1. Introduction

Let \( R \) be a prime ring of characteristic different from 2, with extended centroid \( C \), \( U \) its two-sided Utumi quotient ring, \( F \) a nonzero generalized derivation of \( R \), \( f(x_1, \ldots, x_n) \) a noncentral multilinear polynomial over \( C \) in \( n \) noncommuting variables, and \( a, b \in R \) such that \( a[F(r_1, \ldots, r_k), f(r_1, \ldots, r_k)]b = 0 \) for any \( r_1, \ldots, r_k \in R \). Then one of the following holds: (1) \( a = 0 \); (2) \( b = 0 \); (3) there exists \( \lambda \in C \) such that \( F(x) = \lambda x \), for all \( x \in R \); (4) there exist \( q \in U \) and \( \lambda, \mu \in C \) such that \( F(x) = (q + \lambda)x + xq \), for all \( x \in R \), and \( f(x_1, \ldots, x_n) \) is central valued on \( R \); (5) there exist \( q \in U \) and \( \lambda, \mu \in C \) such that \( F(x) = (q + \lambda)x + xq \), for all \( x \in R \), and \( aq = \mu a \), \( qb = \mu b \).

Let \( f(x_1, \ldots, x_n) \) be a multilinear polynomial over \( C \) in \( n \) noncommuting variables and denote by \( f(X) \) the set of all evaluations of \( f(x_1, \ldots, x_n) \) in \( X \subseteq R \). In case \( f(x_1, \ldots, x_n) \) is not central valued on \( R \), it is well known that the additive subgroup generated by \( f(R) \) contains a noncentral Lie ideal of \( R \). Moreover any noncentral Lie ideal of \( R \) contains all the commutators \( [x, y] \) for \( x, y \) in some nonzero ideal of \( R \), unless \( \text{char}(R) = 2 \) and \( \text{dim}_C RC = 4 \).

In light of this and following the line of investigation of the previous cited papers, in [6] P. H. Lee and T. K. Lee consider the Engel-condition \( [d(x), x]_k = 0 \), in case \( x \in f(I) \), where \( I \) is a two-sided ideal of \( R \). They show that either \( f(x_1, \ldots, x_n) \) is central valued in \( R \) or \( \text{char}(R) = 2 \) and \( R \) satisfies \( s_4 \).

These results indicate that the global structure of a prime ring \( R \) is often tightly connected to the behaviour of additive mappings defined on \( R \), which act on suitable subsets of the whole ring. In [7] De Filippis and di Vincenzo study the left annihilator of the set \( \{d(u)u − ud(u), u \in f(R)\} \), where \( d \) is a derivation. In case the annihilator is not zero, the conclusion is that \( f(x_1, \ldots, x_n) \) is central valued on \( R \). These facts in a prime ring are natural tests which evidence that the set \( \{d(u)u − ud(u), u \in f(R)\} \) is rather large in \( R \).

More recently, Liu [8] and Wang [9] have examined the identity \( a[d(u), u]_k = 0 \), where \( d \) is a derivation of \( R \) and \( u \in
\( f(I) \), where \( I \) is a one-sided ideal of \( R \). In particular, for \( I = R \), if \( a \neq 0 \) and \( f(x_1, \ldots, x_n) \) is not central valued on \( R \), then \( \text{char}(R) = 2 \) and \( R \) satisfies \( s_k \).

In \([10]\) de Filippis considers a similar situation, in the case the derivation \( d \) is replaced by a generalized derivation \( F \). An additive map \( F : R \to R \) is said to be a generalized derivation if there is a derivation \( d \) of \( R \) such that, for all \( x, y \in R \), \( F(xy) = F(x)y + xd(y) \). A significant example is a map of the form \( F(x) = ax + xb \), for some \( a, b \in R \); such generalized derivations are called inner. Generalized derivations have been primarily studied on operator algebras. Therefore any investigation from the algebraic point of view might be interesting (see, e.g., \([11]\)).

The main result in \([10]\) is the following.

**Theorem A.** Let \( R \) be a prime ring of characteristic different from 2, with extended centroid \( C \), \( U \) its two-sided Utumi quotient ring, \( F \neq 0 \) a nonzero generalized derivation of \( R \), \( f(x_1, \ldots, x_n) \) a noncentral multilinear polynomial over \( C \) in \( n \) noncommuting variables, and \( a \in R \) such that
\[
\left[ a \left( f \left( f(1, \ldots, r_n) \right), f(1, \ldots, r_n) \right) \right] = 0 \tag{1}
\]
for any \( r_1, \ldots, r_n \in R \). Then either \( a = 0 \) or one of the following holds:

1. There exists \( \lambda \in C \) such that \( f(x) = \lambda x \), for all \( x \in R \);
2. There exist \( q \in U \) and \( \lambda \in C \) such that \( f(x) = (q + \lambda)x + xq \), for all \( x \in R \), and \( f(x_1, \ldots, x_n)^2 \) is central valued on \( R \).

We would like to remark that the same conclusions hold in case we consider the right annihilator, more precisely.

**Theorem B.** Let \( R \) be a prime ring of characteristic different from 2, with extended centroid \( C \), \( U \) its two-sided Utumi quotient ring, \( F \neq 0 \) a nonzero generalized derivation of \( R \), \( f(x_1, \ldots, x_n) \) a noncentral multilinear polynomial over \( C \) in \( n \) noncommuting variables, and \( a \in R \) such that
\[
\left[ f \left( f(1, \ldots, r_n) \right), f(1, \ldots, r_n) \right] a = 0 \tag{2}
\]
for any \( r_1, \ldots, r_n \in R \). Then either \( a = 0 \) or one of the following holds:

1. There exists \( \lambda \in C \) such that \( f(x) = \lambda x \), for all \( x \in R \);
2. There exist \( q \in U \) and \( \lambda \in C \) such that \( f(x) = (q + \lambda)x + xq \), for all \( x \in R \), and \( f(x_1, \ldots, x_n)^2 \) is central valued on \( R \).

Here we will consider a more general situation, involving a two-sided annihilating condition. More specifically, we study simultaneously left and right annihilators of the set \( \{ F(x), x \in f(R) \} \) and prove the following.

