We deduce a simple representation and the invariant factor decompositions of the subgroups of the group \( \mathbb{Z}_m \times \mathbb{Z}_n \), where \( m \) and \( n \) are arbitrary positive integers. We obtain formulas for the total number of subgroups and the number of subgroups of a given order.

1. Introduction

Let \( \mathbb{Z}_m \) be the group of residue classes modulo \( m \) and consider the direct product \( G = \mathbb{Z}_m \times \mathbb{Z}_n \), where \( m \) and \( n \) are arbitrary positive integers. This paper aims to deduce a simple representation and the invariant factor decompositions of the subgroups of the group \( G \). As consequences we derive formulas for the number of certain types of subgroups of \( G \), including the total number \( s(m, n) \) of its subgroups and the number \( s_k(m, n) \) of its subgroups of order \( k \mid mn \).

Subgroups of \( \mathbb{Z} \times \mathbb{Z} \) (sublattices of the two-dimensional integer lattice) and associated counting functions were considered by several authors in pure and applied mathematics. It is known, for example, that the number of subgroups of index \( n \) in \( \mathbb{Z} \times \mathbb{Z} \) is \( \sigma(n) \), the sum of the (positive) divisors of \( n \). See, for example, [1, 2], [3, item A001615]. Although features of the subgroups of \( G \) not only are interesting by their own but also have applications, one of them is described below; it seems that a synthesis on subgroups of \( G \) cannot be found in the literature.

In the case \( m = n \), the subgroups of \( \mathbb{Z}_n \times \mathbb{Z}_n \) play an important role in numerical harmonic analysis, more specifically in the field of applied time-frequency analysis. Time-frequency analysis attempts to investigate function behavior via a phase space representation given by the short-time Fourier transform [4]. The short-time Fourier coefficients of a function \( f \) are given by inner products with translated modulations (or time-frequency shifts) of a prototype function \( g \), assumed to be well localized in phase space, for example, a Gaussian. In applications, the phase space corresponding to discrete, finite functions (or vectors) belonging to \( \mathbb{C}^L \) is exactly \( \mathbb{Z}_N \times \mathbb{Z}_N \). Concerned with the question of reconstruction from samples of short-time Fourier transforms, it has been found that when sampling on lattices, that is, subgroups of \( \mathbb{Z}_N \times \mathbb{Z}_N \), the associated analysis and reconstruction operators are particularly rich in structure, which, in turn, can be exploited for efficient implementation (cf. [5–7] and references therein). It is of particular interest to find subgroups in a certain range of cardinality; therefore, a complete characterization of these groups helps choose the best one for the desired application.

We recall that a finite Abelian group of order \( > 1 \) has rank \( r \) if it is isomorphic to \( \mathbb{Z}_{n_1} \times \cdots \times \mathbb{Z}_{n_r} \), where \( n_1, \ldots, n_r \in \mathbb{N} \setminus \{1\} \) and \( n_j \mid n_{j+1} \) (\( 1 \leq j \leq r - 1 \)), which is the invariant factor decomposition of the given group. Here the number \( r \) is uniquely determined and represents the minimal number of generators of the group. For general accounts on finite Abelian groups see, for example, [8, 9].

It is known that for every finite Abelian group, the problem of counting all subgroups and the subgroups of a given order reduces to \( p \)-groups, which follows from the properties of the subgroup lattice of the group (see [10, 11]). In particular, for \( G = \mathbb{Z}_m \times \mathbb{Z}_n \), this can be formulated as follows. Assume that \( \gcd(m,n) > 1 \). Then \( G \) is an Abelian
group of rank two, since $G = \mathbb{Z}_u \times \mathbb{Z}_v$, where $u = \gcd(m, n)$ and $v = \lcm(m, n)$. Let $u = p_1^{a_1} \cdots p_r^{a_r}$ and $v = p_1^{b_1} \cdots p_r^{b_r}$ be the prime power factorizations of $u$ and $v$, respectively, where $0 \leq a_j \leq b_j$ ($1 \leq j \leq r$). Then

\[
s(m, n) = \prod_{j=1}^r s(p_j^{a_j}, p_j^{b_j}), \tag{1}
\]

\[
s_k(m, n) = \prod_{j=1}^r s_k(p_j^{a_j}, p_j^{b_j}), \tag{2}
\]

where $k = k_1 \cdots k_r$ and $k_j = p_j^{c_j}$ with some exponents $0 \leq c_j \leq a_j + b_j$ ($1 \leq j \leq r$).

