1. Introduction

All graphs considered in this paper are finite, simple, undirected, and connected. For graph theoretic terminology, we refer to Harary [1].

The concept of open distance-pattern and open distance-pattern uniform graphs was studied in [2]. Given an arbitrary nonempty subset $M$ of vertices in a graph $G = (V, E)$, the open distance-pattern of a vertex $u$ in $G$ is defined to be the set $f^o_M(u) = \{d(u, v) : v \in M, u \neq v\}$, where $d(x, y)$ denotes the distance between the vertices $x$ and $y$ in $G$. If there exists a nonempty set $M \subseteq V(G)$ such that $f^o_M(u)$ is independent of the choice of $u$, then $G$ is called open distance-pattern uniform (odpu-) graph, and the set $M$ is called an open distance-pattern uniform (odpu-) set. The minimum cardinality of an odpu-set in $G$, if it exists, is the odpu-number of $G$ and is denoted by od(G). In this paper, we characterize several classes of odpu graph such as odpu-chordal graphs, interval graphs, split graphs, strongly chordal graphs, maximal outerplanar graphs, ptolemaic graphs, self-complementary graphs, odpu-distance-hereditary graphs, and odpu-cographs. We prove that the odpu-number of cographs is even and establish that any graph can be embedded into a self-complementary odpu-graph $H$, such that $G$ and $\overline{G}$ are induced subgraphs of $H$. We also prove that the odpu-number of a maximal outerplanar graph is either 2 or 5.

For a vertex $v$ in a connected graph $G$, the eccentricity $e(v)$ of $v$ is the distance to a vertex farthest from $v$. The minimum eccentricity among the vertices of a connected graph $G$ is the radius of $G$, denoted by $r(G)$, and the maximum eccentricity is its diameter, $d(G)$. A vertex $v$ in a connected graph $G$ is called a central vertex if $e(v) = r(G)$. The collection of all central vertices is called the center of $G$ denoted by $Z(G)$.

In paper [2], it is proved that a graph $G$ with radius $r(G)$ is an odpu graph if and only if the open distance-pattern of any vertex $u$ in $G$ is $f^o_M(u) = \{1, 2, \ldots, r(G)\}$, and a graph is an odpu-graph if and only if its centre $Z(G)$ is an odpu-set, thereby characterizing odpu-graphs, which in fact suggests an easy method to check the existence of an odpu-set for a given graph. The central subgraph $(Z(G))$ of a graph is the subgraph induced by the center.

Proposition 1 (see [2]). For any graph $G$, $\text{od}(G) = 2$ if and only if there exist at least two vertices $x, y \in V(G)$ such that $\text{deg}(x) = \text{deg}(y) = |V(G)| - 1$, where $\text{deg}(x)$ denote the degree of the vertex $x$ in $G$.

Proposition 2 (see [2]). There is no graph having odpu-number three.

Proposition 3 (see [2]). A graph $G$ is an odpu graph if and only if its centre $Z(G)$ is an odpu set, and hence $|Z(G)| \geq 2$.

Proposition 4 (see [2]). All self-centered graphs are odpu graphs.

Theorem 5 (see [2]). The shadow graph of any complete graph \( K_n \), \( n \geq 3 \) is an odpu-graph with odpu-number \( n + 2 \) (the shadow graph \( S(G) \) of a graph \( G \) is obtained from \( G \) by adding for each vertex \( v \) of \( G \) a new vertex \( v' \), called the shadow vertex of \( v \), and joining \( v' \) to all the neighbors of \( v \) in \( G \)).

Theorem 6 (see [2]). Every odpu-graph \( G \) satisfies \( r(G) \leq d(G) \leq r(G) + 1 \), where \( r(G) \) and \( d(G) \) denote the radius and diameter of \( G \), respectively.

The complement \( \overline{G} \) of a graph \( G \) has the same vertices as \( G \), and every pair of vertices are joined by an edge in \( \overline{G} \) if and only if they are not joined in \( G \). A self-complementary graph \( G \) is one that is isomorphic to its complement \( \overline{G} \).

Proposition 7 (see [3]). Let \( G \) be a nontrivial self-complementary graph. Then

(i) \( G \) has radius 2 and diameter 2 or 3,

(ii) \( G \) has diameter 3 if and only if it contains a dominating edge (an edge \( e \) in \( G \) is said to be a dominating edge if every edge in \( G \setminus \{e\} \) is adjacent to \( e \)),

(iii) the number of vertices of eccentricity 3 is never greater than the number of vertices of eccentricity 2.

Cographs (or complement reducible graphs) are defined as the class of graphs formed from a single vertex under the closure of the operations of union and complement. Cographs have the following two remarkable properties. Firstly, they are exactly the \( P_4 \)-restricted graphs, and secondly, a cograph has a unique tree representation, called a cotree.

