ESTIMATES OF DETERMINANTS AND OF THE ELEMENTS OF THE INVERSE MATRIX UNDER CONDITIONS OF OSTROVSKII THEOREM

ANATOLIY I. PEROV

Received 20 December 2000

In 1951 A. M. Ostrovskii published the remarkable theorem being the far generalization of the known J. Hadamard theorem concerning the matrix with the diagonal predomination [3]. The mentioned Ostrovskii result is the following. Let $A = (a_{ij})$ be the square matrix of the order n . Let for a certain value of the parameter α , $0 < \alpha < 1$, the following conditions be satisfied:

$$|a_{ii}| > p_i^{1-\alpha} q_i^\alpha, \quad i = 1, 2, \dots, n, \quad (1)$$

where

$$p_i = \sum_{j \neq i} |a_{ij}|, \quad q_i = \sum_{j \neq i} |a_{ji}|, \quad i = 1, 2, \dots, n. \quad (2)$$

Then the matrix A is regular. If we put formally in (1) $\alpha = 0$ or $\alpha = 1$, we come to Hadamard theorem for matrices with predomination with respect to the row in the first and with respect to the column in the second case (see [2]). Thus, introducing the parameter α Ostrovskii succeeded in the happy connection of different type conditions and—that is maybe, more important—he opened the way of using Hölder inequality in investigations of tests of the matrix regularity.

(Remember that the matrix is called regular if it has an inverse matrix. Denotation of the sum in (2) means that the summation is taken over all indexes $j = 1, 2, \dots$, except $j = i$.)

In the following presentation magnitudes

$$\sigma_i = \frac{p_i^{1-\alpha} q_i^\alpha}{|a_{ii}|}, \quad i = 1, 2, \dots, n \quad (3)$$

are significant. In the accepted notations Ostrovskii conditions (1) could be now written shortly

$$0 \leq \sigma_i < 1, \quad i = 1, 2, \dots, n. \quad (4)$$

Below we frequently use Hölder inequality which is convenient to take the form

$$\left| \sum_{i=1}^n x_i y_i \right| \leq \left(\sum_{i=1}^n |x_i|^{1/\alpha} \right)^\alpha \left(\sum_{i=1}^n |y_i|^{1/\beta} \right)^\beta, \quad (5)$$

where $\alpha, \beta > 0$ and $\alpha + \beta = 1$. The equality sign in this inequality is true if and only if $\arg(x_i y_i) = \text{const}$ and $|y_i|^{1/\beta} = c|x_i|^{1/\alpha}$ for a certain constant $c > 0$ ($i = 1, 2, \dots, n$).

In this paper, we accept the following order of the location of the material: first we present the proof of Ostrovskii theorem using the contraction condition (Theorem 1); then we point estimates (upper and lower) of the absolute value of the determinant of the matrix satisfying Ostrovskii theorem and also clarify when obtained estimates become equality (Theorem 2); and then we prove the central result containing estimates of the absolute value of inverse matrices where for the diagonal elements it has been possible to obtain both upper and lower estimates of the absolute value (Theorem 3).

We write $A = B + C$ where B is a diagonal matrix with elements $a_{11}, a_{22}, \dots, a_{nn}$. From (1) it follows that the diagonal elements of the matrix A are not equal to zero and, consequently, the matrix B is regular. So we can write $A = B(I + S)$, where I is an identical matrix and $S = B^{-1}C$. Theorem 1 clarifies the geometrical sense of Ostrovskii conditions. Before we formulate it, we suppose that all q_i 's are positive and introduce into consideration the norm

$$\|x\| = \left(\sum_{i=1}^n q_i |x_i|^{1/\alpha} \right)^\alpha. \quad (6)$$

THEOREM 1. *Let Ostrovskii conditions (4) be satisfied. Then the matrix S is a contraction*

$$\|S\| \leq \sigma = \max_{1 \leq i \leq n} \sigma_i < 1, \quad (7)$$

where σ_i is defined by (3) and the norm of the matrix S is induced by the norm (6).