Now consider the $p$-group $\mathbb{Z}_{p^u} \times \mathbb{Z}_{p^v}$, where $0 \leq a \leq b$. This is of rank two for $1 \leq a \leq b$. One has the simple explicit formulae:

\[
s(p^a, p^b) = \frac{(b - a + 1) p^{a+2} - (b - a - 1) p^{a+1} - (a + b + 3) p + (a + b + 1)}{(p - 1)^2}, \tag{3}
\]

\[
s_{p^a}(p^a, p^b) = \begin{cases}
p^{a+1} - 1, & c \leq a \leq b, \\
p^{a+1} - 1, & a \leq c \leq b, \\
p^{a+c+1} - 1, & a \leq b \leq c \leq a + b.
\end{cases} \tag{4}
\]

Formula (3) was derived by Calugăreanu [12, Section 4] and recently by Petrillo [13, Proposition 2] using Goursat’s lemma for groups. Tarnăuceanu [14, Proposition 2.9] and [15, Theorem 3.3] deduced (3) and (4) by a method based on properties of certain attached matrices.

Therefore, $s(m, n)$ and $s_k(m, n)$ can be computed using (1), (3) and (2), (4), respectively. We deduce other formulas for $s(m, n)$ and $s_k(m, n)$ (Theorems 3 and 4), which generalize (3) and (4) and put them in more compact forms. These are consequences of a simple representation of the subgroups of $G = \mathbb{Z}_m \times \mathbb{Z}_n$, given in Theorem 1. This representation might be known, but the only source we could find is the paper [5], where only a special case is treated in a different form. More exactly, in [5, Lemma 4.1] a representation for lattices in $\mathbb{Z}_m \times \mathbb{Z}_n$ of redundancy 2, that is, subgroups of $\mathbb{Z}_m \times \mathbb{Z}_n$ having index $n/2$, is given, using matrices in Hermite normal form. Theorem 2 gives the invariant factor decompositions of the subgroups of $G$. We also consider the number of cyclic subgroups of $\mathbb{Z}_m \times \mathbb{Z}_n$ (Theorem 5) and the number of subgroups of a given exponent in $\mathbb{Z}_m \times \mathbb{Z}_n$ (Theorem 8).

Our approach is elementary, using only simple group-theoretic and number-theoretic arguments. The proofs are given in Section 4.

Throughout the paper we use the following notations: $\mathbb{N} = \{1, 2, \ldots\}$, $\mathbb{N}_0 = \{0, 1, 2, \ldots\}$, $\tau(n)$ and $\sigma(n)$ are the number and the sum, respectively, of the positive divisors of $n$, $\psi(n) = n[1/p]$ is the Dedekind function, $\omega(n)$ stands for the number of distinct prime factors of $n$, $\mu$ is the Möbius function, $\phi$ denotes Euler’s totient function, and $\zeta$ is the Riemann zeta function.

2. Subgroups of $\mathbb{Z}_m \times \mathbb{Z}_n$

The subgroups of $\mathbb{Z}_m \times \mathbb{Z}_n$ can be identified and visualized in the plane with sublattices of the lattice $\mathbb{Z}_m \times \mathbb{Z}_n$. Every two-dimensional sublattice is generated by two basis vectors. For example, Figure 1 shows the subgroup of $\mathbb{Z}_{12} \times \mathbb{Z}_{12}$ having the basis vectors $(3, 0)$ and $(1, 2)$.

This suggests the following representation of the subgroups.