Theorem 8 (see [4]). A graph \( G \) has a cotree if and only if \( G \) is a cograph. In that case, the cotree representation is unique.

A graph \( G \) is said to be chordal if every cycle of length at least 4 has a chord, that is, an edge joining nonconsecutive vertices of the cycle. A subset \( S \subseteq V(G) \) is called a vertex separator of \( G \) for nonadjacent vertices \( a \) and \( b \) (or \( a - b \) separator of \( G \)) if, in \( G - S \) (the graph obtained from \( G \) by the removal of the vertices of \( S \) and incident edges), the vertices \( a \) and \( b \) belong to distinct connected components. Let \( S(a, b, G) \) be the set of all \( a - b \) separators of \( G \). If no proper subset of \( S \subseteq S(a, b, G) \) belongs to \( S(a, b, G) \), then \( S \) is called a minimal \( a - b \) separator of \( G \). Let \( S_0(a, b, G) \) be the set of all minimal \( a - b \) separators of \( G \). The following propositions (cf. [8]) are needed in proving our main results.

Proposition 9 (see [8]). If \( G \) is a chordal graph and \( x, y \) are distinct nonadjacent vertices in \( (Z(G)) \), the central subgraph of \( G \), and \( S_0 \subseteq S_0(x, y, G) \), then the following conditions hold:

1. \( S_0 \subseteq Z(G) \),
2. there are at least two distinct vertices \( z_1, z_2 \in S_0 \) such that for every \( i = 1, 2 \) either \( d_G(z_i, x) = 1 \) or \( d_G(z_i, y) = 1 \). In particular, \( |S_0| \geq 2 \).

Proposition 10 (see [8]). If \( G \) is a chordal graph and \( x, y \) are distinct nonadjacent vertices in \( (Z(G)) \), the central subgraph of \( G \), then \( S_0(x, y, G) = S_0(x, y, (Z(G))) \).

Proposition 11 (see [8]). If \( G \) is a chordal graph, then \( (Z(G)) \) is connected.

Proposition 12 (see [8]). If \( G \) is a chordal graph, then \( d((Z(G))) \leq 3 \).

Proposition 13 (see [8]). If \( G \) is a chordal graph with \( (r, d) = (2, 3) \), then \( d((Z(G))) \leq 2 \).

Proposition 14 (see [8]). There are no self-centered chordal graph \( G \) with \( (r, d) = (3, 3) \). Consequently, for a self-centered chordal graph \( G \), \( r(G) \leq 2 \).

A distance-hereditary graph (cf. [9]) is a connected graph, which preserves the distance function for induced subgraphs. That is, the distance between any two nonadjacent vertices of any connected induced subgraph of such a graph is the same as the distance between these two vertices in the original graph.

Proposition 15 (see [9]). Let \( G \) be a distance-hereditary graph, and let \( u \) be a vertex of \( G \). Then, for each positive integer \( k \leq \max d(u, v) : v \in V \) and vertices \( v, w \) of the same connected component of \( N_k(u) \), one has \( N(w) \cup N_{k-1}(u) = N(w) \cup N_{k-1}(u) \), where the \( i \)-th neighborhood of the vertex \( u \), \( N_i(u) = \{v : d(u, v) = i\} \).

A graph \( G \) is an interval graph if and only if there is a one-to-one correspondence between its vertices and a set of intervals on the real line, such that two vertices are adjacent if and only if the corresponding intervals have an intersection. It is also well known that a graph \( G \) is an interval graph if and only if \( G \) is chordal and asteroidal triple-free, where asteroidal triple is a set of three distinct vertices \( \{v_1, v_2, v_3\} \) such that there exists a path connecting \( v_1 \) and \( v_j \) that contains no neighbor of \( v_k \) \((i \neq k \neq j)\), for every combination of \( 1 \leq i, j, k \leq 3 \) (cf. [10]).
A graph is a split graph if and only if its vertices can be partitioned into an independent set, and vertices which induces a clique. For simplicity, given a split graph $G$, we call a vertex partition of $V(G) = (V_I, V_C)$, such that $V_I$ is an independent set and vertices in $V_C$ induce a clique, as an I-C-decomposition of $G$. It is known that a chordal graph whose complement is also a chordal graph is equivalent to a split graph (cf. [10]).

A graph $G$ is strongly chordal if and only if it is possible to embed any graph $G$ into a plane with all nodes in the exterior boundary. It is called maximal outerplanar if no edge can be added without destroying its outerplanar property. Every maximal outerplanar graphs is chordal (cf. [12]).

Proposition 16 (see [12]). If $G$ is a maximal outerplanar graph, then its central subgraph $(Z(G))$ is isomorphic to one of the seven graphs in Figure 1.