Proof. Let $y = Sx$. Then

$$|a_{ii}| |y_i| \leq \sum_{j \neq i} |a_{ij}| |x_j|. \quad (8)$$

We estimate the sum in the right-hand side using Hölder inequality

$$\begin{aligned} \sum_{j \neq i} |a_{ij}| |x_j| &= \sum_{j \neq i} |a_{ij}|^{1-\alpha} \left(|a_{ij}|^\alpha |x_j| \right) \\ &\leq \left(\sum_{j \neq i} |a_{ij}| \right)^{1-\alpha} \left(\sum_{j \neq i} |a_{ij}| |x_j|^{1/\alpha} \right)^\alpha \\ &= p_i^{1-\alpha} \left(\sum_{j \neq i} |a_{ij}| |x_j|^{1/\alpha} \right)^\alpha. \end{aligned} \quad (9)$$

Using (3) we obtain from (9) that

$$q_i^\alpha |y_i| \leq \sigma_i \left(\sum_{j \neq i} |a_{ij}| |x_j|^{1/\alpha} \right)^\alpha \quad (10)$$

from where, according to (7), we find

$$q_i |y_i|^{1/\alpha} \leq \sigma^{1/\alpha} \sum_{j \neq i} |a_{ij}| |x_j|^{1/\alpha}. \quad (11)$$

The estimate (11) is true for every $i = 1, 2, \dots, n$. Adding all these estimates and raising both parts of the obtained inequality to the power α , we get

$$\left(\sum_{i=1}^n q_i |y_i|^{1/\alpha} \right)^\alpha \leq \sigma \left(\sum_{j=1}^n q_j |x_j|^{1/\alpha} \right)^\alpha \quad (12)$$

from where by the definition of the norm of the vector, (6), the estimate $\|Sx\| \leq \sigma \|x\|$ follows. As the relation (12) is true for every vector x , then $\|S\| \leq \sigma$ and the theorem is proved. $\square$

From Theorem 1, it follows that the matrix $I + S$ has an inverse and the estimate $\|(I + S)^{-1}\| \leq 1/(1 - \sigma)$ also follows (cf. [2, page 205]). Therefore, the matrix A is regular and from the obvious relation $A^{-1} = (I + S)^{-1} B^{-1}$, the estimate

$$\|A^{-1}\| \leq (I + S)^{-1} \|B^{-1}\| \leq \frac{1}{(1 - \sigma) \min_{1 \leq i \leq n} |a_{ii}|} \quad (13)$$

is fulfilled.

THEOREM 2. *Let Ostrovskii conditions (4) be satisfied. Then the estimates*

$$\prod_{i=1}^n (1 - \sigma_i) \leq \left| \frac{\det A}{\det B} \right| \leq \prod_{i=1}^n (1 + \sigma_i) \quad (14)$$

are fulfilled. The equality sign in both upper and lower estimates is valid if and only if the conditions

$$\sigma_i = 0, \quad i = 1, 2, \dots, n \quad (15)$$

are satisfied. (We emphasize that the satisfaction to conditions (15) does not mean that the matrix A is diagonal.)

Proof. The proof is based on the known idea of [1, page 47]. Let the matrix $D = (d_{ij})$ be defined as follows:

$$d_{ij} = \frac{a_{ij}}{(1 \pm \sigma_i) |a_{ii}|}, \quad i, j = 1, 2, \dots, n. \quad (16)$$

Then

$$\left| \frac{\det A}{\det B} \right| = \prod_{i=1}^n (1 \pm \sigma_i) |\det D|, \quad (17)$$

and our problem is reduced to the estimate of the absolute value of the determinant of the matrix D from above or from below depending on the change of the sign in (16). Let $\lambda_1, \lambda_2, \dots, \lambda_n$ be the complete system of eigenvalues of the matrix D . For estimating the determinant, we use the following well-known relation:

$$\det D = \lambda_1, \lambda_2, \dots, \lambda_n, \quad (18)$$

stating that the determinant of the matrix is the product of all its eigenvalues.

