Abstract

The object of the present investigation is to solve the Fekete-Szegö problem and determine the sharp upper bound to the second Hankel determinant for a new class \(R(a,c)\) of analytic functions involving the Carlson-Shaffer operator in the unit disk. We also obtain a sufficient condition for normalized analytic functions in the unit disk to be in this class.

1. Introduction and Preliminaries

Let \(A\) be the class of functions \(f\) of the form

\[
f(z) = z + \sum_{k=2}^{\infty} a_k z^k\tag{1}
\]

which are analytic in the open unit disk \(U = \{z \in \mathbb{C} : |z| < 1\}\).

A function \(f \in A\) is said to be starlike of order \(\rho\), if

\[
\Re \left\{ \frac{zf'(z)}{f(z)} \right\} > \rho \quad (0 \leq \rho < 1; \ z \in U) . \tag{2}
\]

Similarly, a function \(f \in A\) is said to be convex of order \(\rho\), if

\[
\Re \left(1 + \frac{zf''(z)}{f'(z)} \right) > \rho \quad (0 \leq \rho < 1; \ z \in U) . \tag{3}
\]

By usual notations, we write these classes of functions by \(S^*(\rho)\) and \(K(\rho)\), respectively. We denote \(S^*(0) = S^*\) and \(K(0) = K\), the familiar subclasses of starlike, convex functions in \(U\).

Furthermore, let \(\mathcal{P}\) denote the class of analytic functions \(\phi\) normalized by

\[
\phi(z) = 1 + p_1 z + p_2 z^2 + \cdots \quad (z \in U) \tag{4}
\]

such that \(\Re(\phi(z)) > 0\) in \(U\).

For functions \(f\) and \(g\), analytic in \(U\), we say that \(f\) is subordinate to \(g\), written as \(f \prec g\) or \(f(z) < g(z)\) \((z \in U)\), if there exists a Schwarz function \(\omega\), which (by definition) is analytic in \(U\) with \(\omega(0) = 0\), \(|\omega(z)| < 1\), and \(f(z) = g(\omega(z))\), \(z \in U\). Furthermore, if the function \(g\) is univalent in \(U\), then we have the following equivalence relation (cf., e.g., [1]; see also [2]):

\[
f(z) < g(z) \iff f(0) = g(0), \quad f(U) \subset g(U) . \tag{5}
\]

For functions \(f_j(z) = \sum_{k=0}^{\infty} a_{k,j} z^k\) \((j = 1, 2)\) analytic in \(U\), we define the Hadamard product (or convolution) of \(f_1\) and \(f_2\) by

\[
(f_1 \ast f_2)(z) = \sum_{k=0}^{\infty} a_{k,1} a_{k,2} z^k = (f_1 * f_2)(z) \quad (z \in U) . \tag{6}
\]

Note that \((f_1 \ast f_2)\) is also analytic in \(U\).
Carlson and Shaffer [3] defined the linear operator $\mathcal{L}(a, c) : \mathcal{A} \rightarrow \mathcal{A}$ in terms of the incomplete beta function $\varphi$ by

$$\mathcal{L}(a, c) f(z) = \varphi(a, c; z) * f(z) \quad (f \in \mathcal{A}; z \in \mathcal{U}),$$  

where

$$\varphi(a, c; z) = \sum_{k=0}^{\infty} \frac{(a) \Gamma(z+k+1)}{\Gamma(a) \Gamma(k+1)} (a \in \mathbb{C}, \ c \in \mathbb{C} \setminus \mathbb{Z}_0, \ z_0 = \{\ldots, -2, -1, 0\}; \ z \in \mathcal{U})$$  

and $(\alpha)_n$ denotes the Pochhammer symbol (or shifted factorial) given, in terms of the Gamma function $\Gamma$, by

$$(\alpha)_n = \frac{\Gamma(\alpha+n)}{\Gamma(\alpha)}$$

$$= \begin{cases} \kappa(\alpha+1)(\alpha+2) \cdots (\alpha+n-1), & n \in \mathbb{N} \\ 1, & n = 0. \end{cases}$$

