The firefighting operation motion has an important impact on the safety and comfort of firefighting operation. As a judgment criterion of the firefighting efficiency, the comfort level is hard to judge in that it is completely decided by human feeling, so the comprehensive fuzzy evaluation is utilized for evaluation of comfort level. In this paper, firstly the factor and judgment set of firefighting operation comfort level are determined, and the fuzzy weight evaluation is obtained by questionnaires and analytic hierarchy process. Secondly, the joint angles of some particular motions are determined by motion capture equipment, the moment is obtained by ergonomic engineering software, and then the comprehensive comfort evaluation on firefighting operation motion is completed. Finally, the objective evaluation system of firefighting operation comfort is established.

1. Introduction

Firefighting grows more and more difficult owing to many types of fire accidents nowadays. The operation efficiency becomes the important factor on the firefighting according to statistics of fire accidents. Therefore, the rationality and reliability of firefighting operation directly affect the rescue work.

Motion analysis can be used to optimize and standardize human operation motion by means of detecting and tracking human operation. The motion analysis of firefighting is based on the collection, classification, and evaluation of particular rescue motion of fire men and the research results will be the fundamentals for firefighting product design and fire man training optimization. The motion analysis can be classified into two methods: visual motion observation method and image motion observation method [1].

The ergonomics analysis of firefighting operation and fire men mainly focuses on firefighting training, fire extinguisher, and fire man uniforms. Jiao et al. applied BP neural network to firefighting training evaluation. The comprehensive evaluation on the basic information, training methods, training contents, training management, and achievement of the tested groups are discussed [2]. Based on SAQ+B (Scenario Animation Question and Browse), Chen and Li proposed an evaluation method for simulation of firefighting training.

The training process is first divided into several units, and then the training problems are abstracted. Through experts grading, integrating calculation method of AHP by Matlab, the firefighting training evaluation is divided into two parts of knowledge acquisition and capability test. Therefore the quantitative estimation for the training subject is obtained [3]. AHP is short for analytic hierarchy, which is to process a structured technique for organizing and analyzing complex decisions. Comprehensive fuzzy evaluation is applied in plenty of areas. For ergonomic evaluation, Hongzhe and Damin utilized this method in evaluating the comfort level of fighter plane cockpit arrangement. Park et al. conducted evaluation on the comfort level of cab in engineering machines [4].

In the paper, evaluation model for firefighting operation motion will be built by fuzzy integrating method. The human body modeling and motion simulation will be conducted in virtual environment. Through motion capture equipment, the human biomechanics data will be obtained and then an ergonomic software is used for motion simulation, the comfort level judgment for typical firefighting motions. The paper connects the subjective perception and the objective evaluation of firefighters and implements the comfort judgment based on human factors, which play a quite significant role in modern industry [5].

2. Basic Ideas of Comprehensive Fuzzy Evaluation

2.1. Definition of Comfort Level. The comfort level can be defined as follows from the judgment of joint:

$$U = \frac{\tau(\alpha)_{\max,i} - \tau_{ci}}{\tau(\alpha)_{\max,i}}, \quad (1)$$

where τ_{ci} is actual moment of joint, $\tau(\alpha)_{\max,i}$ is joint, and i is maximum moment angel α .

From above, it is clear to see that what influences human comfort the most is the relationship between joint maximum moment and actual moment, and the less the actual moment the better the comfort. The comfort judgment set of firefighting operation is established as follow:

$$V = \{v_1, v_2, v_3\}, \quad (2)$$

where V_i ($i = 1, 2, 3$) represents all possible judgment results and $\{v_1, v_2, v_3\} = \{\text{Comfortable}, \text{Medium}, \text{Uncomfortable}\}$.

2.2. Determination of Membership Function. Membership function is used to describe fuzzy set. Research indicates that the energy utilization rate comes to maximum if half used [6], thus human will not feel tired even when working longer. The membership function is described in Figure 1.

In this figure, the membership function of U to fuzzy "comfort" is shown in

$$\mu_A(U) = \begin{cases} 0, & U < 0.5, \\ \frac{U-0.5}{0.2}, & 0.5 \leq U \leq 0.7, \\ 1, & U > 0.7. \end{cases} \quad (3)$$

2.3. Determination of Factors Set That Influences Motion Comfort. This paper mainly takes body movement into account. Human body consists of joints, which move in different degrees of freedom and combine into motions. Therefore, the judgment factors set is established based on joint movements in the comprehensive comfort evaluation for firefighters (Figure 2).