Theorem 1. For every $m, n \in \mathbb{N}_0$, let

\[
I_{mn} := \left\{ (a, b, t) \in \mathbb{N}_0^2 \times \mathbb{N}_0 : a \mid m, b \mid n, 0 \leq t \leq \gcd\left(\frac{n}{b}, a\right) - 1 \right\} \tag{5}
\]

and, for $(a, b, t) \in I_{mn}$, define

\[
H_{ab,t} := \left\{ \left(ia + \frac{jt}{\gcd(a, n/b)}, jb\right) : 0 \leq i \leq \frac{m}{a} - 1, 0 \leq j \leq \frac{n}{b} - 1 \right\}. \tag{6}
\]

Then $H_{ab,t}$ is a subgroup of order $mn/ab$ of $\mathbb{Z}_m \times \mathbb{Z}_n$ and the map $(a, b, t) \mapsto H_{ab,t}$ is a bijection between the set $I_{mn}$ and the set of subgroups of $\mathbb{Z}_m \times \mathbb{Z}_n$.

Note that for the subgroup $H_{ab,t}$, the basis vectors mentioned above are $(a, 0)$ and $(s, b)$, where

\[
s = \frac{ta}{\gcd(a, n/b)}. \tag{7}
\]

This notation for $s$ will be used also in the rest of the paper. Note also that in the case $a \neq m, b \neq n$ the area of
the parallelogram spanned by the basis vectors is $ab$, exactly
the index of $H_{a,b}$.
We say that a subgroup $H = H_{a,b}$ is a subproduct of $\mathbb{Z}_m \times \mathbb{Z}_n$ if $H = H_1 \times H_2$, where $H_1$ and $H_2$ are subgroups of $\mathbb{Z}_m$ and $\mathbb{Z}_n$, respectively.

**Theorem 2.** (i) The invariant factor decomposition of the subgroup $H_{a,b}$ is given by

$$H_{a,b} = \mathbb{Z}_{\alpha} \times \mathbb{Z}_{\beta},$$

where

$$\alpha = \left( \frac{m}{a}, \frac{n}{b}, \frac{ns}{ab} \right), \quad \beta = \frac{mn}{ab\alpha}$$

satisfying $\alpha | \beta$.

(ii) The exponent of the subgroup $H_{a,b}$ is $\beta$.

(iii) The subgroup $H_{a,b}$ is cyclic if and only if $\alpha = 1$.

(iv) The subgroup $H_{a,b}$ is a subproduct if and only if $t = 0$ and $H_{a,b,0} = \mathbb{Z}_{m/\alpha} \times \mathbb{Z}_{n/\beta}$. Here $H_{a,b,0}$ is cyclic if and only if $\gcd(m/a, n/b) = 1$.

For example, for the subgroup represented by Figure 1 one has $m = n = 12$, $a = 3, b = 2, s = 1, \alpha = 2$, and $\beta = 12$, and this subgroup is isomorphic to $\mathbb{Z}_2 \times \mathbb{Z}_{12}$. It is not cyclic and is not a subproduct.

According to Theorem 1, the number $s(m, n)$ of subgroups of $\mathbb{Z}_m \times \mathbb{Z}_n$ can be obtained by counting the elements of the set $I_{m,n}$. We deduce the following.

**Theorem 3.** For every $m, n \in \mathbb{N}$, $s(m, n)$ is given by

$$s(m, n) = \sum_{a|m, b|n} \gcd(a, b)$$

$$= \sum_{d|\gcd(m,n)} \phi(d) \tau\left(\frac{m}{d}\right) \tau\left(\frac{n}{d}\right)$$

$$= \sum_{d|\gcd(m,n)} d \tau\left(\frac{mn}{d^2}\right).$$

Formula (10) is a special case of a formula representing the number of all subgroups of a class of groups formed as cyclic extensions of cyclic groups, deduced by Calhoun [16] and having a laborious proof. Note that formula (10) is given, without proof in [3, item A054584].

Note also that the function $(m, n) \mapsto s(m, n)$ is representing a multiplicative arithmetic function of two variables; that is, $s(mm', nn') = s(m, n)s(m', n')$ holds for any $m, n, m', n' \in \mathbb{N}$ such that $\gcd(mm', nn') = 1$. This property, which is in concordance with (1), is a direct consequence of formula (10). See Section 5.