**Theorem 1.** Let \( R \) be a prime ring of characteristic different from 2, with extended centroid \( C \), \( U \) its two-sided Utumi quotient ring, \( F \) a nonzero generalized derivation of \( R \), \( f(x_1, \ldots, x_n) \) a noncentral multilinear polynomial over \( C \) in \( n \) noncommuting variables, and \( a, b \in R \) such that
\[
a \left[ F \left( f\left( r_1, \ldots, r_n \right) \right), f(r_1, \ldots, r_n) \right] b = 0 \tag{3}
\]
for any \( r_1, \ldots, r_n \in R \). Then one of the following holds:

1. \( a = 0 \);
2. \( b = 0 \);
3. There exists \( \lambda \in C \) such that \( f(x) = \lambda x \), for all \( x \in R \);
4. There exist \( q \in U \) and \( \lambda \in C \) such that \( f(x) = (q + \lambda)x + xq \), for all \( x \in R \), and \( f(x_1, \ldots, x_n)^2 \) is central valued on \( R \);
5. There exist \( q \in U \) and \( \lambda, \mu \in C \) such that \( f(x) = (q + \lambda)x + xq \), for all \( x \in R \), and \( qa = \mu a, qb = \mu b \).

**Remark 2.** By the primeness of \( R \) and in light of Theorems A and B, we may assume that \( R \) is not a domain. Moreover, since the center of a prime ring cannot contain nonzero zero-divisors, then neither \( a \in Z(R) \) nor \( b \in Z(R) \). Finally in all that follows we always suppose \( \text{char}(R) \neq 2 \).

In the sequel we will make a frequent use of the following.

**Remark 3.** If \( B \) is a basis of \( U \) over \( C \) then any element of \( T = U \cdot_c C[x_1, \ldots, x_n] \), the free product over \( C \) of the \( C \)-algebra \( U \) and the free \( C \)-algebra \( C[x_1, \ldots, x_n] \) is called generalized polynomial and can be written in the form \( g = \sum \alpha_m m \). In this decomposition the coefficients \( \alpha_m \) are in \( C \) and the elements \( m \) are \( B \)-monomials; that is, \( m_i \equiv q_0 \gamma_1 \cdots y_q \delta_0 \) with \( \delta_i \in B \) and \( y_i \equiv \{ x_1, \ldots, x_n \} \). In \([12]\) it is shown that a generalized polynomial \( g = \sum \alpha m \) is the zero element of \( T \) if and only if all \( \alpha_i \) are zero. Let \( a_1, \ldots, a_k \in U \) be linearly independent over \( C \) and \( a_1 g_1(x_1, \ldots, x_n) + \cdots + a_k g_k(x_1, \ldots, x_n) = 0 \in T \), for some \( g_1, \ldots, g_k \in T \). If, for any \( i \), \( g_i(x_1, \ldots, x_n) = \sum_{j=1}^n x_i h_j(x_1, \ldots, x_n) \) and \( h_j(x_1, \ldots, x_n) \in T \), then \( g_i(x_1, \ldots, x_n), g_k(x_1, \ldots, x_n) \) are the zero element of \( T \). The same conclusion holds if \( g_i(x_1, \ldots, x_n) \neq 0 \) for some \( i \) and \( x_i \in C \). We refer the reader to \([1, 12]\) for more details on generalized polynomial identities.

### 2. An Independent Result

We will dedicate this section to the proof of the following proposition on linear identities with commutators in matrix rings. This result will be useful in the sequel.

**Proposition 4.** Let \( C \) be a field and \( R = M_n(C) \) the algebra of \( n \times n \) matrices over \( C \) and \( S = [R, R] \). Let \( a, b, c \in R \), such that \( c \notin Z(R) \) and \( [a(c, x)b] = 0 \) for all \( x \in S \). Then there exists \( \lambda \in Z(R) \) such that \( ac = \lambda \) and \( cb = \lambda b \).

In order to prove Proposition 4, we need several lemmas.

**Lemma 5.** Let \( K \) be an infinite field and \( t \geq 2 \). If \( A_1, \ldots, A_k \) are not scalar matrices in \( M_n(K) \), then there exists some invertible matrix \( B \in M_n(K) \) such that each matrix \( BA_1B^{-1}, \ldots, BA_kB^{-1} \) has all nonzero entries.

**Proof.** See Lemma 1.5 in \([13]\).
Lemma 6. Let $R$ be a prime ring with extended centroid $C$. Suppose $\sum_{i=1}^{m}a_ixb_i + \sum_{j=1}^{m}cxd_j = 0$, for all $x \in R$, where $a_1, b_1, c, d_1 \in R$, for $i = 1, \ldots, n$ and $j = 1, \ldots, m$. If $a_1, \ldots, a_n$ are $C$-independent then each $b_i$ is $C$-dependent on $d_1, \ldots, d_m$. Analogously if $b_1, \ldots, b_n$ are $C$-independent then each $a_i$ is $C$-dependent on $c_1, \ldots, c_m$.

Proof. It is Martindale's result contained in [14].

Lemma 7. Let $R$ be a prime ring with extended centroid $C$. Suppose $a[x, y] + [x, y]b = 0$, for all $x, y \in R$, where $a, b \in R$. Then $a = -b \in C$.

Proof. It is an easy consequence of Lemma 6.

Lemma 8. Let $K$ be an infinite field, $R = M_m(K)$ the algebra of $m \times m$ matrices over $K$, $Z(R)$ the center of $R$, and $S = [R, R]$. Assume that there exist $a, b, c, q$ nonzero elements of $R$ such that $aq + cbx = 0$ for all $x \in S$. If $q \in Z(R)$ then one of the following holds:

(1) $a, b, c$ are central matrices and $aq + bc = 0$;

(2) $b$ is a central matrix and $aq + bc = 0$.

Proof. Since $q \in Z(R)$, by the assumption, we have that $aqx + cxb = 0$ for all $x \in S$. Clearly if $c \in Z(R)$ then $aq + xbc = 0$ for all $x \in S$, and by Lemma 7 we get $aq = -bc \in Z(R)$; that is, $a, b, c \in Z(R)$. On the other hand, if $b \in Z(R)$, then $(aq + bc)x = 0$ for all $x \in S$ and it follows easily that $aq + bc = 0$.

In light of this, we consider $c$ and $b$ both nonscalar matrices. We will prove that in this case we get a contradiction.

Here we denote by $e_{ij}$ the usual matrix unit with 1 in the $(i, j)$-entry and zero elsewhere.

By Lemma 5, we can assume that $c$ and $b$ have all nonzero entries, say $c = \sum_{k,l} c_{kl}e_{kl}$ and $b = \sum_{k,l} b_{kl}e_{kl}$, for $0 \neq c_{ij}, 0 \neq b_{ij} \in K$.

Since $c_{ij} \in S$ for all $i \neq j$, then, for any $i \neq j$, $X = aq e_{ij} + ce_{ij}b = 0$ (4)
in particular the $(i, j)$-entry of $X$ is $c_{ij}b_{ij} = 0$, a contradiction.