2. Main Results

The following theorem gives a complete characterization for the odpu-self-complementary graphs. Further, given any positive even integer $n \geq 2$, there exists an odpu, self-complementary graphs with odpu-number $n$. Also, we prove that it is possible to embed any graph $G$ into a self-complementary, odpu-graph $H$ with $G$ and $\overline{G}$ being induced subgraphs of the graph $H$. Recall that a universal vertex means a vertex which is adjacent to all other vertices of the graph.

Theorem 17. A self-complementary graph $G$ is an odpu graph if and only if $G$ has no universal vertex in $(Z(G))$.

Proof. Assume that $G$ is a self-complementary, odpu-graph. If $v$ is a universal vertex in $(Z(G))$, then $f^o_M(v) = 1$, where $M = Z(G)$. Hence, all the vertices of $G$ must be adjacent to $v$ in $G$. Hence, $v$ is an isolated vertex in $\overline{G}$, a contradiction to the hypothesis that $G$ is a self-complementary graph.

Conversely, let the self-complementary graph $G$ be without universal vertex in $(Z(G))$. By Proposition 7, the possible radius $r$ and diameter $d$ of $G$ are $r = d = 2$ or $r = 2$ and $d = 3$. If $r = d = 2$, then the graph $G$ is self-centered, and hence it is an odpu-graph.

If $r = 2$ and $d = 3$, then by Proposition 7, $G$ has a dominating edge $uv$. In this case, the end points of the dominating edge lie in the centre, and any vertex outside the centre is adjacent to exactly one end vertex of any dominating edge.

Let $x$ be any arbitrary vertex in $Z(G)$. By hypothesis, $x$ is not a universal vertex, and hence, there exists a vertex $y \in Z(G)$ such that $d(x, y) = 2$. Therefore, $2 \in f^o_M(x)$. Also since $x$ is adjacent to a dominating edge, $1 \in f^o_M(x)$. Hence, $f^o_M(x) = \{1, 2\}$ for all $x \in Z(G)$.

Now, let $v$ be an arbitrary vertex in $G - Z(G)$. Then, $v$ is adjacent to exactly one vertex of a dominating edge $xy$. Hence, either $d(x, v) = 1$ and $d(y, v) = 2$ or $d(x, v) = 2$ and $d(y, v) = 1$. In both cases, $f^o_M(v) = \{1, 2\}$ for all $v \in V(G) - Z(G)$, and hence $G$ is an odpu-graph.

By Theorem 17 and Proposition 7, the following Corollary holds immediately.

Corollary 18. A self-complementary graph $G$ is an odpu-graph if and only if $r(G) = r((Z(G)) = 2$.

Theorem 19. Given any even integer $k \geq 4$, there exists a self-complementary, odpu-graph with odpu-number $k$.

Proof. First, we take a path $P_4$ and replace the end vertices of the path $P_4$ by copies of $n P_2$, and the interior vertices by copies of the complete $n$-partite graph $K_{4 \times 2, n \geq 2}$. Where two vertices of $P_4$ were joined by an edge, the corresponding graphs are now joined by all possible edges between them. Let the resulting graph be $G_1$. Clearly, $G_1$ is a self-complementary graph of $8n$ vertices with diameter 3. Moreover, if we add a $K_2$ and join it to all the vertices of the copies of $K_{4 \times 2, n \geq 2}$, we get a self-complementary graph $G_2$ of order $8n + 2$ and diameter 3 (see Figure 2).

Now, we claim that the odpu-number of $G_1$ is $4n$ and that of $G_2$ is $4n + 2$. Since the eccentricities of the vertices in $K_{4 \times 2, n \geq 2}$ are 2 and the eccentricities of the vertices of $n P_2$ are 3 in $G_1$, the center $Z(G_1)$ is the collection of all vertices of both...
Suppose that the given graph is of radius 1. Then, the construction given in Theorem 20 gives that \(|Z(H)| = 2\) for all \(u \in Z(H)\). Also, there exist at least two leaves \(u \in Z(H)\) and \(v \in Z(H)\) such that \(d(u, v) = 2\). Hence, \(f_M^o(u) = \{1, 2\}\) for all \(u \in Z(H)\). Therefore, \(H\) is an odpu-graph.

Remark 21. Suppose that the given graph is of radius 1. Then, the construction given in Theorem 20 gives that \(\langle Z(H) \rangle = 2\) for all \(u \in Z(H)\). Also, there exist at least two leaves \(u \in Z(H)\) and \(v \in Z(H)\) such that \(d(u, v) = 2\). Hence, \(f_M^o(u) = \{1, 2\}\) for all \(u \in Z(H)\). Therefore, \(H\) is an odpu-graph.

Corollary 24. A cograph \(G\) is an odpu-graph if and only if \(r(G) = r(\langle Z(G) \rangle)\).

Theorem 25. The odpu-number of an odpu-cograph is always even.