Let $N(a, b, c)$ denote the number of solutions $(x, y, z, t) \in \mathbb{N}^4$ of the system of equations $xy = a, zt = b, xz = c$.

**Theorem 4.** For every $k, m, n \in \mathbb{N}$, $s_k(m, n)$ is given by

$$s_k(m, n) = \sum_{a|m, b|n \gcd(a,b)=k} \gcd(a, b)$$

$$= \sum_{d|\gcd(m,n)} \phi\left(d^k\right) \tau\left(\frac{m}{d^k}\right) \tau\left(\frac{n}{d^k}\right)$$

$$= \sum_{d|\gcd(m,n)} \phi(d) N\left(\frac{m}{d}, \frac{n}{d}, k \sqrt{\frac{d}{d^k}}\right).$$

The identities (3) and (4) can be easily deduced from each of the identities given in Theorems 3 and 4, respectively.

**Theorem 5.** Let $m, n \in \mathbb{N}$.

(i) The number $c(m, n)$ of cyclic subgroups of $\mathbb{Z}_m \times \mathbb{Z}_n$ is given by

$$c(m, n) = \sum_{a|m, b|n} \gcd(a, b)$$

$$= \sum_{d|\gcd(m,n)} \phi(d) \tau\left(\frac{m}{d}\right) \tau\left(\frac{n}{d}\right)$$

$$= \sum_{d|\gcd(m,n)} \phi(d) \tau\left(\frac{mn}{d^2}\right).$$

(ii) The number of subproducts of $\mathbb{Z}_m \times \mathbb{Z}_n$ is $\tau(m) \tau(n)$ and the number of its cyclic subproducts is $\tau(mn)$.

Formula (17), as a special case of an identity valid for arbitrary finite Abelian groups, was derived by the third author [17, 18] using different arguments. The function $(m, n) \mapsto c(m, n)$ is also multiplicative.

### 3. Subgroups of $\mathbb{Z}_n \times \mathbb{Z}_n$

In the case $m = n$, which is of special interest in applications, the results given in the previous section can be easily used. We point out that $n \mapsto s(n) := s(n, n)$ and $n \mapsto c(n) := c(n,n)$ are multiplicative arithmetic functions of a single variable (sequences [3, items A060724, A0606481]). They can be written in the form of Dirichlet convolutions as shown by the next corollaries.

**Corollary 6.** For every $n \in \mathbb{N}$,

$$s(n) = \sum_{d|n} \phi(d) \tau^2(e)$$

$$= \sum_{d|n} d \tau\left(e^2\right).$$
Corollary 7. For every $n \in \mathbb{N}$,
\[ c(n) = \sum_{d|n} \omega(d) \tau \left( \frac{d^2}{n} \right). \quad (21) \]
Further convolutional representations can also be given; for example,
\[ s(n) = \sum_{d|n} \tau(d) \psi\left(\frac{e}{d}\right), \quad c(n) = \sum_{d|n} \psi(d); \quad (23) \]
all these follow from the Dirichlet-series representations
\[ \sum_{n=1}^{\infty} s(n) = \zeta^3(z) \zeta(z-1) = \zeta(2z), \quad (24) \]
\[ \sum_{n=1}^{\infty} c(n) = \zeta^2(z) \zeta(z-1) = \zeta(2z), \quad (25) \]
valid for $z \in \mathbb{C}, \Re(z) > 2$.

Observe that
\[ s(n) = \sum_{d|n} c(d) \quad (n \in \mathbb{N}), \quad (26) \]
which is a simple consequence of (23) or of (24) and (25). It also follows from the next result.

Theorem 8. For every $n, \delta \in \mathbb{N}$ with $\delta \mid n$, the number of subgroups of exponent $\delta$ of $Z_n \times Z_n$ equals the number of cyclic subgroups of $Z_\delta \times Z_\delta$.