If $f \in \mathcal{A}$ is given by (I), then it follows from (7) that

$$\mathcal{L}(a, c) f(z) = z + \sum_{k=1}^{\infty} \frac{(a)_k}{(c)_k} a_{k+1} z^{k+1} \quad (z \in \mathcal{U}).$$

We note that for $f \in \mathcal{A}$

(i) $\mathcal{L}(a, a) f(z) = f(z)$;

(ii) $\mathcal{L}(2, 1) f(z) = z f'(z)$;

(iii) $\mathcal{L}(3, 1) f(z) = z f'(z) + (1/2) z^2 f''(z)$;

(iv) $\mathcal{L}(m+1, 1) f(z) = \mathcal{D}^m f(z) = (z/(1-z)^{m+1}) * f(z) \quad (m \in \mathbb{Z}, m > -1), \quad \text{the well-known Ruscheweyh differential derivative} \ [4] \ \text{of} \ f$;

(v) $\mathcal{L}(2, 2 - \mu) f(z) = \Omega_{\mu} f(z) \quad (0 \leq \mu < 1; \ z \in \mathcal{U}), \quad \text{the well-known Owa-Srivastava fractional differential operator} \ [5]$. We also observe that $\Omega_{\mu} f(z) = f(z)$ and

$$\Omega_{\mu} f(z) = \lim_{\mu \to 0} \Omega_{1/\mu} f(z) = z f'(z).$$

With the aid of the linear operator $\mathcal{L}(a, c)$, we introduce a subclass of $\mathcal{A}$ as follows.

Definition 1. A function $f \in \mathcal{A}$ is said to be in the class $\mathcal{R}(a, c)$, if it satisfies the condition

$$\left\| \frac{\mathcal{L}(a, c) f(z)}{z} \right\|^2 < 1 \quad (z \in \mathcal{U}).$$

It follows from (12) and the definition of subordination that a function $f \in \mathcal{R}(a, c)$ satisfies the following subordination relation:

$$\frac{\mathcal{L}(a, c) f(z)}{z} < \frac{1}{\sqrt{1+z}} \quad (z \in \mathcal{U}).$$

We further note that if $f \in \mathcal{R}(a, c)$, then the function $\mathcal{L}(a, c) f(z)/z$ lies in the region bounded by the right half of the lemniscate of Bernoulli given by

$$\{w \in \mathbb{C} : |\omega^2 - 1| < 1\} = \{u + iv : (u^2 + v^2)^2 = 2(u^2 - v^2)\}.$$  

Noonan and Thomas [6] defined the $q$th Hankel determinant of a sequence $a_k, a_{k+1}, a_{k+2}, \ldots$ of real or complex numbers by

$$H_q(k) = \begin{vmatrix} a_k & a_{k+1} & \cdots & a_{k+q-1} \\ a_{k+1} & a_{k+2} & \cdots & a_{k+q} \\ \vdots & \vdots & \ddots & \vdots \\ a_{k+q-1} & a_{k+q} & \cdots & a_{k+2q-1} \end{vmatrix} \quad (k, q \in \mathbb{N}).$$

This determinant has been studied by several authors including Noor [7] with the subject of inquiry ranging from the rate of growth of $H_q(k)$ (as $k \to \infty$) to the determination of precise bounds with specific values of $k$ and $q$ for certain subclasses of analytic functions in the unit disc $\mathcal{U}$. For $k = 1, q = 2, a_1 = 1, a_2 = 2$, the Hankel determinant simplifies to