For sake of clearness, we may write the previous lemma as follows.

Lemma 9. Let $K$ be an infinite field, $R = M_m(K)$ the algebra of $m \times m$ matrices over $K$, $Z(R)$ the center of $R$, and $S = [R, R]$. Let $a_1, a_2, a_3$, $a_4$ be nonzero elements of $R$ such that $a_1xa_2 + a_3xa_4 = 0$ for all $x \in S$. Assume there exists $i \in \{1, 2, 3, 4\}$ such that $a_i \in Z(R)$. Then $a_1 = \alpha a_3$ and $a_2 = -\alpha a_4$, for a suitable $\alpha \in Z(R)$.

Lemma 10. Let $K$ be an infinite field, $R = M_m(K)$ the algebra of $m \times m$ matrices over $K$, and $Z(R)$ the center of $R$. Assume that there exist $a, b, c, q$ nonzero elements of $R$ such that $aq + cxb = 0$ for all $x \in S = [R, R]$. If $q \in Z(R)$ and $b - \alpha q \in Z(R)$, for a suitable $\alpha \in K$, then $b - \alpha q = a + \alpha c = 0$.

Proof. Assume that $a + \alpha c$ is not a scalar matrix. By Lemma 5, we can assume that $a + \alpha c$ and $q$ have all nonzero entries, say $a + \alpha c = \sum_{i,j} t_{ij}e_{ij}$ and $q = \sum_{i,j} q_{ij}e_{ij}$, for $0 \neq t_{ij}, 0 \neq q_{ij} \in K$.

Since $b = \beta l + aq$, for a suitable $\beta \in K$, by our assumption we have that $axq + cx(\beta + \alpha q) = 0$;

that is, $\beta cx + (a + \alpha c)xq = 0$,

for all $x \in S$. In particular for $x = [e_{ii}, e_{ij}] = e_{ij}$, with $i \neq j$, $0 = X = \beta ce_{ij} + (a + \alpha c)e_{ij}q$.

By calculation one has that the $(j, i)$-entry of $X = 0 = t_{ij}q_{ij}$, a contradiction.

Therefore $a + \alpha c$ must be a central matrix. In light of this, there exist $\beta, \gamma \in K$ such that $b = aq + \beta$ and $a = -\alpha c + \gamma$, so that $0 = (\alpha c + \gamma)xq + cx(aq + \beta) = (\gamma X) + \gamma Y$, for all $x \in S = [R, R]$. Once again by Lemma 7 and since $q \notin Z(R)$, it follows that $\beta = \gamma = 0$; that is, $b = aq$ and $a = -\alpha c$.

Lemma 11. Let $K$ be an infinite field, $R = M_m(K)$ the algebra of $m \times m$ matrices over $K$, and $S = [R, R]$. Suppose there exist $a, b, c, q \in R$ such that $aq + cxb = 0$ for all $x \in S$. Denote

$$a = \sum_{k,l} a_{kl}e_{kl}, \quad b = \sum_{k,l} b_{kl}e_{kl},$$

$$c = \sum_{k,l} c_{kl}e_{kl}, \quad q = \sum_{k,l} q_{kl}e_{kl},$$

for suitable $a_{kl}, b_{kl}, c_{kl}$, and $q_{kl}$ elements of $K$. If there are $i \neq j$ such that $q_{ij} \neq 0, c_{ij} \neq 0$, and $b_{ij} = 0$, then $a_{ij} = 0$ and $b_{ik} = 0$ for all $r \neq i$ and $k \neq r$ (i.e., the only nonzero off-diagonal elements of $b$ fall in the $i$th row).

Proof. Consider the assumption $axq + cxb = 0 \ \forall x \in [R, R]$. (9)

In particular, for $x = e_{ij}$, we have $X = ae_{ij}q + ce_{ij}b = 0$;

so that, for all $r \neq i$, the $(r, i)$-entry of the matrix $X = 0 = a_{ir}q_{ji} + c_{mr}b_{ij} + a_{ri}q_{ij}$. Since $q_{ij} \neq 0$, one has $a_{ij} = 0$ for all $r \neq i$, in particular $a_{ij} = 0$. Thus, in case $m = 2$ we are done (since $b_{ij} = a_{ij} = 0$).

Assume in what follows that $m \geq 3$, and choose $x = e_{ii}$, with $t \neq i, j$. Hence we also have $Y = ae_{ii}q + ce_{ij}b = 0$. (11)

From the previous equalities it follows that

(1) for all $s \neq i$, the $(j, s)$-entry of the matrix $X$ is $a_{js}q_{ji} + c_{js}b_{ij} = 0$;

(2) for all $s \neq i, j$, the $(j, s)$-entry of the matrix $Y$ is $a_{js}q_{is} + c_{js}b_{is} = 0$;
(3) the $(j, i)$-entry of the matrix $Y$ is $a_{ji}q_{ji} + c_{ji}b_{ji} = 0$;
(4) for all $k \neq i, t$, the $(j, k)$-entry of the matrix $Y$ is $a_{ji}q_{jt} + c_{ji}b_{kt} = 0$ (note that this holds also in case $k = j$).

By (1) and (2) and since $a_{ji} = 0$ and $c_{ji} \neq 0$, we have both $b_{ji} = 0$, for all $s \neq i$, and $b_{ki} = 0$ for all $t \neq i, j$ and $s \neq i, j$. So by (3) $b_{ki} = 0$ for all $t \neq i$. Finally by (4), $b_{kt} = 0$ for all $t \neq i, j$ and $k \neq t$.