4. Proofs

Proof of Theorem 1. Let $H$ be a subgroup of $G = Z_m \times Z_n$. Consider the natural projection $\pi_2 : G \to Z_n$ given by $\pi_2(x, y) = y$. Then $\pi_2(H)$ is a subgroup of $Z_n$ and there is a unique divisor $b$ of $n$ such that $\pi_2(H) = \langle b \rangle = \{jb : 0 \leq j \leq n/b-1\}$. Let $s \geq 0$ be minimal such that $(s, b) \in H$.

Furthermore, consider the natural inclusion $i_1 : Z_m \to G$ given by $i_1(x) = (x, 0)$. Then $i_1^{-1}(H)$ is a subgroup of $Z_m$ and there exists a unique divisor $a$ of $m$ such that $i_1^{-1}(H) = \langle a \rangle$.

We show that $H = \{ (ia+jb, jb) : i, j \in \mathbb{Z} \}$. Indeed, for every $i, j \in \mathbb{Z}, (ia+jb, jb) = i(a, 0) + j(s, b) \in H$. On the other hand, for every $(u, v) \in H$ one has $v \in \pi_2(H)$ and hence there is $j \in \mathbb{Z}$ such that $v = jb$. We obtain $(u-jb, v) = (u, v) - j(s, b) \in H$ and there is $i \in \mathbb{Z}$ with $u-jb = ia$.

Here a necessary condition is that $(sn/b, 0) \in H$ (obtained for $i = 0$ and $j = n/b$), that is, $a \mid sn/b$, equivalent to $a/gcd(a, n/b) \mid s$. Clearly, if this is verified, then for the above representation of $H$ it is enough to take the values $0 \leq i \leq m/a-1$ and $0 \leq j \leq n/b-1$.

Also, dividing by $a$ we have $s = aq + r$ with $0 \leq r < a$ and $(r, b) = (s, b) - q(a, 0) \in H$, showing that $s < a$, by its minimality. Hence $s = ta/gcd(a, n/b)$ with $0 \leq t \leq gcd(a, n/b)-1$. Thus we obtain the given representation.

Conversely, every $(a, b, t) \in I_{m,n}$ generates a subgroup $H_{a,b,t}$ of order $mn/(ab)$ of $Z_m \times Z_n$ and the proof is complete.

Proof of Theorem 2. (i)-(ii) We first determine the exponent of the subgroup $H_{a,b,t}$, $H_{a,b,t}$ is generated by $(a, 0)$ and $(s, b)$; hence, its exponent is the least common multiple of the orders of these two elements. The order of $(a, 0)$ is $m/a$. To compute the order of $(s, b)$ note that $m 
mid rs$ if and only if $m/gcd(m, s) \mid r$. Thus the order of $(s, b)$ is $\text{lcm}(m/gcd(m, s), n/b)$. We deduce that the exponent of $H_{a,b,t}$ is
\[ \text{lcm} \left( \frac{m}{a}, \frac{m}{gcd(m, s)} \right) \times \frac{n}{b}. \quad (27) \]

For every finite Abelian group the rank of a nontrivial subgroup is at most the rank of the group. Therefore, the rank of $H_{a,b,t}$ is 1 or 2. That is, $H_{a,b,t} = Z_\alpha \times Z_\beta$ with certain $\alpha, \beta \in \mathbb{N}$ such that $\alpha \mid \beta$. Here the exponent of $H_{a,b,t}$ equals that of $Z_\alpha \times Z_\beta$, which is lcm($\alpha, \beta$). Using (ii) already proved we deduce that $B = \beta$. Since the order of $H_{a,b,t}$ is $AB = mm/(ab)$ we have $A = mm/(ab) = \alpha$.

(iii) According to (i) $H_{a,b,t} = Z_\alpha \times Z_\beta$, where $\alpha \mid \beta$. Hence $H_{a,b,t}$ is cyclic if and only if $\alpha = 1$.

(iv) The subgroups of $Z_n$ are of form $\{ia : 0 \leq i \leq m/a - 1\}$, where $a \mid m$, and the properties follow from (6) and (iii).