Let λ be any eigenvalue of the matrix D , and x be the corresponding eigenvector such that $Dx = \lambda x$. According to (16) we obtain

$$\sum_{j=1}^n a_{ij} x_j = \lambda (|a_{ii}| \pm p_i^{1-\alpha} q_i^\alpha) x_i, \quad i = 1, 2, \dots, n, \quad (19)$$

from where it follows that

$$[a_{ii} - \lambda (|a_{ii}| \pm p_i^{1-\alpha} q_i^\alpha)] x_i + \sum_{j \neq i} a_{ij} x_j = 0, \quad i = 1, 2, \dots, n. \quad (20)$$

The matrix $\tilde{A}$ of the system of homogeneous linear equations (20) coincides with the matrix A , except diagonal elements which are changed to

$$\tilde{a}_{ii} = a_{ii} - \lambda (|a_{ii}| \pm p_i^{1-\alpha} q_i^\alpha), \quad i = 1, 2, \dots, n. \quad (21)$$

We show that no eigenvalue of the matrix D with the plus exceeds 1 by its absolute value. Suppose the contrary—let $|\lambda| > 1$. Then according to (21), we obtain

$$\begin{aligned} |\tilde{a}_{ii}| &= |a_{ii} - \lambda (|a_{ii}| \pm p_i^{1-\alpha} q_i^\alpha)| \geq |\lambda| (|a_{ii}| + p_i^{1-\alpha} q_i^\alpha) - |a_{ii}| \\ &= (|\lambda| - 1) |a_{ii}| + |\lambda| p_i^{1-\alpha} q_i^\alpha > |\lambda| p_i^{1-\alpha} q_i^\alpha \geq p_i^{1-\alpha} q_i^\alpha, \quad i = 1, 2, \dots, n, \end{aligned} \quad (22)$$

that is, for the matrix $\tilde{A}$ Ostrovskii conditions are fulfilled. Therefore the system (20) has only zero solution that contradicts nontriviality of the eigenvector. Thus, by the proved $|\lambda_i| \leq 1$ for $i = 1, 2, \dots, n$, from where according to (18) the estimate $|\det D| \leq 1$ follows. The relation (17) in this case shows that the upper estimate in (14) has been established.

We now show that no eigenvalue of the matrix D with the minus be less than 1 by its absolute value. Suppose the contrary—let $|\lambda| < 1$. Then according to (1) and (21) we find that

$$\begin{aligned} |\tilde{a}_{ii}| &= |a_{ii} - \lambda (|a_{ii}| - p_i^{1-\alpha} q_i^\alpha)| \\ &\geq |a_{ii}| - |\lambda| (|a_{ii}| - p_i^{1-\alpha} q_i^\alpha) \\ &= (1 - |\lambda|) |a_{ii}| + |\lambda| p_i^{1-\alpha} q_i^\alpha \\ &> (1 - |\lambda|) p_i^{1-\alpha} q_i^\alpha + |\lambda| p_i^{1-\alpha} q_i^\alpha \\ &= p_i^{1-\alpha} q_i^\alpha, \quad i = 1, 2, \dots, n, \end{aligned} \quad (23)$$

that is, for the matrix $\tilde{A}$ Ostrovskii conditions are fulfilled. Therefore, the system (20) has only zero solution that contradicts nontriviality of the eigenvector. Thus, by the proved $|\lambda_i| \geq 1$ for $i = 1, 2, \dots, n$, from where according to (18) the estimate $|\det D| \geq 1$ follows. The relation (17) in that case shows that the lower estimate in (14) has been established too.

We show now that the equality signs are possible in (14) if and only if conditions (15) are satisfied. Since the sufficiency of the mentioned conditions follows immediately from (14), we prove only their necessity where, without loss of generality, we suppose in addition that all diagonal elements of A are positive.

If in (14) the equality sign is achieved in the upper (lower) estimate, then $|\det D| = 1$, where the matrix D is taken with the plus (minus) sign. As we have just known in the case under consideration all eigenvalues of the matrix D not exceed (not less than) 1 by their absolute value and hence equality (23) is possible if and only if all eigenvalues have their absolute values equal to 1.