This evaluation model is a multilevel one, to begin with, conducting first-order evaluation on joint degree of freedom, then the second-order and stepping up, and finally obtaining comprehensive comfort evaluation [7]. The single factor evaluation matrix R is established based on the definition of comfort level and fuzzy membership function. One has

$$R = \begin{bmatrix} r_{11} & r_{12} & r_{13} \\ r_{21} & r_{22} & r_{23} \\ r_{31} & r_{32} & r_{33} \\ \dots & \dots & \dots \\ r_{n1} & r_{n2} & r_{n3} \end{bmatrix}. \quad (4)$$

Taking the first-order shoulder joint judgment, for instance, r_{ij} ($j = 1, 2, 3$) represents i ($i = 1, 2, 3$) in factor set U_{11} and membership to j in evaluation set V , and then making comprehensive fuzzy evaluation,

$$B = w \cdot R \quad (5)$$

FIGURE 1: Membership of comfort level in different evaluation indexes.

B is comprehensive fuzzy evaluation set in V ; w is the weight set for factor set U versus V . In the evaluation system, the importance level for the evaluation objectives is different, so fuzzy evaluation is applied to make clear the important parts when establishing evaluation objectives [8]. Weight coefficient is used to represent the importance of evaluation objectives. Three-level evaluation is applied taking comfort evaluation into consideration as shown in the following equations [9].

First-level comprehensive fuzzy evaluation method:

$$B_{\text{Shoulder}} = w_{111}R_{\text{UASS}} + w_{112}R_{\text{UAFE}} + w_{113}R_{\text{UAR}}, \quad (6)$$

$$B_{\text{Elbow}} = w_{121}R_{\text{FLE}}.$$

Second-level comprehensive fuzzy evaluation method:

$$B_{\text{Upper Limbs}} = w_{11}R_{\text{Shoulder}} + w_{12}R_{\text{Elbow}}, \quad (7)$$

$$B_{\text{Lower Limbs}} = w_{21}R_{\text{Hip}} + w_{22}R_{\text{Foot}} + w_{23}R_{\text{Knee}}.$$

Third-level comprehensive fuzzy evaluation method:

$$B = w_1R_{\text{Upper Limbs}} + w_2R_{\text{Lower Limbs}}. \quad (8)$$

To obtain the membership of operation motion to comfort level, subjective survey is requisite to acquire weight w , and the maximum moment and actual moment of joints are needed according to the comfort level formula. Thus, the first step is to conduct weight acquisition experiment, and the second is to calculate the joint motion angle and actual moment.

3. Weight Index Acquisition

3.1. Subjective Weight Investigation Experiment. When it comes to judge how much joints influence human comfort, joint movement is usually used. The questionnaire is completed through judging the body condition after finishing some movement, taking two joints into comparison. If the body comfort level is lower, which means that this very joint plays an important role in evaluating human body condition, this joint will score high.

FIGURE 2: Joints that influence comprehensive comfort level.

To guarantee the accuracy, this research will choose 0–4 scoring method and analytic hierarchy process from various weight set quantized value methods. First, conduct subjective questionnaires among 11 firefighters and use 0–4 scoring method, in which firefighters grade the factors with their subjective judgment. If they are of identical importance, they are 2 points each; if one is more important than the other, then 3 points and 1 point graded; and if one is far more important, then it is graded 4 points and the other 0. After that, analytic hierarchy process is used with the evaluation results by experts.

In accordance with the factor set of fuzzy evaluation, five parts including shoulder, elbow, hip, ankle, and knee joints need to be compared. Since human body is symmetrical distribution, so whether the left or right joint will fit the experiment.

- (1) The firefighters should be quite familiar with the procedure and requirement before the experiment.
- (2) The firefighters should keep up-right and relaxed and move a single joint with other joints fixed. The duration is 3 minutes.
- (3) Time interval is requisite between two items to prevent tiredness.

3.2. Weight Calculation. The joints are put in order by their importance after data processing. The higher it is graded, the higher it ranks and the more tired it becomes when human is in motion, which indicates its importance to human body. The sequencing results are listed in Table 1.

Kendall Coefficient of Concordance is used to judge the relevance of subjective judgment from the results. One has

$$W = \frac{S}{(1/12)K^2(N^3 - N)}, \quad (9)$$

where N is number of firefighters, K is number of firefighters who grade or standard number that grading depends on, and S is quadratic sum of dispersions between sum of scores R_i and averages of the sums.