Proof. By Theorem 8, each cograph is uniquely represented as a cotree and conversely. Hence, we prove the theorem using cotree characterization of cographs. Consider the cotree \(T\) of the odpu-cograph \(G\). Since the odpu-graphs are connected, the root which is labeled by (1) in the cotree has at least two children.

If the root (1) has a child which is a leaf in the cotree, then this leaf vertex \(u\) is adjacent to all vertices of the cograph \(G\). Hence, \(u\) is a universal vertex in \(G\), and hence, \(r(G) = 1\). Since \(G\) is an odpu-cograph, \(|Z(G)| \geq 2\), and hence, there exist two universal vertices in \(G\). Hence, there exist at least two leaves attached to the root (1) of the cotree \(T\). Hence, in this case \(od(G) = 2\).

So assume that \(G\) does not have a universal vertex. Thus, there is no leaf attached to the root (1), and hence, \(r(G) = 2\). Since \(G\) is connected and all children of the root (1) are labeled by (0), the root (1) has at least two children which are labeled by (0). Let the root (1) have \(k\) children, namely, \(R_1, R_2, \ldots, R_k\), which are labeled by (0). Let \(M\) be the minimal odpu-set of \(G\). Since \(r(G) = 2\), \(f_M^o(u) = \{1, 2\}\) for all \(u \in V(G)\). Also, for a cotree, each node \(R_i\) labeled by (0) at least has two leaves \(x\) and \(y\) descending from that node which are nonadjacent. Also, each leaf \(u\) descending from the node \(R_i\) is adjacent to all the leaves descending from \(R_j, j \neq i\), hence, leaves \(x\) and \(y\) with \(d(x, y) = 2\) only when \(x\) and \(y\) are descending from same \(R_i\).

So, there exist at least two vertices \(x\) and \(y\) descending from \(G_1, G_2\). Since \(\langle Z(G) \rangle = 2\) for all \(u \in Z(H)\), there exist at least two leaves \(u \in Z(H)\) and \(v \in Z(H)\) such that \(d(u, v) = 2\). Hence, \(f_M^o(u) = \{1, 2\}\) for all \(u \in Z(H)\). Therefore, \(H\) is an odpu-graph.

Theorem 22. Any graph \(G\) can be embedded into a self-complementary, odpu-graph \(H\) with \(G\) and \(\overline{G}\) being induced subgraphs of \(H\).

The following result gives the characterization for odpu-cographs and proves that the odpu-number of an odpu-cograph is always even.

Theorem 23. A cograph \((P_4\text{-free graph}) G\) is an odpu-graph if and only if \(|Z(G)| \geq 2\).

Proof. Let \(G\) be a \(P_4\)-free odpu-graph. Then, clearly \(|Z(G)| \geq 2\).

Conversely, let \(G\) be a cograph with \(|Z(G)| \geq 2\). Since the diameter of a cograph is less than or equal to 2, the following are the only three possibilities. If (i) \(r(G) = d(G) = 1\) or (ii) \(r(G) = d(G) = 2\), then \(G\) is self-centered, and hence, it is an odpu-graph. If (iii) \(r(G) = 1\) and \(d(G) = 2\), then by assumption \(|Z(G)| \geq 2\), there exist at least two universal vertices \(u\) and \(v\) in \(G\). Therefore, \(\{u, v\}\) forms an odpu-set of \(G\), hence the theorem.

Theorem 17, \(G_1\) is an odpu-graph. Let \(M\) be a minimal odpu-set of \(G_1\). For any vertex \(v \in Z(G_1)\), there is exactly one vertex \(v \in Z(G_1)\) such that \(d(u, v) = 2\). Hence, all the vertices of \(Z(G_1)\) must be in \(M\). Hence, \(od(G_1) = 4n\).

Now, consider \(G_2\). By the same argument above, all the vertices of \(Z(G_2)\) must be in the minimal odpu-set \(M\). Hence, the odpu-number of \(G_2\) is \(4n + 2\), hence, the theorem.

**Theorem 20.** Any graph \(G\) with \(r(G) \geq 2\) can be embedded into a self-complementary, odpu-graph \(H\) with both \(G\) and \(\overline{G}\) as induced subgraphs of \(H\).

**Proof.** We construct the graph \(H\) as follows. First, consider a path \(P_4\), and replace the end vertices of the path \(P_4\) by copies of \(G\) and the interior vertices by copies of \(G\). Whenever two vertices of \(P_4\) were joined by an edge, the corresponding graphs are joined by all possible edges between them so that we get a complete bipartite graph between the vertices of the corresponding graphs. Then, the resulting graph \(H\) is self-complementary with \(G\) (and \(\overline{G}\)) as induced subgraph of \(H\) with \(r(H) = 2\) and \(d(H) = 3\). Also, all the vertices of \(G\) belong to the centre \(Z(H)\), and the vertices of \(\overline{G}\) belong to \(H - Z(H)\). Let \(M = Z(H)\).