Now, we show that really the equality $|\det D| = 1$ is possible in the only case when all eigenvalues of the matrix D equal to 1 such that $\lambda_1 = \lambda_2 = \dots = \lambda_n = 1$. In fact, if we suppose that for any eigenvalue $\lambda \neq 1$ we have $|\lambda| = 1$, then letting u and v be correspondantly real and imaginary part of λ ($u < 1$), and according to (21), we find that

$$\begin{aligned} |\tilde{a}_{ii}| &= |a_{ii} - \lambda(a_{ii} \pm p_i^{1-\alpha} q_i^\alpha)| = a_{ii} |1 - \lambda(1 \pm \sigma_i)| \\ &= a_{ii} \sqrt{\sigma_i^2 + 2(1 \pm \sigma_i)(1 - u)} \\ &> a_{ii} \sigma_i = p_i^{1-\alpha} q_i^\alpha, \quad i = 1, 2, \dots, n, \end{aligned} \quad (24)$$

that is, for the matrix $\tilde{A}$ Ostrovskii conditions are fulfilled. Therefore, the system (20) has only zero solution inspite of the nontriviality of the eigenvector. Thus, all eigenvalues of the matrix D equal to 1.

Since the sum of eigenvalues of the matrix equals to its trace, we obtain from (16),

$$n = \lambda_1 + \lambda_2 + \dots + \lambda_n = \sum_{i=1}^n \frac{1}{1 \pm \sigma_i}, \quad (25)$$

where the upper (lower) sign corresponds to the matrix D with the plus (minus). It is not difficult to see that, due to nonnegativity of σ_i each of the relations (25) (for plus and minus signs) is possible if and only if conditions (15) are satisfied. The theorem is thus proved. $\square$

THEOREM 3. *Let Ostrovskii conditions (15) be satisfied. Then for elements of the inverse matrix $A^{-1} = (a_{ij}^{(-1)})$, the estimates*

$$\frac{1}{|a_{jj}|(1 + \epsilon_j)} \leq |a_{jj}^{(-1)}| \leq \frac{1}{|a_{jj}|(1 - \epsilon_j)}, \quad j = 1, 2, \dots, n, \quad (26)$$

$$|a_{ij}^{(-1)}| \leq \frac{p_i^{1-\alpha} q_j^\alpha}{|a_{ii}| |a_{jj}| (1 - \epsilon_i)^\alpha (1 - \epsilon_j)^{1-\alpha}}, \quad i \neq j; \quad i, j = 1, 2, \dots, n, \quad (27)$$

are fulfilled, where

$$\epsilon_i = \sigma_i \tilde{\sigma}_i, \quad \tilde{\sigma}_i = \max_{j \neq i} \sigma_j \quad (28)$$

(the last record means that the maximum is taken over all $j = 1, 2, \dots, n$ except $j = i$).

Proof. We fix the number j . Components of the j th column of the matrix A^{-1} form a solution of the system

$$\sum_{k=1}^n a_{ik} x_k = 0, \quad i \neq j; \quad i = 1, 2, \dots, n, \quad (29)$$

$$\sum_{k=1}^n a_{jk} x_k = 1. \quad (30)$$

From (29) we obtain, using Hölder inequality (5), that

$$\begin{aligned} |a_{ii}| |x_i| &\leq \sum_{k \neq i} |a_{ik}| |x_k| = \sum_{k \neq i} |a_{ik}|^{1-\alpha} \left(|a_{ik}|^\alpha |x_k| \right) \\ &\leq \left(\sum_{k \neq i} |a_{ik}| \right)^{1-\alpha} \left(\sum_{k \neq i} |a_{ik}| |x_k|^{1/\alpha} \right)^\alpha \end{aligned} \quad (31)$$

from where it follows that

$$|a_{ii}| |x_i| \leq p_i^{1-\alpha} \left(\sum_{k \neq i} |a_{ik}| |x_k|^{1/\alpha} \right)^\alpha. \quad (32)$$