Kendall coefficient of concordance calculation result $W = 0.8122$ shows high concordance between the 11 subjective

judgments according to “Kendall Coefficient of Concordance (W) Significance Critical Value Table.” The importance order is B shoulder > D hip > C elbow > F knee > E ankle. Based on this, analytic hierarchy process is used to calculate weight. This method needs to collect the opinions of experts, and in this experiment, the results are shown in Table 2 after integration and comparison of the results in the set. The judgment matrix is established according to the D value of R_i . One has

$$E = \begin{bmatrix} 1 & e_{12} & \cdots & e_{1n} \\ e_{21} & 1 & \cdots & e_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ e_{n1} & e_{n2} & \cdots & 1 \end{bmatrix}, \quad (10)$$

$$w_i = \sqrt[n]{\prod_{j=1}^n e_{ij}}. \quad (11)$$

The weight is obtained after unification. Similarly, the same method is used when calculating the weight of each joint, and the results are shown in Table 3.

4. Firefighting Operation Motion Moment Acquisition

4.1. Method Design. Software JACK is used to acquire the actual movement moment and joint motion angle. JACK is a mature, cross-platform environment for building, running, and integrating commercial-grade multiagent systems, which is built on a sound logical foundation. In JACK, agents are defined in terms of their beliefs, their desires, and their intentions. It is a set of long-term goals as well as an ever-evolving collection of thousands of lines of code and is used for human modeling and simulation in this research.

Through the angle simulation result obtained from the calculation of motion experiment by keyframe in JACK, the actual human body model moment is obtained [10]. The whole procedure is divided into three parts, data investigation of actual space, task simulation of virtual space, and quantitative output of simulation results. The implementation process is as Figure 3.

TABLE 1: Subjective evaluation results.

$N = 5$	Firefighters $K = 11$											R_i
	1	2	3	4	5	6	7	8	9	10	11

TABLE 2: Factor importance judgment value.

x, y comparison	$f y(x)$	$f x(y)$	Illustration
x and y "same importance"	1	1	x, y contribute the same to some property
x "bit more important"	3	1/3	x contributes a bit more
x "bit much more important"	5	1/5	x contributes a bit much more
x "much more important"	7	1/7	x contributes much ore
x "absolutely more important"	9	1/9	x contributes absolutely more important
x, y between two judgments	2, 4, 6, 8	1/2, 1/4, 1/6, 1/8	Compromise between two judgments

4.2. Joint Movement Angle Acquisition by Capture Experiment. Movement capture system begins from image analysis method, which utilizes humans or other objects similar to animation model to show the movements to be analyzed in a three-dimensional space, and then the computer captures the movement data and quantitatively analyzes the motion track by dealing with the motion sequence. This laboratory is equipped with eight cameras to capture movements, and the location distribution is shown in Figure 4. To guarantee a fine reflection effect, a piece of blue cloth is laid in the center of the room.

During the process of movement capture, two firefighters of identical height are selected to conduct the experiment based on the investigation on firefighter human dimension. The information of the experimenters and the equipment is listed in Table 4.

11 key points are marked on the body according to the establishment of firefighter mathematical model. Taking into consideration that the human body coordinate system should be established during the movement capture process and the shelter effect of movement to the markers, the markers are selected as in Figure 5.

Through previous task analysis on investigation, four typical movements are extracted among different firefighting motions. 14 training samples are covered in the four movements. The motion track coordinate is established based on motion capture, shown in Table 5.

According to the analysis above, the coordinate of human body markers and the trajectory diagram are obtained. The calculation of motion angle is divided into two types: projection angle and absolute angle. For a joint with one degree of freedom, absolute angle is suitable; and for a joint with more degrees of freedom, projection angle is used.

The condition in which people stand with two arms up-right down is treated as the initial movement and the joints

are regarded as vectors. According to the vector formula, $\vec{a} \cdot \vec{b} = |\vec{a}||\vec{b}|\cos\theta$, the movement range and angles are calculated. The joint angle takes the initial condition as benchmark, so the bending angle of single degree of freedom is $180^\circ - \theta$.

Taking water hose on high, for example, the angles of joints in this kind of motion are calculated as in Figure 6. Since this kind of motion mainly relates to shoulder joint and elbow joint with separately one degree of freedom and three degrees, the calculation results are shown in Figures 7 and 8.

Similarly, the joint angles change in different motions can be calculated through motion trail. The angle not only provides foundation for the following motion simulation, but also the joint movement maximum moment can be calculated through NASA power model; besides, it can provide data foundation for firefighting product design, such as clothing and equipment.

4.3. Firefighter Typical Movement Simulation. The ergonomic software JACK is used for simulation. The firefighting operation motion is simulated through key frame, which is utilized to be adjusted manually to change the motion of the virtual human. Ten key frames are chosen to simulate the joint angle, in order to acquire the moments in different time. Taking the motion of the disengaging water hose on high, for example, the motion simulation is shown in Figure 9. The joint moment output is illustrated in Table 6.