Let \(u \in Z(H)\). Since \(r(G) \geq 2\), there exists a vertex \(v\) not adjacent to \(u\) in the same copy of \(G\). But there exists a path \((u\cdots v)\) in \(H\), where \(w\) is in \(G\), for which \(u, v\) do not belong. Hence, \(d_H(u, v) = 2\), and therefore, \(2 \in f_M^o(u)\). Since \(xy \in E(H)\) for \(X \in V(G_1)\) and \(y \in V(G_2)\), \(1 \in f_M^o(u)\). Hence, \(f_M^o(u) = \{1, 2\}\) for all \(u \in Z(H)\).

Let \(u \in V(G) - Z(G)\). Then, \(u\) is adjacent to a vertex \(w \in Z(H)\). Therefore, \(1 \in f_M^o(u)\). Also by construction, there exists a vertex \(v \in M\) such that \(d(u, v) = 2\). Hence, \(2 \in f_M^o(u)\). Hence, \(f_M^o(x) = \{1, 2\}\) for all \(x \in V(H)\). Hence, \(H\) is an odpu-graph.
each $R_i$ ($1 \leq i \leq k$) and belonging to the minimal odpu-set $M$. Hence, $|M| \geq 2k$.

Now, we prove that $M$ has exactly $2k$ elements. Let $M$ be the set of $2k$ leaves such that the exactly two leaves $x$ and $y$ are descending from the same node $R_i$ ($1 \leq i \leq k$) with $xy \notin E(G)$. Let $x \in V(G)$. Then, there exists a $y \in M$ which is descending from the same node $R_i$, where the leaf $x$ belongs, such that $xy \notin E(G)$. Hence, $d(x, y) = 2$, and hence, $2 \in f_M'(x)$. Since $x$ is adjacent to all vertices in $M$ which are descending from the nodes $R_i$, for all $j \neq i, 1 \in f_M'(x)$. Hence, $f_M'(x) = \{1, 2\}$ for all $x \in V(G)$. Hence, $od(G) = 2k$.

**Remark 26.** Given any positive even integer $2n$, the complete $n$-partite graphs $K_{2,2,...,2}$ are odpu-cographs with odpu-number $2n$.

Next, we establish the characterization for odpu-chordal graphs.

**Theorem 27.** A chordal graph $G$ is an odpu-graph if and only if $r(G) = r(\langle Z(G) \rangle)$.

**Proof.** Let $G$ be a chordal graph with $r(G) = r(\langle Z(G) \rangle)$. Since $r(\langle Z(G) \rangle) \leq 2$, there are two possibilities:

(i) $r(G) = r(\langle Z(G) \rangle) = 1$. Then, there are two universal vertices in $G$, and hence by Proposition 1, $G$ is an odpu-graph.

(ii) $r(G) = r(\langle Z(G) \rangle) = 2$. By Proposition 10, $d_{\langle Z(G) \rangle}(u, v) = d_{\langle Z(G) \rangle}(u, v)$ for all $u, v \in Z(G)$. Let $u \in Z(G)$. Since $r(\langle Z(G) \rangle) = 2$, there exists a vertex $v \in Z(G)$ such that $d(u, v) = 2$. Hence, $2 \in f_M'(u)$ for all $u \in Z(G)$. Now, the connectedness of $\langle Z(G) \rangle$ ensures the existence of a vertex $w \in Z(G)$ such that $d(u, w) = 1$. Therefore, $f_M'(u) = \{1, 2\}$ for all $u \in Z(G)$. Now, let $u \in V(G) \setminus Z(G)$.

Conversely, assume that $G$ is a chordal-odpu-graph. Since $r(G) \leq 2$ and $\langle Z(G) \rangle$ are connected, $r(\langle Z(G) \rangle) \leq 2$.

If $r(\langle Z(G) \rangle) = 1$, then $f_M'(u) = \{1\}$ for all $u \in V(G)$. Thus, there exist at least two universal vertices in $G$. Hence, $r(G) = 1$.

If $r(\langle Z(G) \rangle) = 2$, $f_M'(u) = \{1, 2\}$ for all $u \in V(G)$. Since $Z(G)$ is an odpu-set, the distance from any vertex of $G$ to any vertex of $Z(G)$ is less than or equal to 2. Thus, $r(G) = 2$, and hence, $r(G) = r(\langle Z(G) \rangle)$.

**Corollary 28.** A chordal graph $G$ is an odpu-graph, and then $\langle Z(G) \rangle$ is self-centered.

**Proof.** Let $G$ be chordal, odpu-graphs. If $\langle Z(G) \rangle$ is not self-centered, then $r(\langle Z(G) \rangle) \neq d(\langle Z(G) \rangle)$. Hence, there exist vertices $u, v \in Z(G)$ such that $e_{\langle Z(G) \rangle}(u) \neq e_{\langle Z(G) \rangle}(v)$. Let $e_{\langle Z(G) \rangle}(u) = d(\langle Z(G) \rangle), e_{\langle Z(G) \rangle}(v) = r(\langle Z(G) \rangle)$, and $M = Z(G)$. Since $d_{\langle Z(G) \rangle}(u, v) = d_{\langle Z(G) \rangle}(u, v)$ for all $u, v \in Z(G)$, $f_M'(u)$ has an element $d(\langle Z(G) \rangle)$, a contradiction.