We multiply both sides of (32) by q_i^α , divide by $|a_{ii}|$ and use (3); further, raise the left- and the right-hand sides of the obtained inequality to the power $1/\alpha$. Then we find that

$$q_i |x_i|^{1/\alpha} \leq \sigma_i^{1/\alpha} \sum_{k \neq i} |a_{ik}| |x_k|^{1/\alpha}, \quad i \neq j. \quad (33)$$

Similarly, from (30) we find that

$$q_j \left| x_j - \frac{1}{a_{jj}} \right|^{1/\alpha} \leq \sigma_j^{1/\alpha} \sum_{k \neq j} |a_{jk}| |x_k|^{1/\alpha}. \quad (34)$$

The main inequalities—(33) and (34)—are obtained and we can go further. First of all, add all inequalities (33); according to (28) we obtain

$$\sum_{i \neq j} q_i |x_i|^{1/\alpha} \leq \tilde{\sigma}_j^{1/\alpha} \sum_{i \neq j} \left(\sum_{k \neq i} |a_{ik}| |x_k|^{1/\alpha} \right). \quad (35)$$

We now write in details the left- and the right-hand sides of this inequality, emphasizing on the left those terms which are included into the estimate (34) and on the right the term containing x_j :

$$\begin{aligned} \sum_{i \neq j} |a_{ji}| |x_i|^{1/\alpha} + \sum_{i \neq j} (q_j - |a_{ji}|) |x_i|^{1/\alpha} \\ \leq \tilde{\sigma}_j^{1/\alpha} q_j |x_j|^{1/\alpha} + \tilde{\sigma}_j^{1/\alpha} \sum_{k \neq j} (q_k - |a_{jk}|) |x_k|^{1/\alpha}. \end{aligned} \quad (36)$$

Since according to (4), $\tilde{\sigma}_j < 1$, then from (36) we find that

$$\sum_{i \neq j} (q_i - |a_{ji}|) |x_i|^{1/\alpha} \leq \frac{\tilde{\sigma}_j^{1/\alpha} q_j |x_j|^{1/\alpha} - \sum_{i \neq j} |a_{ji}| |x_i|^{1/\alpha}}{1 - \tilde{\sigma}_j^{1/\alpha}}. \quad (37)$$

The numerator of the fraction in the right-hand side of (37) is clearly nonnegative, therefore

$$\sum_{i \neq j} |a_{ji}| |x_i|^{1/\alpha} \leq \tilde{\sigma}_j^{1/\alpha} q_j |x_j|^{1/\alpha}. \quad (38)$$

Estimating by (38) the right-hand side of (34), we obtain

$$q_j \left| x_j - \frac{1}{a_{jj}} \right|^{1/\alpha} \leq \sigma_j^{1/\alpha} \tilde{\sigma}_j^{1/\alpha} q_j |x_j|^{1/\alpha}. \quad (39)$$

Reducing q_j , dividing by $|x_j|^{1/\alpha}$ and raising both the left- and the right-hand sides to the power α , we come to the important formula

$$\left| 1 - \frac{1}{a_{jj} x_j} \right| \leq \sigma_j \tilde{\sigma}_j = \epsilon_j. \quad (40)$$

(If $q_j = 0$, then the system (29) and (30) has an evident solution $x_i = 0$ for $i \neq j$ and $x_j = 1/a_{jj}$ so the estimate (40) is obviously true because $\sigma_j = 0$; the value of $|x_j|$ is positive because in the opposite case from (39) it would follow that $x_j = 1/a_{jj}$, and we would have the explicit contradiction.) From the estimate (40) both upper and lower estimates in (26) follow immediately.