5. Fuzzy Judgment Result Analysis

The comfort membership is calculated in Matlab according to fuzzy comfort evaluation method. Taking the disengaging water hose on high at one moment, for example, the

FIGURE 6: Left and right elbow angles change with time.

first-order comprehensive fuzzy evaluation is conducted firstly. The factor set $U_{11} = \{U_{111}, U_{112}, U_{113}\} = \{\text{Upper arm stretch and striction, upper arm flexion and extension, upper arm rotation}\}$, $U_{12} = \{U_{121}\} = \{\text{Front arm flexion and extension}\}$ is calculated the membership $r_{ij} = (r_{i1}, r_{i2}, r_{i3})$ ($j = 1, 2, 3$) of this motion is determined, and then the evaluation matrix is obtained.

Shoulder factor judgment matrix is as follows:

$$R_{1\text{Left}} = \begin{bmatrix} 0 & 0 & 1 \\ 0 & 0.755 & 0.245 \\ 0.231 & 0.769 & 0 \end{bmatrix}, \quad (12)$$

$$R_{1\text{Right}} = \begin{bmatrix} 0 & 0 & 1 \\ 0.392 & 0.608 & 0 \\ 0.874 & 0.126 & 0 \end{bmatrix}.$$

Elbow factor judgment matrix is as follows:

$$R_{2\text{Left}} = [1 \ 0 \ 0], \quad R_{2\text{Right}} = [0 \ 0.717 \ 0.283]. \quad (13)$$

According to Equation $B = wR$:

$$B_{1\text{Left}} = [0.139 \ 0.344 \ 0.518],$$

$$B_{1\text{Right}} = [0.278 \ 0.259 \ 0.463], \quad (14)$$

$$B_{2\text{Left}} = [1 \ 0 \ 0],$$

$$B_{2\text{Right}} = [0 \ 0.717 \ 0.283].$$

Second-order comprehensive fuzzy evaluation: taking B as the evaluation matrix R of the second-order comprehensive fuzzy evaluation, and through weight calculation $B = wR$, the comprehensive fuzzy evaluation is obtained as follows:

$$B_{\text{UpperLimbs}} = [0.330 \ 0.325 \ 0.345]. \quad (15)$$

The comfort of some continuous motion is evaluated by the relationship of joint comfort change with time by Matlab. The membership of motion to comfort level is shown in Figures 10 and 11.

This motion involves two shoulders and two elbows and eight degrees of freedom, which forms the evaluation on upper limb movement. Through the previous weight calculation and proper unification, the comprehensive comfort level is evaluated.

From Figures 10, 11, and 12, the average of comprehensive comfort level in the latter half is higher than in

(a) X Stretch and striction

(a) X Stretch and striction

(b) Y Flexion and extension

(b) Y Flexion and extension

FIGURE 8: Right shoulder angle in direction X, Y, and Z change with time.

the former half. Since this motion is of cyclicity, so the joint angle in the latter half fits comfort level effect better. Therefore, the latter half is always selected to conduct the experiment. According to this motion, the improvement in comfort means the improvement of work efficiency and safety. At the same time, when many experimenters take part, the best-comfortable motions will be taken as the model samples through comprehensive comfort evaluation.

6. Conclusion

This paper conducts ergonomic evaluation on firefighting operation motions with the method of fuzzy evaluation, which provides evaluation foundation on firefighting operation improvement and the establishment of standard motion database. The main contribution of the paper includes the following ways

FIGURE 9: Motion simulation of disengaging water hose on high and moment result output.

FIGURE 10: Left shoulder comfort change with time.

FIGURE 11: Right shoulder comfort change with time.

FIGURE 12: Upper limbs comfort change with time.

- (1) The comprehensive fuzzy evaluation model of fire-fighting operation motion comfort level is established, which then is applied in the comfort evaluation.
- (2) Joint weight determination through investigation experiments.
- (3) The joint angles in every degree of freedom of typical motions are calculated in Matlab through the fire-fighter motion trails acquired by the motion capture equipment, which provide foundation to design fire-fighting equipment and clothing.
- (4) The joint motion moment is acquired through motion simulation of disengaging water hose in JACK, and then the comprehensive fuzzy evaluation of comfort is conducted. The membership of joints to comfort level is obtained too.

This paper used the method of objective skeleton motion ergonomic evaluation, thus the results are objective and reliable. The research ideas will be applied in the future work to complete the database of motion evaluation, and the evaluation results will be dealt with statistically to build standard evaluation system.
