tau \\
& \leq K \int_0^t \|\xi\|^2 d\tau + \frac{D_*}{4} \int_0^t \|\nabla \xi\|^2 d\tau.
\end{aligned} \tag{44}$$

Therefore, collecting all the bounds derived above and using Gronwall inequality leads to

$$\|\xi\|_{L^\infty(L^2)}^2 + \|\nabla \xi\|_{L^2(L^2)}^2 \leq K (h_c^4 + h_p^2). \tag{45}$$

To complete the argument, we have to check hypothesis (42). We use (25), (27), (30), (45), inverse inequality, and boundness of $I_h p$ to get that

$$\begin{aligned}
\|\nabla P\|_{L^\infty(L^\infty)} & \leq \|\nabla (P - I_h p)\|_{L^\infty(L^\infty(T))} \|\nabla I_h p\|_{L^\infty(L^\infty(T))} \\
& \leq K + K h_p^{-1} \sum_{T \in \mathcal{T}_h} \|\nabla (P - I_h p)\|_{L^\infty(L^2(T))}
\end{aligned}$$

$$\begin{aligned}
&\leq K + Kh_p^{-1} \{ \|P - p\|_{L^\infty(1,h)} + \|p - I_h p\|_{L^\infty(1,h)} \} \\
&\leq K + Kh_p^{-1} \{ h_p + h_c^2 \} \\
&\leq K^*.
\end{aligned} \tag{46}$$

□

Combining (27) with (30) and (45), we deduce the error estimates for the pressure and the concentration.

Theorem 7. Assume that the true solution (c, p) of (1) satisfies $c \in L^\infty(H^2) \cap L^2(H^2)$, $p \in L^2(\tilde{H}^2)$. Let C, P be the solution of (23) and (21). Suppose that the mesh parameters satisfy $h_c^2 = O(h_p)$. Then the following result holds:

$$\begin{aligned}
\|p - P\|_{L^\infty(1,h)} + \|c - C\|_{L^\infty(L^2)} &\leq K(h_c^2 + h_p), \\
\|\nabla(c - C)\|_{L^2(L^2)} &\leq K(h_c + h_p).
\end{aligned} \tag{47}$$

Remark 8. In this paper, we just get a priori error estimates for the coefficient $D = D(x, c, \nabla p)$. However, some mathematical models for miscible displacements, which are currently being used by oil companies, make the assumption that the coefficient $D = D(x, c)$ and it does not depend on ∇p ; with this assumption, we can prove the optimal order convergence similarly.