$$H_2(1) = |a_3 - a_2|^2, \quad H_2(2) = |a_4 - a_3|^2.$$  

The Hankel determinant $H_2(1)$ was considered by Fekete and Szegö [8] and we refer to $H_2(2)$ as the second Hankel determinant. It is known [9] that if $f$ given by (I) is analytic and univalent in $\mathcal{U}$, then the sharp inequality $H_2(1) = |a_3 - a_2|^2 \leq 1$ holds. For a family $\mathcal{F}$ of functions in $\mathcal{A}$ of the form (I), the more general problem of finding the sharp upper bounds for the functionals $|a_3 - \lambda a_2|^2$ ($\lambda \in \text{Cor} \lambda \in \mathbb{R}$) is popularly known as Fekete-Szegö problem for the class $\mathcal{F}$. The Fekete-Szegö problem for various known subclasses of univalent functions (i.e., starlike, convex, close-to-convex, etc.) has been completely settled [8, 10–12]. Recently, Janteng et al. [13, 14] have obtained the sharp upper bounds to the second Hankel determinant $H_2(2)$ for the family of functions in $\mathcal{A}$ whose derivatives have positive real part in $\mathcal{U}$. For initial work on this class of functions, one may refer to the work of MacGregor [15].

In our present investigation, we follow the techniques adopted by Libera and Złotkiewicz [16,17] to solve the Fekete-Szegö problem and also determine the sharp upper bound to the second Hankel determinant for the class $\mathcal{R}(a, c)$.

To establish our main results, we will need the following lemma for functions belonging to the class $\mathcal{R}$. 
Lemma 2. Let the function \( \phi \), given by (4), be a member of the class \( \mathcal{P} \). Then
\[
|p_k| \leq 2 \quad (k \geq 1), \quad (17)
\]
\[
|p_k - v p_k^2| \leq 2 \max\{1, |2v - 1|\} \quad (v \in \mathbb{C}), \quad (18)
\]
\[
p_2 = \frac{1}{2} \left\{ p_1^2 + (4 - p_1^2) x \right\},
\]
\[
p_3 = \frac{1}{4} \left\{ p_1^3 + 2 \left( 4 - p_1^2 \right) p_1 x
\]
\[- (4 - p_1^2) p_1 x^2 + 2 \left( 4 - p_1^2 \right) (1 - |x|^2) z \right\},
\] for some complex numbers \( x, z \) satisfying \(|x| \leq 1\) and \(|z| \leq 1\). The estimates in (17) and (18) are sharp for the functions defined in \( \mathbb{U} \) by
\[
f(z) = \frac{1 + z}{1 - z}, \quad g(z) = \frac{1 + z^2}{1 - z^2}. \quad (20)
\]

We note that the estimate (17) is contained in [9]; the estimate (18) is due to Ma and Minda [18], whereas the results in (19) are obtained by Libera and Złotkiewicz [17] (see also [16]).

2. Main Results

Unless otherwise mentioned, we assume throughout the sequel that \( a \geq c > 0 \).

Now, we solve the Fekete-Szegő problem for the class \( \mathcal{R}(a,c) \).

Theorem 3. If the function \( f \), given by (1), belongs to the class \( \mathcal{R}(a,c) \), then for any \( \lambda \in \mathbb{C} \)
\[
|a_3 - \lambda a_2^2| \leq \frac{1}{2 \left( a_2 \right)^2} \max\left\{ 1, \frac{a \left( c + 1 \right) + 2\lambda c \left( a + 1 \right)}{4a \left( c + 1 \right)} \right\}. \quad (21)
\]

The estimate is sharp.

Proof. From (13), it follows that
\[
\mathcal{L}(a,c) f(z) = \frac{1}{z} \sqrt{1 + \omega(z)} \quad (z \in \mathbb{U}), \quad (22)
\]
where \( \omega \) is analytic and satisfies the conditions \( \omega(0) = 0 \) and \(|\omega(z)| < 1\) in \( \mathbb{U} \). Setting
\[
\phi(z) = \frac{1 + \omega(z)}{1 - \omega(z)} = 1 + p_1 z + p_2 z^2 + \cdots \quad (z \in \mathbb{U}), \quad (23)
\]
we see that \( \phi \in \mathcal{P} \). From the above expression, we get
\[
\omega(z) = \frac{\phi(z) - 1}{\phi(z) + 1} \quad (z \in \mathbb{U}) \quad (24)
\]
so that, by (22), we get
\[
\frac{\mathcal{L}(a,c) f(z)}{z} = \left( \frac{2\phi(z)}{1 + \phi(z)} \right)^{1/2} \quad (z \in \mathbb{U}). \quad (25)
\]