Lemma 12. Let $K$ be an infinite field, $R = M_m(K)$ the algebra of $m \times m$ matrices over $K$, and $S = [R, R]$. Suppose there exist $a, b, c, q \in R$ such that $axq + cxb = 0$ for all $x \in S$. Denote

$$b = \sum_{kl} b_{kl}e_{kl}, \quad c = \sum_{kl} c_{kl}e_{kl}, \quad q = \sum_{kl} q_{kl}e_{kl} \quad (12)$$

for suitable $b_{kl}, c_{kl}, q_{kl}$ elements of $K$. Assume there are $i \neq j$ such that $b_{ji} = 0$. If $q_{rs} \neq 0$, $c_{rs} \neq 0$ for all $r \neq s$, then one of the following holds:

$(1) \ a = b = 0$;
$(2) \ m = 2, eq = 0, and there exists $0 \neq \lambda \in K$ such that

$$a = \begin{bmatrix} 0 & \lambda c_{12} \\ 0 & \lambda c_{22} \end{bmatrix}, \quad b = \begin{bmatrix} -\lambda q_{11} - \lambda q_{12} \\ 0 \\ 0 \end{bmatrix}. \quad (13)$$

Proof. Firstly we consider the case $m \geq 3$. The first step is to apply twice Lemma 11: this forces $b$ to be a diagonal matrix. In fact $b_{ji} = 0, q_{ij} \neq 0, c_{ij} \neq 0$ imply that $b_{ij} = 0$ for all $r \neq i$ and $k \neq r$; in particular, since $m \geq 3$, there exists $t \neq i$ such that $b_{it} = 0$, for all $l \neq t, i$. Since $q_{kl} \neq 0, c_{kl} \neq 0$, we have $b_{ik} = 0$ for all $r \neq t$ and $k \neq r$, so $b_{yk} = 0$ for all $k \neq i$, as required. Say $b = \sum_{kl} b_{kl}e_{kl}$.

Consider now the inner automorphism of $R$ induced by the invertible matrix $P = I + e_{ij}$, for $r \neq i, j; \varphi(x) = xP^{-1}xP$. Of course $\varphi(axq + cxb) = 0$, for all $x \in S$. Moreover the $(j, i)$-entries of $\varphi(q)$, $\varphi(c)$, and $\varphi(b)$ are, respectively, $q_{ji} \neq 0, c_{ji} \neq 0$, and $b_{ji} = 0$. Therefore, again by Lemma 11, any $(r, k)$-entry of $\varphi(b)$ is zero, for all $r \neq i$. By calculations $0 = (\varphi(q)b)_{ij} = b_{ji} - b_{ri}$; that is, $b_{ji} = b_{ri}$.

On the other hand, if $x$ is the inner automorphisms induced by the invertible matrix $Q = I + e_{ii}$, as above $\chi(a)\chi(x) + \chi(c)\chi(b) = 0$, for all $x \in S$. Since the $(i, j)$-entries of $\chi(q)$, $\chi(c)$, and $\chi(b)$ are, respectively, $q_{ij} \neq 0, c_{ij} \neq 0$, and $b_{ij} = 0$, and again any $(r, i)$-entry of $\chi(b)$ is zero, for all $r \neq i; j$; that is, $0 = (\chi(b))_{ij} = b_{ij} - b_{ri}$ and $b_{ij} = b_{ri} = b_{ij} = \beta$, for all $r \neq i, j$. Thus $b = \beta I$ is a central matrix in $R$. By Lemma 9, either $b = \alpha q$ for some $\alpha \in K$ or $b = 0$. Since the first case cannot occur, we get $b = 0$ and also $a = 0$ which follows from $a[R, R]q = 0$ and $q \neq 0$.

Let now $m = 2$; that is, $R = M_2(K)$. In this case it is well known that for any element $x \in [R, R]$ there exist $\alpha, \beta, \gamma \in K$ such that $x = \begin{bmatrix} \alpha & \beta \\ \gamma & -\alpha \end{bmatrix}$. Without loss of generality we may assume $b_{21} = 0$. In case $b_{21} = 0$, then by the same above argument we show that $b \in Z(R)$ and we are done again. Thus we consider the case $b_{21} \neq 0$. Moreover, by applying Lemma 11 it follows $a_{21} = 0$. Hence we may write

$$a = \begin{bmatrix} a_{11} & a_{12} \\ 0 & a_{22} \end{bmatrix}, \quad b = \begin{bmatrix} b_{11} \\ b_{12} \\ 0 \end{bmatrix}, \quad (14)$$

For $x = e_{12} \in [R, R]$ we have

$$X = ae_{12}q + ce_{12}b = 0 \quad (15)$$

so that the $(2, 2)$-entry of the matrix $X = 0 = c_{21}b_{22};$ that is, $b_{22} = 0$ and the $(1, 1)$-entry of the matrix $X = 0 = a_{11}q_{21};$ that is, $a_{11} = 0$. On the other hand, for $x = e_{21} \in [R, R]$, we have

$$Y = ae_{21}q + ce_{21}b = 0. \quad (16)$$

The $(1, 2)$-entry of the matrix $Y$ is $0 = a_{12}q_{21} + c_{12}b_{21};$ that is, $a_{12} \neq 0$ and $b_{12}/q_{12} = -a_{12}/c_{12}$. Moreover the $(2, 2)$-entry of the matrix $Y$ is $0 = a_{22}q_{21} + c_{22}b_{22}. Therefore, if denoted $\lambda = -b_{12}/q_{12}$, one has $a_{22} = \lambda c_{22}$ and $a_{12} = \lambda c_{12}$.

Analogously, the $(1, 1)$-entry of the matrix $Y = 0 = a_{12}q_{11} + c_{12}b_{11}. Thus b_{11} = -\lambda q_{11} and b_{12} = -\lambda q_{12}.

Finally, by our assumption and for $x = \begin{bmatrix} \alpha & \beta \\ \gamma & -\alpha \end{bmatrix}$, with $\alpha \neq 0$, we also have

$$\begin{bmatrix} 0 & \lambda c_{12} \\ 0 & \lambda c_{22} \end{bmatrix}, \begin{bmatrix} \alpha & \beta \\ \gamma & -\alpha \end{bmatrix}, \begin{bmatrix} q_{11} \\ q_{21} \\ q_{22} \end{bmatrix}$$

and by easy calculations it follows $cq = 0$.

Lemma 13. Let $K$ be an infinite field, $R = M_2(K)$ the algebra of $m \times m$ matrices over $K$, and $S = [R, R]$. Let $a, b, c \in R$ and denote

$$a = \sum_{kl} a_{kl}e_{kl}, \quad b = \sum_{kl} b_{kl}e_{kl}, \quad c = \sum_{kl} c_{kl}e_{kl}, \quad cb = \sum_{kl} p_{kl}e_{kl} \quad (18)$$

for suitable $a_{kl}, b_{kl}, c_{kl}, p_{kl}$ elements of $K$. Suppose $c \notin Z(R)$ and $a, c, x \in S$. Assume there are $i \neq j$ such that $p_{ji} = 0$. If $a_{ij} \neq 0, b_{ij} = 0$, for all $r \neq s$, then $ac = cb = 0$.