**Remark 29.** The converse of Corollary 28 need not be true. For example, $P_4$ is chordal with $\langle Z(P_4) \rangle = P_2$, which is self-centered, but $P_4$ is not an odpu-graph.

Since interval graphs, split graphs, block graphs, ptolemaic graphs, strongly chordal graphs, and maximal outer-planar graphs are subclasses of chordal graphs, (cf. [10]), the following corollary is immediate from Theorem 27 and Corollary 28.

**Corollary 30.** The following classes of graphs $G$: interval graphs, split graphs, block graphs, ptolemaic graphs, strongly chordal graphs, or maximal outerplanar graphs are odpu-graphs if and only if $r(G) = r(\langle Z(G) \rangle)$, and hence, $\langle Z(G) \rangle$ is self-centered.

The following theorem establishes the characterization of odpu-distance-hereditary graphs. Further, we show that the central subgraph $\langle Z(G) \rangle$ of distance-hereditary-odpu-graph $G$ is either self-centered or disconnected.

**Theorem 31.** Let $G$ be a distance-hereditary graph with connected $\langle Z(G) \rangle$. Then, $G$ is an odpu-graph if and only if $r(G) = r(\langle Z(G) \rangle)$.

**Proof.** Let $G$ be a distance-hereditary graph with $\langle Z(G) \rangle$ which is connected. Let $G$ be an odpu-graph. If $r(G) \neq r(\langle Z(G) \rangle)$, then $r(\langle Z(G) \rangle) < r(G)$. Since $\langle Z(G) \rangle$ is connected, $d_{\langle Z(G) \rangle}(u, v) = d_{\langle Z(G) \rangle}(u, v)$ for all $u, v \in Z(G)$. But since $r(\langle Z(G) \rangle) < r(G)$, $G$ is not an odpu-graph, which is not possible. Hence, $r(G) = r(\langle Z(G) \rangle)$.

Conversely, let $r(G) = r(\langle Z(G) \rangle) = r$. Let $u \in Z(G)$. Then, there exists a vertex $v \in Z(G)$ such that $d(u, v) = r$. Since $\langle Z(G) \rangle$ is connected, $f_M'(u) = \{1, 2, \ldots, r\}$.

Now, let $u \in V(G) \setminus Z(G)$. If $u \notin f_M'(u)$, then $N_G(u) \subseteq Z(G)$, where $N_G(u) = \{v \in V(G) : d(u, v) = r\}$. Let $k$ be the largest integer such that $N_G(u) \cap Z(G) = \phi$, and let $w \in N_G(u) \cap Z(G)$. Then, since $d_G(u, w) = k$, $d_G(w) \geq k$. But since $u$, $N_G(u) \neq Z(G)$, by Proposition 15, $e_G(w) \leq k - 2$.
Thus, \( r(G) \neq r(\langle Z(G) \rangle) \), a contradiction. Therefore, \( 1 \in f_M^r(u) \) for all \( u \in V(G) - Z(G) \).

Now, if \( r \notin f_M^r(u) \), then \( N_r(u) \cap Z(G) = \phi \). Since \( u \notin Z(G) \), by Proposition 15, \( e_{\langle Z(G) \rangle}(w) \leq r - 1 \) for every \( w \in Z(G) \). Thus, \( r(\langle Z(G) \rangle) < r(G) \), a contradiction. Hence, \( r \in f_M^r(u) \).

Since \( 1 \in f_M^r(u) \), \( f_M^r(u) = \{1, 2, \ldots, r\} \) for every \( u \in V(G) - Z(G) \), hence the theorem. \( \Box \)

**Corollary 32.** For a distance-hereditary-odpu-graph \( G \), either \( \langle Z(G) \rangle \) is disconnected or it is self-centered.

**Proof.** Let \( G \) be a distance-hereditary-odpu-graph. If \( \langle Z(G) \rangle \) is connected, then we prove that \( (Z(G)) \) is self-centered. If not, let \( r(\langle Z(G) \rangle) \neq d(\langle Z(G) \rangle) \). Let \( u, v \in Z(G) \) such that \( e_{\langle Z(G) \rangle}(u) = r(\langle Z(G) \rangle) \) and \( e_{\langle Z(G) \rangle}(v) = d(\langle Z(G) \rangle) \). Since \( G \) is distance-hereditary, \( d_{\langle Z(G) \rangle}(x, y) \leq d_G(x, y) \) for all \( x, y \in Z(G) \). Thus, \( d(\langle Z(G) \rangle) \in f_M^r(v) \) and \( d(\langle Z(G) \rangle) \in f_M^r(u) \), which is a contradiction, hence the theorem. \( \Box \)

**Remark 33.** The converse of Corollary 32 need not be true. For example, \( P_4 \) is distance-hereditary and \( \langle Z(P_4) \rangle = P_2 \), which is self-centered, but \( P_4 \) is not an odpu-graph.