Now, it is easily seen that
\[
\left( \frac{2\phi(z)}{1 + \phi(z)} \right)^{1/2} = 1 + \frac{1}{4} p_1 z + \left( \frac{1}{4} p_2 - \frac{5}{32} p_1^2 \right) z^2
\]
\[+ \left( \frac{1}{4} p_3 - \frac{5}{16} p_1 p_2 + \frac{13}{128} p_1^3 \right) z^3 + \cdots. \quad (26)
\]

Differentiating the series expansion of \( f \) given by (1) with respect to \( z \) and comparing the coefficients of \( z, z^2 \), and \( z^3 \) in (26), we deduce that
\[
a_2 = \frac{c}{4a} p_1 \quad (27)
\]
\[
a_3 = \frac{(c_2)}{(a_2)^2} \left( \frac{1}{4} p_2 - \frac{5}{32} p_1^2 \right) \quad (28)
\]
\[
a_4 = \frac{(c_3)}{(a_2)^3} \left( \frac{1}{4} p_3 - \frac{5}{16} p_1 p_2 + \frac{13}{128} p_1^3 \right) \quad (29)
\]
Thus, by using (27) and (28), we get
\[
|a_3 - \lambda a_2^2| = \frac{1}{2 \left( a_2 \right)^2} \left| p_2 - \frac{5a \left( c + 1 \right) + 2\lambda c \left( a + 1 \right)}{8a \left( c + 1 \right)} p_1^2 \right| \quad (30)
\]
which with the aid of (18) yields the required estimate (21). The estimate (21) is sharp for the function \( f \in \mathcal{A} \) defined in \( \mathbb{U} \) by
\[
f(z) = \varphi(c,a;z) \ast z \sqrt{1+z^2}, \quad (z \in \mathbb{U}), \quad (32)
\]
\[
\varphi(c,a;z) = \left\{ \begin{array}{ll}
\frac{a \left( c + 1 \right) + 2\lambda c \left( a + 1 \right)}{4a \left( c + 1 \right)} & \leq 1 \\
\frac{a \left( c + 1 \right) + 2\lambda c \left( a + 1 \right)}{4a \left( c + 1 \right)} & > 1.
\end{array} \right. \quad (31)
\]

Remark 4. If the function \( f \), given by (1), belongs to the class \( \mathcal{R}(a,c) \), then it follows at once from (27) that \(|a_2| \leq c/2a\) and Theorem 3 gives \(|a_3| \leq (c_2)/2(a_2)^2\). The inequality for \(|a_3|\) is sharp when \( f \) is defined by
\[
f(z) = \varphi(c,a;z) \ast z \sqrt{1+z^2} \quad (z \in \mathbb{U}), \quad (32)
\]
and the estimate for \(|a_3|\) is sharp for the function \( g \) defined by
\[
g(z) = \varphi(c,a;z) \ast z \sqrt{1+z^2} \quad (z \in \mathbb{U}). \quad (33)
\]

For the case \( \lambda \in \mathbb{R} \), Theorem 3 reduces to the following result.
Corollary 5. Let $\lambda \in \mathbb{R}$. If the function $f$, given by (1), belongs to the class $\mathcal{R}(a, c)$, then

\[
\left| a_3 - \lambda a_2^2 \right| \leq \begin{cases} 
- \frac{c}{8a(a_2)} \left[ a(c + 1) + 2\lambda(a + 1)c \right], & \lambda < -\frac{5a(c + 1)}{2(a + 1)c} \\
\frac{(c)}{2(a_2)^2}, & \frac{5a(c + 1)}{2(a + 1)c} \leq \lambda \leq \frac{3a(c + 1)}{2(a + 1)c} \\
\frac{c}{8a(a_2)} \left[ a(c + 1) + 2\lambda c(a + 1) \right], & \lambda > \frac{3a(c + 1)}{2(a + 1)c}.
\end{cases}
\]