Proof. By our hypothesis, we have $axcb - acxb = 0$ for all $x \in S$. By Lemma 12 it follows that either $ac = cb = 0$ or $ab = 0$ and there exists $0 \neq \lambda \in K$ such that

$$ac = \begin{bmatrix} 0 & \lambda a_{12} \\ 0 & \lambda a_{22} \end{bmatrix}, \quad cb = \begin{bmatrix} \lambda b_{11} \\ \lambda b_{12} \end{bmatrix}. \quad (19)$$

Notice that $ab = 0$ implies that the following holds:

$$a_{11}b_{11} + a_{12}b_{21} = 0, \quad (20)$$
$$a_{12}b_{12} + a_{22}b_{22} = 0. \quad (21)$$

Moreover, by computing the product $ac$ we get

$$a_{11}c_{11} + a_{12}c_{21} = 0, \quad (22)$$
$$a_{21}c_{12} + a_{22}c_{22} = \lambda a_{12}. \quad (24)$$
Finally, by computing the product $cb$ we also have
\[ c_1b_1 + c_2b_2 = 0, \]  
\[ c_1b_2 + c_2b_1 = 0. \]  
(25)  
(26)

Notice that, in case $a_{11} = 0$, by (20) it follows the contradiction $a_{12}b_{21} = 0$. Thus $a_{11} \neq 0$ and multiply (25) by $a_{11}$, so that $c_1b_{11}a_{11} + c_2b_{21}a_{11} = 0$. Again by (20) we have $b_21(c_2a_{11} - c_1a_{11}) = 0$ and using (22) it follows $b_{21}(c_2a_{11} + c_1a_{11}) = 0$. Since $b_{21} \neq 0$ and $a_{11} \neq 0$, then $c_{11} = -c_{22} = \mu$.

Assume $\mu \neq 0$, denoted by $I$ the identity matrix in $R$, and let $c' = c - \mu I = \begin{bmatrix} 0 & c_2 \\ c_1 & -2\mu \end{bmatrix}$.

Since $c$ and $c'$ induce the same inner derivation, then by our assumptions we have that $a[c', x]b = 0$ for all $x \in S$. By applying again Lemma 12, it follows that either $ac' = c'b = 0$ or $ab = 0$ and there exists $0 \neq \nu \in K$ such that
\[ ac' = \begin{bmatrix} 0 & \nu a_{12} \\ 0 & \nu a_{22} \end{bmatrix}, \quad c'b = \begin{bmatrix} \nu b_{12} \\ 0 \nu b_{22} \end{bmatrix}. \]  
(27)

In the latter case, by using the same above argument, the matrix $c'$ satisfies the equalities (22) and (25); that is, respectively,
\[ a_{12}c_{21} = 0 \]  
(28)

implying $c_{21} = 0$, and
\[ -2\mu b_{21} = 0 \]  
(29)

which is a contradiction.

Therefore
\[ ac' = c'b = 0, \quad \text{i.e.,} \quad ac = \mu a, \quad cb = \mu b. \]  
(30)

In this case, by using both (22) and (30), the $(1, 1)$-entry of the matrix $ac$ should be
\[ 0 = a_{11}c_{11} + a_{12}c_{21} = \mu a_{11} \neq 0. \]  
(31)

The previous contradiction implies $\mu = 0$; that is, $c_{21} = 0$ and by (26) also $c_2 = 0$. Hence $c = \begin{bmatrix} 0 & c_2 \\ 0 & 0 \end{bmatrix}$.

Now consider the following elements in $S$:
\[ x_0 = \begin{bmatrix} 1 & 1 \\ -1 & -1 \end{bmatrix}, \quad y_0 = \begin{bmatrix} 1 & -1 \\ 1 & 1 \end{bmatrix}. \]  
(32)

Thus
\[ Z = a[c, x_0]b = 0 \quad T = a[c, y_0]b = 0 \]  
(33)

and in particular the $(1, 1)$-entry of $Z$ is
\[ c_1(-a_{11}b_{11} - 2a_{12}b_{21} + a_{21}b_{21}) = 0, \]  
(34)

and the $(1, 1)$-entry of $T$ is
\[ c_1(a_{11}b_{11} - 2a_{12}b_{21} - a_{21}b_{21}) = 0. \]  
(35)

Since $c \neq 0$, then $c_{12} \neq 0$. Therefore the sum of (34) and (35) forces the contradiction $-4a_{11}b_{21} = 0$.

Lemma 14. Let $K$ be an infinite field, $R = M_n(K)$ the algebra of $n \times n$ matrices over $K$, and $S = [R, R]$. Let $a, b, c \in R$ and denote
\[ a = \sum_{KL} a_{KL}e_{KL}, \quad b = \sum_{KL} b_{KL}e_{KL}, \quad cb = \sum_{KL} p_{KL}e_{KL}, \quad ac = \sum_{KL} q_{KL}e_{KL} \]  
(36)

for suitable $a_{KL}, b_{KL}, p_{KL}, q_{KL}$ elements of $K$. Suppose $c \notin Z(R)$ and $a[c, x]b = 0$ for all $x \in S$. Then there exists $\lambda \in Z(R)$ such that $ac = \lambda a$ and $cb = \lambda b$.

Proof. Clearly if one of $a, b, c$, or $cb$ is a scalar matrix we are done by Lemma 9. In order to prove this lemma, we may assume that $a, b, cb, ac$, and $cb$ are noncentral matrices.

By Lemma 5, there exists some invertible matrix $Q \in M_n(K)$ such that $QaQ^{-1} = a'$, $QbQ^{-1} = b'$, $Q(ac)Q^{-1} = (ac)'$, and $Q(cb)Q^{-1} = (cb)'$ have all nonzero entries.

Notice that $\{ac, a\}$ are linearly $Z(R)$-dependent if and only if $\{ac', a'\}$ are linearly $Z(R)$-dependent; analogously $\{cb, b\}$ are linearly $Z(R)$-dependent if and only if $\{cb', b'\}$ are linearly $Z(R)$-dependent. Moreover $ac = cb = 0$ if and only if $(ac)' = (cb)' = 0$. Therefore, in order to prove our result, we may replace $a, b, ac, cb$ respectively by $a', b', (ac)', (cb)'$, so that $a, b, ac, cb$ have all nonzero entries.

For $x = e_{ij} \in S$ we have
\[ X = ace_{ij}b - ae_{ij}cb = 0; \]  
(37)

in particular the $(j, i)$-entry of $X$ is $q_{ij}b_{ji} - a_{ji}p_{ji} = 0$. Denote $0 \neq \eta = q_{ij}/a_{ji}$, so that $p_{ji} = \eta b_{ji}$. Let $I$ be the identity matrix in $R$ and $u = c - \eta I$. Since $u$ and $c$ induce the same inner derivation in $R$, then $a[u, x]b = 0$; that is, $a(c - \eta I)x b - ax(c - \eta I)b = 0$, for all $x \in S$. Moreover $a$ and $b$ have all nonzero entries, and the $(j, i)$-entry of $(c - \eta I)b$ is zero. Thus we may apply Lemmas 12 and 13 and obtain $ac = \eta a$ and $cb = \eta b$, as required.