Proof of Theorem 3. By its definition, the number of elements of the set $I_{m,n}$ is
\[ \sum_{a \mid m, b \mid n} \sum_{0 \leq \phi = gcd(a, n/b) - 1} 1 = \sum_{a \mid m, b \mid n} \gcd(a, n/b) = \sum_{a \mid m, b \mid n} \gcd(a), \quad (28) \]
representing $s(m, n)$. This is formula (10).

To obtain formula (11) apply the Gauss formula $n = \sum_{d|n} \phi(d)$ (n ∈ \mathbb{N}) by writing the following:
\[ s(m, n) = \sum_{a \mid m, b \mid n} \sum_{d|gcd(a, b)} \phi(d) = \sum_{a \mid m} \sum_{d|gcd(a, n/b)} \phi(d) = \sum_{\phi \mid n} \phi(d) \tau \left( \frac{m}{d} \right) \right) \right) \tau \left( \frac{n}{d} \right) \tau \left( \frac{m}{d} \right) \tau \left( \frac{n}{d} \right) \right). \quad (29) \]
Now (12) follows from (11) by the Busche-Ramanujan identity (cf. [19, Chapter 1]):
\[
\tau (m) \tau (n) = \sum_{d \mid \gcd(mn)} \tau \left( \frac{mn}{d^2} \right) \quad (m, n \in \mathbb{N}).
\] (30)

Proof of Theorem 4. According to Theorem 1,
\[
s_k (m, n) = \sum_{a \mid n} \gcd \left( a, \frac{n}{b} \right) \cdot \sum_{c \mid a} \phi (c),
\]
giving (13), which can be written, by Gauss’ formula again, as
\[
s_k (m, n) = \sum_{d \mid \gcd(mn)} \phi \left( \frac{mn}{d} \right) = \sum_{d \mid \gcd(mn)} \phi (d),
\]
(31)
where in the inner sum one has \( c = \frac{mn}{d} \) and obtains (14).

Now, to get (15) write (32) as
\[
s_k (m, n) = \sum_{i = k}^{n} \phi (c) \sum_{j = k}^{n} \phi (c) N \left( \frac{m}{c}, \frac{n}{c}, \frac{k}{c} \right),
\]
(33)
and the proof is complete. □

Proof of Theorem 5. (i) According to Theorems 1 and 2/(ii) and using that \( \sum_{d \mid n} \mu (d) = 1 \) or 0 and according to \( n = 1 \) or \( n > 1 \),
\[
c (m, n) = \sum_{a \mid n} \mu (a) \sum_{b \mid n} \mu (b) \sum_{c \mid a, b} \gcd (a, b, c) = \sum_{a \mid n} \mu (a) \sum_{b \mid n} \mu (b) \sum_{c \mid a, b} \gcd (a, b, c)
\]
(34)
where the inner sum is \( \gcd (a, j) \). Hence
\[
c (m, n) = \sum_{a \mid n, \gcd (a, j) = 1} \mu (a) \gcd (a, j).
\] (35)

Now regrouping the terms according to \( e_i = z \) and \( b = t \) we obtain
\[
c (m, n) = \sum_{a \mid m, \gcd (a, j) = 1} \mu (a) \sum_{e_i \mid z} \gcd (a, j) \sum_{b \mid n, \gcd (b, t) = 1} \mu (b)
\]
(36)
which is (16).

The next results follow applying Gauss’ formula and the Busche-Ramanujan formula, similar to the proof of Theorem 3.

(ii) For the subproducts \( H_{a, b, 0} \) the values \( a \mid m \) and \( b \mid n \) can be chosen arbitrary and it follows at once that the number of subproducts is \( \tau (m) \tau (n) \). The number of cyclic subproducts is
\[
\sum_{a \mid m} \sum_{b \mid n} \mu (a) \mu (b) \sum_{c \mid a, b} \gcd (a, b, c)
\]
(37)
by the inverse Busche-Ramanujan identity. □

Proof of Theorem 8. According to Theorem 2/(ii), the number of subgroups of exponent \( \delta \) of \( Z_m \times Z_n \) is
\[
E_{\delta} (n) = \sum_{a \mid n} \sum_{b \mid n} \mu (a) \mu (b) \sum_{c \mid a, b} \gcd (a, b, c) = 1.
\]
(38)