The estimate is sharp for the function $f$ defined in $U$ by

\[
f(z) = \varphi(c, a; z) \ast z \sqrt{1 + z},
\]

where

\[
\varphi(c, a; z) = \frac{5a(c + 1)}{2(a + 1)c} \left[ \varphi(c, a; z) \ast z \sqrt{1 + z^2} \right],
\]

\[
\varphi(c, a; z) = \frac{5a(c + 1)}{2(a + 1)c} \left[ \varphi(c, a; z) \ast z \sqrt{1 + z^2} \right],
\]

\[
\varphi(c, a; z) = \frac{5a(c + 1)}{2(a + 1)c} \left[ \varphi(c, a; z) \ast z \sqrt{1 + z^2} \right],
\]

Putting $a = 2$ and $c = 1$ in Corollary 5, we get the following.

Corollary 6. If the function $f$, given by (1), satisfies the subordination relation

\[
f'(z) < \sqrt{1 + z} \quad (z \in U),
\]

then

\[
\left| a_3 - \lambda a_2^2 \right| \leq \begin{cases} 
- \frac{2 + 3\lambda}{48}, & \lambda < -\frac{10}{3} \\
\frac{1}{6}, & -\frac{10}{3} \leq \lambda \leq 2 \\
\frac{2 + 3\lambda}{48}, & \lambda > 2.
\end{cases}
\]

The estimate is sharp for the function $f$ defined in $U$ by

\[
f(z) = \begin{cases} 
\int_0^z \frac{dt}{t - 1} \ast z \sqrt{1 + z}, & \lambda < -\frac{10}{3} \text{ or } \lambda > 2 \\
\int_0^z \frac{dt}{t - 1} \ast z \sqrt{1 + z}, & -\frac{10}{3} \leq \lambda \leq 2
\end{cases}
\]

In the following theorem, we find the sharp upper bound to the second Hankel determinant for the class $\mathcal{R}(a, c)$.

Theorem 7. If $a \geq c \geq 1/2$ and the function $f$, given by (1), belongs to the class $\mathcal{R}(a, c)$, then

\[
\left| a_3 a_4 - a_3^2 \right| \leq \left( \frac{(c)}{2(a_2)^2} \right)^2.
\]

The estimate in (39) is sharp for the function $g$, given by (33).
We next maximize the function \( \mathcal{E}(p, y) \) on the closed rectangle \([0, 2] \times [0, 1] \). Since
\[
\frac{\partial \mathcal{E}}{\partial y} = \frac{c \, (c)_2}{32a \, (a)_2} \left( \frac{a - c}{4(a + 1)_2} \right) (4 - p^2)^{p^2 - 2} \left\{ (a + 2) (c + 1) - (a - c) p \right\} \frac{2(a + 1)}{y} > 0
\]
for \( 0 < p < 2 \) and \( 0 < y < 1 \), the function \( \mathcal{E}(p, y) \) cannot have a maximum value in the interior of the closed rectangle \([0, 2] \times [0, 1] \). Therefore, for fixed \( p \in [0, 2] \),
\[
\max_{0 \leq y \leq 1} \mathcal{E}(p, y) = \mathcal{E}(p, 1) = \mathcal{F}(p) \quad \text{(say)},
\]
where
\[
\mathcal{F}(p) = \frac{c \, (c)_2}{32a \, (a)_2} \left( \frac{a - c}{4(a + 1)_2} \right) (4 - p^2)^{p^2 - 2} \left\{ (a + 2) (c + 1) - (a - c) p \right\} \frac{2(a + 1)}{y}
\]
\[
\times \left\{ (a - 7c - 2ac - 4) \frac{1}{(a + 1)} \right\} \quad (0 \leq p \leq 2).
\]