The following theorem gives a necessary condition for a maximal outerplanar graph to be an odpu-graph in terms of a specific structure of the central subgraph \( \langle Z(G) \rangle \).

**Theorem 34.** If \( G \) is a maximal outerplanar-odpu-graph, then its central subgraph \( \langle Z(G) \rangle \) is isomorphic to one of the graphs in Figure 3.

**Proof.** By Proposition 16, the central subgraph \( \langle Z(G) \rangle \) of a maximal outerplanar graph \( G \) is isomorphic to one of the seven graphs given in Figure 1.

Since every maximal outerplanar graph is chordal, by Corollary 28, the central subgraph \( \langle Z(G) \rangle \) is self-centered. Therefore, \( \langle Z(G) \rangle \) is isomorphic to one of the three graphs given in Figure 3, hence the theorem. \( \Box \)

**Theorem 35.** A maximal outerplanar graph \( G \) is an odpu-graph if and only if it is isomorphic to one of the graphs in Figure 4.

**Proof.** Let \( G \) be a maximal outerplanar-odpu-graph. By Theorem 34, \( \langle Z(G) \rangle \) is isomorphic to one of the graphs in Figure 3, and by Corollary 30, \( r(G) = r(\langle Z(G) \rangle) \). Thus, there are two cases: \( r(G) = r(\langle Z(G) \rangle) = 1 \) and \( r(G) = r(\langle Z(G) \rangle) = 2 \).

Case 1 \((r(G) = r(\langle Z(G) \rangle) = 1)\). By Proposition 1, there exist at least two universal vertices in \( G \), and hence, \( \langle Z(G) \rangle \) is isomorphic to either \( G_1 \) or \( G_2 \) in Figure 3. Consider all graphs \( G \) with two universal vertices. Then, \( G_3 \) is the least of them. Let \( G_3 \equiv H_1 \) be an edge \( uv \). Now, add vertices one by one to get a new maximal outerplanar graph \( G \) in such a way that \( u \) and \( v \) are universal in \( G \). That is, \( G = uv + \{v_1, v_2, \ldots, v_k\} \), where “+” denotes the operator join (The join of two graphs \( G_1 = (V_1, E_1) \) and \( G_2 = (V_2, E_2) \) denoted by \( G_1 + G_2 \) has the vertex set as \( V = V_1 \cup V_2 \) and the edge set \( E \) contains all the edges of \( G_1 \) and \( G_2 \) together with all edges joining the vertices of \( V_1 \) with the vertices of \( V_2 \) ), of two graphs. When \( i = 1 \), \( G = uv + v_1 \equiv H_2 \), which is a maximal outerplanar-odpu-graph. When \( i = 2 \), \( G = uv + \{v_1, v_2, \ldots, i\} \equiv H_3 \), which is also a maximal outerplanar-odpu-graph. When \( i \geq 3 \), \( G = uv + \{v_1, v_2, \ldots, i\} \equiv H_4 \), which is not maximal outerplanar graph. Thus, \( H_1, H_2, H_3 \) are the only maximal outerplanar graphs with \( r(G) = r(\langle Z(G) \rangle) = 1 \).

Case 2 \((r(G) = r(\langle Z(G) \rangle) = 2)\). By Theorem 34, the central subgraph is isomorphic to \( G_4 \equiv H_4 \) only. Since \( H_4 \) is self-centered, it is an odpu-graph. Suppose that there exists a maximal outerplanar-odpu-graph \( H \) other than \( H_4 \) with \( \langle Z(H) \rangle \equiv G_3 \). Then, there exists a vertex \( x \notin V(H) - Z(H) \) such that \( x \) is adjacent to a vertex of \( \langle Z(H) \rangle \equiv G_3 \), say the vertex \( a \). Since \( H \) is maximal outerplanar, \( x \) cannot be adjacent to any of the vertices \( b, c, \) and \( d \). If there exists a vertex \( w \) such that \( (xwa') \) is a path in the graph \( H \), then \( S(a, a', H) \notin Z(H) = G_3 \), a contradiction. Hence, \( d(x, a') = 3 \). Thus, \( e_{H}(a') \geq 3 \), and hence, \( a' \notin Z(H) \), a contradiction. Hence, there does not exist a vertex \( x \) other than the vertices of \( G_3 \). Hence, there is no maximal outerplanar-odpu-graph \( H \) other than \( H_4 \) with \( r(G) = r(\langle Z(G) \rangle) = 2 \).