Proof of Proposition 4. If one assumes that $C$ is infinite, the conclusion follows from Lemma 14.

Now let $K$ be an infinite field which is an extension of the field $C$ and let $R = M_n(K) \cong R\otimes_K C$. Consider the generalized polynomial
\[ P(x_1, x_2) = a[c, x_1, x_2]b \]  
(38)

which is a generalized polynomial identity for $R$. Since $P(x_1, x_2)$ is a multilinear generalized polynomial in the indeterminates $x_1, x_2$, then it is a generalized polynomial identity for $R$ and the conclusion follows again from Lemma 14.

3. The Inner-Case in Prime Rings

In this section we consider $f(R)$, the set of all evaluations of the noncentral multilinear polynomial $f(x_1, \ldots, x_r)$ over $C$, and assume that $F$ is an inner generalized derivation, so that
there exist \( c, q \in U \) such that \( F(x) = cx + xq \), for all \( x \in R \), and \( f(R) \) satisfies
\[
a \left[ cx + xq, x \right] b,
\]
where \( a, b \) are nonzero elements of \( R \).

In order to prove the first result we premit the following.

Fact 1. Let \( R = M_t(C) \) be the algebra of \( t \times t \) matrices over \( C \) of characteristic different from 2. Notice that the set \( f(R) = \{ f(r_1, \ldots, r_n) : r_1, \ldots, r_n \in R \} \) is invariant under the action of all inner automorphisms of \( R \). Hence if denoted by \( r = (r_1, \ldots, r_n) \in R \times R \times \cdots \times R = R^n \), then for any inner automorphism \( \phi \) of \( M_t(C) \), we have that \( r = (\phi(r_1), \ldots, \phi(r_n)) \in R^n \) and \( \phi(f(r)) = f(\phi(r)) \) for all \( r \in R^n \).

Let \( f(x_1, \ldots, x_n) \) be not central then, by [15] (see also [16]), there exist \( u_1, \ldots, u_n \in M_t(C) \) and \( \alpha \in C - \{0\} \), such that \( f(u_1, \ldots, u_n) = \alpha e_{ij} \), with \( k \neq l \). Moreover, since the set \( \{ f(v_1, \ldots, v_n) : v_1, \ldots, v_n \in M_t(C) \} \) is invariant under the action of all \( C \)-automorphisms of \( M_t(C) \), then for any \( i \neq j \) there exist \( r_1, \ldots, r_n \in M_t(C) \) such that \( f(r_1, \ldots, r_n) = \alpha e_{ij} \).

Now we may start with the following.

Proposition 15. Let \( C \) be a field, \( R = M_t(C) \) the algebra of \( t \times t \) matrices over \( C \), and \( f(x_1, \ldots, x_n) \) a noncentral multilinear polynomial over \( C \). Let \( 0 \neq a, 0 \neq b, c, q \in R \) and denote
\[
a = \sum_{kl} a_{kl} e_{kl}, \quad b = \sum_{kl} b_{kl} e_{kl},
c = \sum_{kl} c_{kl} e_{kl}, \quad q = \sum_{kl} q_{kl} e_{kl}
\]
for suitable \( a_{kl}, b_{kl}, c_{kl}, \) and \( q_{kl} \) elements of \( C \). Suppose that
\[
a \left[ cf(r_1, \ldots, r_n) + f(r_1, \ldots, r_n) q, f(r_1, \ldots, r_n) \right] b = 0 \quad (41)
\]
for all \( r_1, \ldots, r_n \in R \). Then one of the following holds:

1. \( c, q \in Z(R) \);
2. there exists \( \lambda \in Z(R) \) such that \( c - q = \lambda, \) and \( f(x_1, \ldots, x_n)^2 \) is central valued on \( R \);
3. there exist \( \lambda, \mu \in Z(R) \) such that \( c - q = \lambda, \) \( ac = \mu a \) and \( cb = \mu b \).

Proof. By our assumption, \( R \) satisfies the following generalized polynomial identity:
\[
a \left[ cf(x_1, \ldots, x_n) + f(x_1, \ldots, x_n) q, f(x_1, \ldots, x_n) \right] b. \quad (42)
\]
As in the previous section \( e_{ij} \) denotes the matrix unit with 1 in \((i, j)\)-entry and zero elsewhere.

Firstly we assume \( C \) is an infinite field.

Since \( f(x_1, \ldots, x_n) \) is not central then, by Fact 1, for any \( i \neq j \), there exist \( r_1, \ldots, r_n \in M_t(C) \) such that \( f(r_1, \ldots, r_n) = e_{ij} \).

Then we obtain
\[
0 = a \left[ ce_{ij} + e_{ji} q, e_{ji} \right] b = ae_{ji} q e_{ji} b - ae_{ji} c e_{ji} b. \quad (43)
\]
In particular,
\[
a_{ij} \left( q_{ij} - c_{ij} \right) b_{ij} = 0. \quad (44)
\]
In light of Remark 2, we assume that \( a \) and \( b \) are not central matrices. Denote \( w = q - c \) and suppose that \( w \) is not scalar. By Lemma 5 there exists an \( C \)-automorphism \( \phi \) of \( M_t(C) \) such that \( \phi(w) = \phi(q) = a' \), and \( b' = \phi(b) \) have all nonzero entries. Clearly \( w', a', \) and \( b' \) must satisfy the condition (44) and this is a contradiction.

This means that \( c - q = \gamma I \), for some \( \gamma \in C \), and the main condition is now
\[
a \left[ cf(r_1, \ldots, r_n) + f(r_1, \ldots, r_n) c, f(r_1, \ldots, r_n) \right] b = 0, \quad (45)
\]
for all \( r_1, \ldots, r_n \in R \); that is, \( a(c, f(r_1, \ldots, r_n)^2)b = 0 \), for all \( r_1, \ldots, r_n \in R \).

Consider the additive subgroup of \( R \), generated by the set \( S = \{ x^2 : x \in f(R) \} \). By [17], either \( S \subseteq Z(R) \) or the noncentral Lie ideal \( [R, R] \) of \( R \) is contained in \( S \). In the first case we conclude that \( f(x_1, \ldots, x_n)^2 \) is central valued in \( R \) and we are done. In either case we have \( a(c, f(r_1, r_2)^2)b = 0 \), for all \( r_1, r_2 \in R \), and by Proposition 4 we get the required conclusions.