Setting
\[
\mathcal{F}'(p) = \frac{c \, (c)_2}{256a \, (a)_2} \left( \frac{a - c}{4(a + 1)_2} \right) (4 - p^2)^{p^2 - 2} \left\{ (a - 7c - 2ac - 4) \frac{1}{(a + 1)} \right\} p = 0,
\]
we note that either \( p = 0 \) or
\[
p^2 = \frac{16 (2ac + 7c - a + 4)}{ac - 21a + 24c + 2} > 4.
\]
Since \( a < 2ac + 7c + 4 \), we further observe that \( \mathcal{F}''(0) < 0 \). Thus, the maximum value of \( \mathcal{F} \) is attained at \( p = 0 \) so that the upper bound in (42) corresponds to \( p = 0 \) and \( y = 1 \) from which we get the assertion of the theorem. \( \square \)

Letting \( a = 2 \) and \( c = 1 \) in Theorem 7, we get the following.

**Corollary 8.** If the function \( f \), given by (1), satisfies the condition (36), then
\[
|a_4| \leq \frac{1}{36} \quad \text{(48)}
\]
and the estimate is sharp for the function \( f \) defined by
\[
f(z) = \int_{0}^{z} \frac{dt}{1-t} \ast \sqrt{1+z^2} \quad (z \in \mathbb{U}).
\]

Next, we find the sharp upper bound for the fourth coefficient of functions belonging to the class \( \mathcal{R}(a, c) \).

**Theorem 9.** If the function \( f \), given by (1), belongs to the class \( \mathcal{R}(a, c) \), then
\[
|a_4| \leq \frac{1}{2} \left( \frac{c}{a} \right)^3 \quad \text{(50)}.
\]
The estimate is sharp.

**Proof.** Using (19) in (29) and following the lines of proof of Theorem 7, we deduce that
\[
|a_4| = \left( \frac{c}{a} \right)^3 \times \left\{ \frac{p^3}{128} - \frac{1}{32} \left( \frac{4 - p^2}{p^2} \right) x \right\} \quad (51)
\]
\[
- \frac{1}{16} \left( \frac{4 - p^2}{p^2} \right) y + \frac{1}{8} \left( 1 - |x|^2 \right) z \quad \text{for some} \, (|x| \leq 1) \quad \text{and} \quad (|z| \leq 1).
\]
By an application of the triangle inequality in the above expression followed by replacement of \( |x| \) by \( y \) in the resulting equation, we obtain
\[
|a_4| \leq \left( \frac{c}{a} \right)^3 \times \left\{ \frac{p^3}{128} + \frac{1}{32} \left( \frac{4 - p^2}{p^2} \right) x \right\} \quad (52)
\]
\[
- \frac{1}{16} \left( \frac{4 - p^2}{p^2} \right) y + \frac{1}{8} \left( 1 - |x|^2 \right) z \quad \text{(say)}.
\]
We next maximize the function \( G(p, y) \) on the closed rectangle \([0, 2] \times [0, 1] \). Since
\[
\frac{\partial G}{\partial y} = \frac{c \, (c)_2}{32a \, (a)_2} \left( \frac{4 - p^2}{p^2} \right) \left\{ p - 4 (2 - p) \right\} y < 0 \quad \text{(53)}
\]
for \( 0 < p < 2 \) and \( 0 < y < 1 \), it follows that \( G(p, y) \) cannot have a maximum value in the interior of the closed rectangle \([0, 2] \times [0, 1] \). Thus, for fixed \( p \in [0, 2] \),
\[
\max_{0 \leq y \leq 1} G(p, y) = G(p, 0) = F(p) \quad \text{(say)},
\]
\[
\max_{0 \leq y \leq 1} G(p, y) = G(p, 0) = F(p) \quad \text{(say)},
\]
where
\[ F(p) = \frac{(c)_3}{128(a)_3} (p^3 - 16p^2 + 64). \] (55)

We further note that
\[ F'(p) = \frac{(c)_3}{128(a)_3} (3p - 32)p = 0 \] (56)

for \( p = 0 \) or \( p = 32/3 \). Since \( F''(0) = -(c)_3/4(a)_3 < 0 \), the function \( F \) attains its maximum value at \( p = 0 \). Thus, the upper bound of the function \( G \) corresponds to \( p = y = 0 \).