In order to obtain estimates for off-diagonal elements of the inverse matrix, we add inequality (34) together with all inequalities (33) (changing beforehand in these inequalities i by s) except the i th one (here we fix the number i too). We obtain

$$q_j \left| x_j - \frac{1}{a_{jj}} \right|^{1/\alpha} + \sum_{s \neq i, j} q_s |x_s|^{1/\alpha} \leq \tilde{\sigma}_i^{1/\alpha} \sum_{k=1}^n \left(\sum_{s \neq i, k} |a_{sk}| \right) |x_k|^{1/\alpha}. \quad (41)$$

We write in details the left- and the right-hand sides of (41), emphasizing the i th and the j th variables and the expression used in the estimate (33):

$$\begin{aligned} & q_j \left| x_j - \frac{1}{a_{jj}} \right|^{1/\alpha} + \sum_{s \neq i, j} |a_{is}| |x_s|^{1/\alpha} + \sum_{s \neq i, j} (q_s - |a_{is}|) |x_s|^{1/\alpha} \\ & \leq \tilde{\sigma}_i^{1/\alpha} \left\{ (q_j - |a_{ij}|) |x_j|^{1/\alpha} + q_i |x_i|^{1/\alpha} + \sum_{k \neq i, j} (q_k - |a_{ik}|) |x_k|^{1/\alpha} \right\}. \end{aligned} \quad (42)$$

Using again condition (4), from (42) we obtain

$$\begin{aligned} & \sum_{s \neq i, j} (q_s - |a_{is}|) |x_s|^{1/\alpha} \\ & \leq \frac{\tilde{\sigma}_i^{1/\alpha} \left\{ (q_j - |a_{ij}|) |x_j|^{1/\alpha} + q_i |x_i|^{1/\alpha} \right\} - q_j \left| x_j - \frac{1}{a_{jj}} \right|^{1/\alpha} - \sum_{s \neq i, j} |a_{is}| |x_s|^{1/\alpha}}{1 - \tilde{\sigma}_i^{1/\alpha}}. \end{aligned} \quad (43)$$

Since the numerator of the fraction in the right-hand side of (43) is nonnegative, we come to the estimate

$$\sum_{s \neq i, j} |a_{is}| |x_s|^{1/\alpha} \leq \tilde{\sigma}_i^{1/\alpha} (q_j - |a_{ij}|) |x_j|^{1/\alpha} + \tilde{\sigma}_i^{1/\alpha} q_i |x_i|^{1/\alpha} - q_j \left| x_j - \frac{1}{a_{jj}} \right|^{1/\alpha}. \quad (44)$$

This formula cannot still be used for the estimate of x_i because in its left side the member $|a_{ij}| |x_j|^{1/\alpha}$ is absent (see formula (33)). We enforce inequality (44) by changing $\tilde{\sigma}_i^{1/\alpha}$ in the first term on the right side by 1. Then we can write

$$\sum_{s \neq i} |a_{is}| |x_s|^{1/\alpha} \leq \tilde{\sigma}_i^{1/\alpha} q_i |x_i|^{1/\alpha} + q_j \left(|x_j|^{1/\alpha} - \left| x_j - \frac{1}{a_{jj}} \right|^{1/\alpha} \right). \quad (45)$$

From (33) and (45) we obtain

$$q_i |x_i|^{1/\alpha} \leq \sigma_i^{1/\alpha} \left\{ \tilde{\sigma}_i^{1/\alpha} q_i |x_i|^{1/\alpha} + q_j \left(|x_j|^{1/\alpha} - \left| x_j - \frac{1}{a_{jj}} \right|^{1/\alpha} \right) \right\} \quad (46)$$

from where the following important relation follows

$$(1 - \epsilon_i^{1/\alpha})^\alpha q_i^\alpha |x_i| \leq \sigma_i q_j^\alpha |x_j| \left(1 - \left| 1 - \frac{1}{a_{jj} x_j} \right|^{1/\alpha} \right)^\alpha. \quad (47)$$

Since the derivative of the function $(1 - u^{1/\alpha})^\alpha / (1 - u)$ being considered on the half-interval $[0, 1)$ is positive, this function is strongly increasing. Therefore, putting $1/(a_{jj} x_j) = 1 - t$ (note that according to (40) $|t| \leq \epsilon_j$), we can write

$$|x_j| \left(1 - \left| 1 - \frac{1}{a_{jj} x_j} \right|^{1/\alpha} \right)^\alpha = \frac{(1 - |t|^{1/\alpha})^\alpha}{|a_{jj}| |1 - t|} \leq \frac{(1 - \epsilon_j^{1/\alpha})^\alpha}{|a_{jj}| (1 - \epsilon_j)}. \quad (48)$$