Now let \( K \) be an infinite field which is an extension of the field \( C \) and let \( \overline{R} = M_t(K) \equiv R \otimes_K C \). Notice that the multilinear polynomial \( f(x_1, \ldots, x_n) \) is central-valued on \( R \) if and only if it is central-valued on \( \overline{R} \). Consider the generalized polynomial
\[
P(x_1, \ldots, x_n) = a \big( cf(x_1, \ldots, x_n)^2b - f(x_1, \ldots, x_n)^2 q b + af(x_1, \ldots, x_n)(q - c)f(x_1, \ldots, x_n) \big) b \quad (46)
\]
which is a generalized polynomial identity for \( R \). Moreover it is multihomogeneous of multidegree \((2, \ldots, 2)\) in the indeterminates \( x_1, \ldots, x_n \).

Hence the complete linearization of \( P(x_1, \ldots, x_n) \) is a multilinear generalized polynomial \( \Theta(x_1, \ldots, x_n, y_1, \ldots, y_n) \) in \( 2n \) indeterminates; moreover
\[
\Theta(x_1, \ldots, x_n, x_1, \ldots, x_n) = 2^n P(x_1, \ldots, x_n). \quad (47)
\]
Clearly the multilinear polynomial \( \Theta(x_1, \ldots, x_n, y_1, \ldots, y_n) \) is a generalized polynomial identity for \( \overline{R} \) too. Since \( \text{char}(C) \neq 2 \) we obtain \( P(r_1, \ldots, r_n) = 0 \), for all \( r_1, \ldots, r_n \in \overline{R} \), and the conclusion follows from the argument contained in the first part of this proposition.

Lemma 16. If there exist \( 0 \neq a \in R, 0 \neq b \in R, c, q \in U \) such that \( a(cx + xq)b = 0 \), for all \( x \in f(R) \), then \( R \) satisfies a nontrivial generalized polynomial identity, unless when one of the following holds:

1. \( c, q \in C \);
2. \( c - q \in C \) and there exists \( \lambda \in C \) such that \( ac = \lambda a, \) \( q \lambda = \mu \).

Proof. Assume that \( R \) does not satisfy any nontrivial generalized polynomial identity with coefficients in \( U \). Therefore,

\[
\Phi(x_1, \ldots, x_n) = a[cf(x_1, \ldots, x_n) + f(x_1, \ldots, x_n) q, f(x_1, \ldots, x_n)] b
\]

is a trivial generalized polynomial identity for \( R \). By calculation

\[
\Phi(x_1, \ldots, x_n) = a\left(cf(x_1, \ldots, x_n)^2 + f(x_1, \ldots, x_n) \times (q-c) f(x_1, \ldots, x_n) \right)
- f(x_1, \ldots, x_n)^2 \right) b = 0 \tag{49}
\]

for all \( x_1, \ldots, x_n \in R \). If \( c \in C \) and \( q \in C \), the proof is completed; hence we suppose that \( c \) and \( q \) are not simultaneously central. By Remark 3 and by (49), if \( \{b, qb\} \) are linearly \( C \)-independent then \( R \) satisfies the trivial generalized polynomial identity \( af(x_1, \ldots, x_n)^2 qb = 0 \). It means, since \( a \neq 0 \), \( qb = 0 \), a contradiction. Analogously, if we suppose \( \{a, ac\} \) linearly \( C \)-independent, we get \( ac = 0 \), a contradiction. Therefore there exist \( a, \beta \in C \) such that \( qb = \beta b \) and \( ac = aa \); now (49) becomes

\[
a \left( f(x_1, \ldots, x_n)(q-c) f(x_1, \ldots, x_n) + (\alpha - \beta) f(x_1, \ldots, x_n)^2 \right) b = 0 \tag{50}
\]

for all \( x_1, \ldots, x_n \in R \). Since it is a trivial generalized polynomial identity, then \( c - q = \alpha - \beta \). Moreover, \( \beta b = qb = cb + \beta b - ab \); that is, \( cb = ab \).

Proposition 17. Let \( 0 \neq a, 0 \neq b, c, q \in R \) such that

\[
a[cf(r_1, \ldots, r_n) + f(r_1, \ldots, r_n) q, f(r_1, \ldots, r_n)] b = 0 \tag{51}
\]

for all \( r_1, \ldots, r_n \in R \). Then one of the following holds:

1. \( c, q \in Z(R) \);
2. there exists \( \lambda \in C \) such that \( c - q = \lambda \), and \( f(x_1, \ldots, x_n) \) is central valued on \( R \);
3. there exist \( \lambda, \mu \in C \) such that \( c - q = \lambda, ac = \mu a \), and \( cb = \mu b \).

Proof. By Remark 2 we assume that \( R \) is not a domain. Moreover, by Lemma 16, \( R \) satisfies the nontrivial generalized polynomial identity:

\[
P(x_1, \ldots, x_n) = a[cf(x_1, \ldots, x_n) + f(x_1, \ldots, x_n) q, f(x_1, \ldots, x_n)] b. \tag{52}
\]

By a theorem due to Beidar (Theorem 2 in [18]) this generalized polynomial identity is also satisfied by \( U \). In case \( C \) is infinite, we have \( P(r_1, \ldots, r_n) = 0 \) for all \( r_1, \ldots, r_n \in U \otimes_C \overline{C} \), where \( \overline{C} \) is the algebraic closure of \( C \). Since both \( U \) and \( U \otimes_C \overline{C} \) are centrally closed [19, Theorems 2.5 and 3.5], we may replace \( U \) by \( U \otimes_C \overline{C} \) according to \( C \) being finite or infinite. Thus we may assume that \( R \) is centrally closed over \( C \) which is either finite or algebraically closed. By Martin's theorem [14], \( R \) is a primitive ring having a nonzero socle \( H \) with \( C \) as the associated division ring, and \( eHe \) is a simple central algebra finite dimensional over \( C \), for any minimal idempotent element \( e \in RC \).

In light of Jacobson's theorem [20, page 75] \( R \) is isomorphic to a dense ring of linear transformations on some vector space \( V \) over \( C \).

Assume first that \( V \) is finite-dimensional over \( C \). Then the density of \( R \) on \( V \) implies that \( R \cong M_n(C) \), the ring of all \( k \times k \) matrices over \( C \). Since \( R \) is not commutative we assume \( k \geq 2 \). In this case the conclusion follows by Proposition 15.