Write \( a = a n \delta, b = b n \delta, \) and \( s = s n \delta \) with \( \gcd (a_i, b_i, s_i) = 1 \). We deduce, similar to the proof of Theorem 5/(i), that
\[
E_{\delta} (n) = \sum_{a \mid n, \gcd (a, \delta) = 1} \mu (a) \gcd (i, j, k),
\] (39)
which is exactly \( c(\delta, \delta) = c(\delta) \) (cf. (35)). □

5. Further Remarks

(1) As mentioned in Section 2 the functions \( s(m, n) \) and \( c(m, n) \) are multiplicative functions of two variables. This follows easily from formulae (10) and (17), respectively. Namely, according to those formulae \( s(m, n) \) and \( c(m, n) \) are two variables Dirichlet convolutions of the functions \( s(m, n) \) and \( c(m, n) \) respectively, with the constant 1 function, all multiplicative. Since convolution preserves the multiplicativity we deduce that \( s(m, n) \) and \( c(m, n) \) are also multiplicative. See [17, Section 2] for details.

(2) Asymptotic formulas with sharp error terms for the sums \( \sum_{m \leq x} s(m, n) \) and \( \sum_{m \leq x} c(m, n) \) were given in the paper [20].

(3) For any finite groups \( A \) and \( B \) a subgroup \( C = A \times B \) is cyclic if and only if \( \tau_1^{-1}(C) \) and \( \tau_2^{-1}(C) \) have coprime orders, where \( \tau_1 \) and \( \tau_2 \) are the natural inclusions ([21, Theorem 4.2]). In the case \( A = Z_{p^a}, B = Z_{q^b} \) and \( C = H_{a, b, t} \) one has \( \tau_1^{-1}(C) = m / a \) and \( \tau_2^{-1}(C) = \gcd(n/b, ns/ab) \) and the characterization of the cyclic subgroups \( H_{a, b, t} \) given in Theorem 2/(iii) can be
obtained also in this way. It turns out that regarding the sublattice, $H_{a,b}$ is cyclic if and only if the numbers of points on the horizontal and vertical axes, respectively, are relatively prime. Note that in the case $m = n$ the above condition reads $\text{lcm}(a, b, s) = ab$. Thus it is necessary that $n \mid ab$. The subgroup on Figure 1 is not cyclic.

(4) Note also the next formula for the number of cyclic subgroups of $\mathbb{Z}_n \times \mathbb{Z}_n$, derived in \cite[Example 2]{2}:

$$c(n) = \sum_{\text{lcm}(d,e)=n} \gcd(d,e) \quad (n \in \mathbb{N}), \quad (40)$$

where the sum is over all ordered pairs $(d, e)$ such that $\text{lcm}(d, e) = n$. For a short direct proof of (40) write $d = \ell a, e = \ell b$ with $\gcd(a, b) = 1$. Then $\gcd(d, e) = \ell$, $\text{lcm}(d, e) = \ell ab$, and obtain

$$\sum_{\text{lcm}(d,e)=n} \gcd(d,e) = \sum_{\ell \mid n} \ell = \sum_{\ell \mid n} \ell \sum_{\gcd(a,b)=1} \sum_{\gcd(d,e) = \ell} 1 = \sum_{\ell \mid n} \ell \omega(k) = c(n), \quad (41)$$

according to (21).

(5) Every subgroup $K$ of $\mathbb{Z} \times \mathbb{Z}$ has the representation $K = \langle (ia + jb, j \in \mathbb{Z}) \rangle$, where $0 \leq s \leq a$ and $0 \leq b$ are unique integers. This follows like in the proof of Theorem 1. Furthermore, in the case $a, b \geq 1, 0 \leq s \leq a - 1$ the index of $K$ is $ab$ and one obtains at once that the number of subgroups $K$ having index $n (n \in \mathbb{N})$ is $\sum_{a,b} \sum_{s \leq b \leq a - 1} 1 = \sum_{a \mid n} a = \sigma(n)$, mentioned in Section 1.

Conflict of Interests