Now from (47) the intermediate estimate follows

$$|x_i| \leq \frac{\sigma_i q_j^\alpha (1 - \epsilon_j^{1/\alpha})^\alpha}{q_i^\alpha |a_{jj}| (1 - \epsilon_i^{1/\alpha})^\alpha (1 - \epsilon_j)}, \quad (49)$$

which we put, remembering the definition of σ_i (see (3)), into the next form

$$|x_i| \leq \frac{p_i^{1-\alpha} q_j^\alpha (1 - \epsilon_j^{1/\alpha})^\alpha}{|a_{ii}| |a_{jj}| (1 - \epsilon_i^{1/\alpha})^\alpha (1 - \epsilon_j)}. \quad (50)$$

The transition from (47) to (50) was made under the supposition that $q_i > 0$. In the case $q_i = 0$ —there is no arguments to exclude it—instead of the inequality (33) we use the inequality generating (33):

$$|a_{ii}| |x_i| \leq p_i^{1-\alpha} \left(\sum_{k \neq i} |a_{ik}| |x_k|^{1/\alpha} \right)^\alpha. \quad (51)$$

Instead of the estimate (47), we obtain now

$$|a_{ii}| |x_i| \leq p_i^{1-\alpha} q_j^\alpha |x_j| \left(1 - \left| 1 - \frac{1}{a_{jj} x_j} \right|^{1/\alpha} \right)^\alpha, \quad (52)$$

from where we come, as above, to the estimate (50) (note that in the case under consideration $\epsilon_i = 0$).

As we can easily see, the transpose matrix A' satisfies Ostrovskii conditions too where the index α should be changed by the conjugate index $\beta = 1 - \alpha$. In this case quantities σ'_i for the matrix A' coincide with quantities σ_i for the matrix A . Because $(A')^{-1} = (A^{-1})'$, we obtain from the estimate (50), used for the transpose matrix, that

$$|x_i| \leq \frac{p_i^{1-\alpha} q_j^\alpha (1 - \epsilon_i^{1/\beta})^\beta}{|a_{ii}| |a_{jj}| (1 - \epsilon_j^{1/\beta})^\beta (1 - \epsilon_i)}. \quad (53)$$

We can see that the quantity we are interested in admits two different estimates (50) and (53). Therefore, the estimate contains the minimum of two encountered expressions is also true. We would not write this estimate in view of its awkwardness but take up closely the problem being stated to obtain the announced estimate (27).

If $\epsilon_i = \epsilon_j$, then each of estimates (50) and (53) turns into (27). If $\epsilon_i \neq \epsilon_j$, then we reason as follows. Since the derivative of the function $\phi_\gamma(u) = (1 - u)/(1 - u^{1/\gamma})$ where $0 < \gamma < 1$ being considered on the half-interval $[0, 1)$ is negative, this function is strongly decreasing. Therefore if, for example, $\epsilon_i < \epsilon_j$, then putting $\gamma = \beta$ we obtain $\phi_\beta(\epsilon_i) > \phi_\beta(\epsilon_j)$ from where it follows that

$$\frac{(1 - \epsilon_i^{1/\beta})}{(1 - \epsilon_j^{1/\beta})^\beta (1 - \epsilon_i)} = \frac{1}{(1 - \epsilon_i)^\alpha (1 - \epsilon_j)^\beta} \left[\frac{\phi_\beta(\epsilon_j)}{\phi_\beta(\epsilon_i)} \right] < \frac{1}{(1 - \epsilon_i)^\alpha (1 - \epsilon_j)^\beta}, \quad (54)$$

and so the estimate (27) follows immediately from (53), with the strong inequality sign. Similarly if $\epsilon_i > \epsilon_j$, then putting $\gamma = \alpha$ we obtain $\phi_\alpha(\epsilon_i) < \phi_\alpha(\epsilon_j)$ from where repeating the reasons conducted we come from the estimate (50) to the estimate (27) with the strong inequality sign also. The theorem is thus proved. $\square$