Assume next that \( V \) is infinite-dimensional over \( C \). As in Lemma 2 in [21], the set \( f(R) \) is dense on \( R \) and so from \( P(r_1, \ldots, r_n) = 0 \), for all \( r_1, \ldots, r_n \in R \), we have that \( R \) satisfies the generalized identity \( P(x) = a[cx + qx, x] b \). We remark that \( H \) satisfies \( P(x) = a(cx^2 - x^2 q + x(q - c)x) b = 0 \) (see, e.g., [5, proof of Theorem 1]); that is, for all \( r \in H \),

\[
a(cr^2 - r^2 q + r(q - c) r)b = 0. \tag{53}
\]

In this equality we substitute \( r \) with \( ex(1 - e) \), for any nontrivial idempotent element \( e = e^2 \in H \), and obtain

\[
ae x(1 - e)(q - c) ex(1 - e) b = 0. \tag{54}
\]

By the primeness of \( R \), it follows that either \( ae = 0 \) or \( (1 - e)b = 0 \) or \( (1 - e)(q - c)e = 0 \). Here our aim is to prove that in any case \( (1 - e)(q - c)e = 0 \). To do this, we firstly assume that \( ae = 0 \). In (53) replace \( r \) by \( ex \), so that \( ac(ex)^2 b = 0 \), which implies \( ace = 0 \).

Moreover we substitute in (53) \( r \) with \( ex + y(1 - e) \) and by easy computation it follows \( ay(1 - e)(q - c) exb = 0 \); that is, \( (1 - e)(q - c)e = 0 \).

On the other hand, if one supposes \( (1 - e)b = 0 \) and replacing in (53) \( r \) by \( x(1 - e) \), one has \( a(x(1 - e))^2 qb = 0 \), which implies \( (1 - e)qb = 0 \). Finally, if substituted in (53) \( r \) with \( x(1 - e) + cy \), as above we have \( ax(1 - e)(q - c)eyb = 0 \). Thus in any case it follows \( (1 - e)(q - c)e = 0 \).

Similarly one can prove also that \( e(q - c)(1 - e) = 0 \).

Hence \( [q - c, e] = 0 \), for any idempotent element \( e \in H \). Since \( H \) is not a domain, then \( H \) is generated by its minimal idempotent elements; therefore \( [q - c, H] = 0 \); that is, \( q - c \in C \). Let \( \lambda \in C \) such that \( q = c + \lambda \). By our assumption it follows that \( H \) satisfies \( a[cx + xc, x] b \) that is \( H \) satisfies \( a[c, x^2]b \). In this last replace \( x \) by \( x + 1 \) and obtain that \( H \) satisfies \( a[c, 2x]b \). Since \( char(H) \neq 2 \), then \( acr(b - a) = 0 \), for all \( r \in H \). By [14, Lemma 1] it follows that there exists \( \mu \in C \) such that \( ac = \mu a \) and \( cb = \mu b \), unless \( ac = cb = 0 \).

Corollary 18. Let \( a, b, c \in R \) such that \( c \notin C \) and \( f(x_1, \ldots, x_n) \) be a noncentral multilinear polynomial over \( C \). If \( a[c, f(r_1, \ldots, r_n)]_2 b = 0 \), for all \( r_1, \ldots, r_n \in R \), then either \( a = 0 \) or \( b = 0 \).
4. The Main Result

In [11] Lee proved that every generalized derivation can be uniquely extended to a generalized derivation of $U$ and thus all generalized derivations of $R$ will be implicitly assumed to be defined on the whole $U$ and obtained the following result.

**Theorem 19** (Theorem 3 in [11]). Every generalized derivation $F$ on a dense right ideal of $R$ can be uniquely extended to $U$ and assumes the form $F(x) = cx + d(x)$, for some $c \in U$ and a derivation $d$ on $U$.

In this section we denote by $f^d(x_1, \ldots, x_n)$ the polynomial obtained from $f(x_1, \ldots, x_n)$ by replacing each coefficient $\alpha_i$ with $d(\alpha_i)$. Thus we write $d(f(r_1, \ldots, r_n)) = f^d(r_1, \ldots, r_n) + \sum_i f(r_1, \ldots, d(r_i), \ldots, r_n)$, for all $r_1, \ldots, r_n$ in $R$.

In light of this, we finally prove our main result.

**Proof of Theorem 1.** Suppose both $a \neq 0$ and $b \neq 0$. Since $R$ satisfies the generalized differential identity

$$a [ F ( f ( x_1, \ldots, x_n ) ) , f ( x_1, \ldots, x_n ) ] b,$$  

the above cited Lee's result says that $R$ satisfies

$$a [ cf ( x_1, \ldots, x_n ) + d ( f ( x_1, \ldots, x_n ) ) , f ( x_1, \ldots, x_n ) ] b.$$  

If $d$ is an inner derivation induced by an element $q \in U$, then $R$ satisfies the generalized polynomial identity:

$$a [ cf ( x_1, \ldots, x_n ) + qf ( x_1, \ldots, x_n ) - f ( x_1, \ldots, x_n ) q , f ( x_1, \ldots, x_n ) ] b,$$  

which is

$$a [ (c + q) f ( x_1, \ldots, x_n ) - f ( x_1, \ldots, x_n ) q , f ( x_1, \ldots, x_n ) ] b.$$  

In this case we are done by Proposition 17.

Hence let $d$ be an outer derivation of $R$. In this case $R$ satisfies the differential identity:

$$a [ cf ( x_1, \ldots, x_n ) + f^d ( x_1, \ldots, x_n ) + \sum_i f ( x_1, \ldots, d(x_i), \ldots, x_n ), f ( x_1, \ldots, x_n ) ] b.$$  

By Kharchenko's theorem (see [16, 22]), $R$ satisfies the generalized polynomial identity:

$$a [ cf ( x_1, \ldots, x_n ) + f^d ( x_1, \ldots, x_n ) + \sum_i f ( x_1, \ldots, y_i, \ldots, x_n ) ] b,$$  

and in particular, for all $i = 1, \ldots, n$, $R$ satisfies the blended identity

$$a [ f ( x_1, \ldots, x_n ) ] b.$$  

Let $q \in R - Z(R)$ and replace any $y_i$ by $[q, x_i]$. Thus $R$ satisfies

$$a [ \sum_i f ( x_1, \ldots, x_i ) ] b.$$  

that is,

$$a [ q, f ( x_1, \ldots, x_n ) ] b.$$  

By Corollary 18, we get the contradiction $q \in Z(R)$.