**Theorem 36.** For a maximal outerplanar graph \( G \), the odpu-number is either 2 or 5.

**Proof.** By Theorem 25, the maximal outerplanar odpu-graphs are one of the graphs in Figure 4.

It is enough to prove that each of \( H_1, H_2, \) and \( H_3 \) has odpu-number 2. Next, the graph \( H_4 \) is self-centered with radius 2 and hence, \( f_M^r(u) = \{1, 2\} \) for all \( u \in V(H_4) \). Let \( M \) be a minimal odpu-set of \( H_4 \). Hence, \( a' \in V(H_4) \) is the only vertex at a distance of two from the vertex \( a \), and hence, \( a' \) must be in \( M \). Similarly \( b' \) and \( c' \) are the only vertices of \( H_4 \) at a distance of two from \( b \) and \( c \), respectively, and hence, \( b, c \in M \). Hence, \( |M| \geq 3 \). If \( M = \{a, b', c'\} \), then \( 1 \notin f_M^r(u) \), for \( u = a, b', c' \). Thus, without loss of generality, let \( M = \{a, a', b', c'\} \). Then, \( M = \{a, b', c'\} \). But \( 1 \notin f_M^r(a') \), and hence, at least one of the vertices \( b \) and \( c \) must be in \( M \). So let \( b \in M \). Then, \( M = \{a, b, a', b', c'\} \). Hence, \( f_M^r(u) = \{1, 2\} \) for all \( u \in V(H_4) \). Thus, \( od(H) = 5 \). Hence, the odpu-number of maximal outerplanar graph is either 2 or 5. \( \Box \)

**Theorem 37.** For every integer \( n \geq 2 \), there is an odpu-graph \( G \) of order \( n(n + 2) \) such that its central subgraph \( \langle Z(G) \rangle \) is disconnected.
Proof. Consider two disjoint complete graphs $G_1 = K_n$ and $G_2 = K_n$ of order $n$. Now, add all edges between these two complete graphs, and subdivide each of the new edges of the bipartite subgraph between $G_1$ and $G_2$ by one (a degree 2 vertex) to get a graph $G$ of order $n(n + 2)$. Let the vertices of $G_1 \{v_1, v_2, \ldots, v_n\}$, the vertices of $G_2 \{u_1, u_2, \ldots, u_n\}$, and $w_{i,j}$ the vertex which subdivides the earlier edge $v_i u_j$ of the bipartite graph. Then, all vertices $w_{i,j}$'s have eccentricity 3 in $G$, and the new graph has radius 2 and diameter 3. Also the central subgraph $(Z(G))$ is the disjoint union of the complete graphs $G_1$ and $G_2$. Hence, $(Z(G))$ is disconnected.

Now, we prove that $G$ is an odpu-graph. Let $M = Z(G) = \{V(G_1) \cup V(G_2)\}$. For each $v_i \in V(G_1)$, there exists a $v_j \in V(G_2)$ such that $d(v_i, v_j) = 1$, and hence, $1 \in f_{M}^o(v_i)$. Now, $d(v_i, u_j) = 2$, for all $u_j \in V(G_2)$, and hence, $2 \in f_{M}^o(v_i)$. Hence, $f_{M}^o(v_i) = \{1, 2\}$ for all $v_i \in V(G_1)$. Similarly, $f_{M}^o(u_j) = \{1, 2\}$ for all $u_j \in V(G_2)$. Now, each vertex $w_{i,j}$ is adjacent to exactly $v_i$ and $u_j$, and hence, $d(w_{i,j}, v_i) = 1$ and $d(w_{i,j}, u_j) = 1$. Hence, $1 \in f_{M}^o(w_{i,j})$ for all $i, j$. Since $d(w_{i,j}, v_k) = 2$, for all $i \neq k$ and $d(w_{i,j}, u_k) = 2$, for all $j \neq k$, $2 \in f_{M}^o(w_{i,j})$ for all $i, j$. Hence, $f_{M}^o(w_{i,j}) = \{1, 2\}$ for all $i, j$, and hence, $G$ is an odpu-graph. □

3. Conclusion

The characterization of odpu-graphs leads to an interesting condition $r(G) = r((Z(G)))$, for many important classes of graphs such as chordal graphs, interval graphs, split graphs, strongly chordal graphs, self-complementary graphs, $P_4$-free graphs, maximal outerplanar graphs, ptoloeic graphs, and distance-hereditary graphs. However, this characterization is not in general a characterization for all odpu-graphs. For example, by Theorem 37, there are classes of odpu-graphs with radius 2 and disconnected centre. That is, $r((Z(G)))$ = \infty. Thus, there are more classes of odpu-graphs which do not come under this characterization. We leave it for further scope of investigations.