Putting \( p = y = 0 \) in (52), we get our desired estimate (50).

The estimate in (50) is sharp for the function \( f \) defined by
\[ f(z) = \varphi(c, a; z) \ast z \sqrt{1 + z^3} \quad (z \in U). \] (57)

Letting \( a = 2 \) and \( c = 1 \) in Theorem 9, we obtain the following.

**Corollary 10.** If the function \( f \), given by (I), satisfies the condition (36), then
\[ |a_4| \leq \frac{1}{8} \] (58)

and the estimate is sharp for the function \( f \) defined by
\[ f(z) = \int_0^z \frac{dt}{1 - t} \ast z \sqrt{1 + z^3} \quad (z \in U). \] (59)

Finally, we obtain a sufficient condition for a function in \( A \) to be in the class \( \mathcal{R}(a, c) \).

**Theorem 11.** Let \( \gamma > 0 \). If \( f \in \mathcal{A} \) satisfies
\[ \text{Re} \left\{ \frac{L(a+1, c) f(z)}{L(a, c) f(z)} \right\} < 1 + \frac{1}{2\alpha\gamma} \quad (z \in U), \] (60)

then
\[ \frac{L(a, c) f(z)}{z} < (1 + z)^{1/\gamma} \quad (z \in U) \] (61)

and the result is the best possible.

**Proof.** Setting
\[ \frac{L(a, c) f(z)}{z} = (1 + w(z))^{1/\gamma} \quad (z \in U) \] (62)

and choosing the principal branch in (62), we see that \( w \) is analytic in \( U \) with \( w(0) = 0 \). Taking the logarithmic differentiation in (62) and using the identity (II) in the resulting equation, we deduce that
\[ \frac{L(a+1, c) f(z)}{L(a, c) f(z)} = 1 + \frac{1}{\alpha\gamma} \frac{zw'(z)}{1 + w(z)} \quad (z \in U). \] (63)

We claim that \( |w(z)| < 1 \) for all \( z \in U \). Otherwise, there exists a point \( z_0 \in U \) such that
\[ \max_{|z| = |z_0|} |w(z)| = |w(z_0)| = 1 \quad (w(z_0) \neq 1). \] (64)

Letting \( w(z_0) = e^{i\theta} \) \((\pi < \theta \leq \pi)\) and applying Jack’s lemma [19], we have
\[ z_0w'(z_0) = kw(z_0) \quad (k \geq 1). \] (65)

Using (65) in (63), we get
\[ \text{Re} \left\{ \frac{L(a+1, c) f(z)}{L(a, c) f(z)} \right\} = 1 + \frac{k}{\alpha\gamma} \text{Re} \left\{ \frac{e^{i\theta}}{1 + e^{i\theta}} \right\} \geq 1 + \frac{1}{2\alpha\gamma}, \] (66)

which contradicts the hypothesis (60). Thus, we conclude that \( |w(z)| < 1 \) for all \( z \in U \) and the assertion of the theorem follows from (62).

To see that the result is the best possible, we consider the principal branch of the function \( f_0 \) defined by
\[ f_0(z) = \varphi(z) \ast z (1 + z)^{1/\gamma} \quad (z \in U). \] (67)

Then, it follows from (67) that
\[ \frac{L(a, c) f_0(z)}{z} = (1 + z)^{1/\gamma} \quad (z \in U). \] (68)

On differentiating the above expression logarithmically followed by the use of the identity (II), we obtain
\[ \frac{L(a+1, c) f_0(z)}{L(a, c) f_0(z)} = 1 + \frac{1}{\alpha\gamma} \frac{z}{1 + z} \] (69)
\[ \rightarrow 1 + \frac{1}{2\alpha\gamma} \quad \text{as} \quad z \rightarrow 1^- . \]

The proof of the theorem is thus completed.

**Remark 13.** Further, by specializing the parameters \( a \) and \( c \), one can obtain interesting subclasses of \( \mathcal{A} \) involving the various operators discussed in the introduction and the corresponding results obtained here can be extended to these classes.
