A class of second-order nonlinear impulsive integro-differential equations of mixed type whose principal part is given by time-varying generating operators in fractional power spaces is considered. We introduce the reasonable PC- α -mild solution of second-order nonlinear impulsive integro-differential equations of mixed type and prove its existence. The existence of optimal controls for a Lagrange problem of systems governed by second-order nonlinear impulsive integro-equations of mixed type is also presented. An example is given for demonstration.

1. Introduction

Some interesting models of mathematical biology or population, mechanics of materials, nuclear physics, and so forth, can be written in terms of second-order nonlinear partial integro-differential equations. This is the case of the model proposed to describe viscoelastic problems with memory. The system is given by

$$\begin{aligned} \ddot{x}(t) + A(t)\dot{x}(t) &= f(t, x(t), \dot{x}(t), (Gx)(t), (Hx)(t)), \quad t \in (0, T] \setminus \Theta, \\ x(0) &= x_0, \quad \Delta x(t_i) = J_i^0(x(t_i), \dot{x}(t_i)), \quad t_i \in \Theta, \\ \dot{x}(0) &= x_1, \quad \Delta \dot{x}(t_i) = J_i^1(x(t_i), \dot{x}(t_i)), \quad t_i \in \Theta, \end{aligned} \quad (1.1)$$

where $\{A(t) \mid 0 \leq t \leq T\}$ generates an evolution system $\{U(t, s) \mid 0 \leq s \leq t \leq T\}$ in the parabolic case in Banach spaces X (see [1–3]). G, H are nonlinear integral operators given by

$$(Gx)(t) = \int_0^t k(t, \tau)g(\tau, x(\tau), \dot{x}(\tau))d\tau, \quad (Hx)(t) = \int_0^T m(t, \tau)h(\tau, x(\tau), \dot{x}(\tau))d\tau. \quad (1.2)$$

$\Theta = \{t_i \in (0, T) \mid 0 = t_0 < t_1 < \cdots < t_n < t_{n+1} = T\}$, J_i^0, J_i^1 ($i = 1, 2, \dots, n$) are nonlinear maps, and $\Delta x(t_i) = x(t_i + 0) - x(t_i)$, $\Delta \dot{x}(t_i) = \dot{x}(t_i + 0) - \dot{x}(t_i)$. This represents the jump in the state x , $\dot{x}$ at time t_i , respectively, with J_i^0, J_i^1 determining the size of the jump at time t_i .

In fact, since the end of last century, impulsive evolution equations on infinite-dimensional spaces have been investigated by many authors including us. Particularly, Ahmed and we considered optimal control problems of systems governed by first-order impulsive evolution equations and first-order impulsive integro-differential equations [4–7]. Recently, we discussed the second-order impulsive evolution equations and the second-order impulsive integro-differential equations and their optimal controls in general Banach spaces [8–11]. In addition, to our knowledge, the second-order impulsive functional differential equations and the second-order impulsive integro-differential equations whose principal operator is bounded have been deeply studied by many authors [12–16]. However, the second-order impulsive integro-differential equations of mixed type whose principle operator is unbounded in infinite dimensional fractional power spaces and corresponding optimal control problems have not been extensively considered in the literature.

Reducing the second-order evolution equations to the first-order evolution equations, we introduce a family of unbounded linear matrix operators $\mathfrak{A}(t)$, $0 \leq t \leq T$ and prove that $\{\mathfrak{A}(t) \mid 0 \leq t \leq T\}$ generates an evolution system $\{\bar{U}(t, s) \mid 0 \leq s \leq t \leq T\}$ which can be represented by $U(t, s)$, $0 \leq s \leq t \leq T$. Based on the evolution system $\{\bar{U}(\cdot, \cdot)\}$, we introduce a reasonable PC- α -mild solution of (1.1). Using the interpolation space technique, we can overcome the difficulty brought by fractional power spaces. Next, by a virtue of the generalized Gronwall lemma with singularity, impulse, and integrals of mixed type given by us, one can overcome the difficulty brought by operator H to get a priori estimate of PC- α -mild solution. By compactness condition of space $PC^1([0, T], X_\alpha)$ and Leray-Schauder fixed point theory, we can obtain the existence of PC- α -mild solution for (1.1). Particularly, introducing new norm, we use the contraction mapping principle to give the uniqueness of α -mild solution for the second-order nonlinear integro-differential equation (1.1) without impulses (see Remark 3.4). A Lagrange problem of a system governed by (1.1) whose cost functional includes both x and $\dot{x}$ is investigated. By the structure of $\{\bar{U}(\cdot, \cdot)\}$ and compactness of $\{U(\cdot, \cdot)\}$, the existence of optimal controls is verified.

The rest of the paper is organized as follows. In Section 2, we give some associated notations and important lemmas. In Section 3, the existence of PC- α -mild solution for (1.1) is presented. In Section 4, we consider a Lagrange problem of system governed by (1.1) and prove the existence of optimal controls. At last, an example demonstrates the applicability of our results.

2. Preliminaries

Let X, Y denote a pair of Banach spaces. If X is continuously embedded in Y , we write $X \hookrightarrow Y$; if X is compactly embedded in Y , we write $X \hookrightarrow\hookrightarrow Y$. Set $\bar{\Delta} = \{(t, s) \mid 0 \leq s \leq t \leq T\}$, $\mathcal{L}(X)$ is the class of (not necessarily bounded) linear operators in X . $\mathcal{L}_b(X)$ stands for the family of bounded linear operators in X . For $A \in \mathcal{L}(X)$, let $\rho(A)$ denote the resolvent set and $R(\lambda, A)$ the resolvent corresponding to $\lambda \in \rho(A)$.

Assumption A. (P₁) Let $\{A(t) \mid t \in [0, T]\}$ be a family of closed linear operators in X , the domain $D(A(t)) = D$ of $A(t)$, and $t \in [0, T]$ dense in X and independent of t .

(P₂) For $t \in [0, T]$, the resolvent $R(\lambda, A(t))$ of $A(t)$ exists for all λ with $\operatorname{Re} \lambda \leq 0$ and there exists a constant $M > 0$ such that

$$\|R(\lambda, A(t))\|_{\mathcal{L}(X)} \leq \frac{M}{|\lambda| + 1}, \quad \text{for } t \in [0, T]. \quad (2.1)$$

(P₃) There exist constants $L > 0$ and $0 < \alpha \leq 1$ such that

$$\left\| (A(t) - A(s))A^{-1}(\tau) \right\|_{\mathcal{L}(X)} \leq L|t - s|^\alpha \quad \text{for } s, t, \tau \in [0, T]. \quad (2.2)$$

Let $X_1 = \{D, \|\cdot\|_1\}$ where $\|x\|_1 = \|Ax\|$. X_1 is a Banach space and $X_1 \hookrightarrow X$. More generally, in a usual way we introduce the fractional power operator $A^\alpha(t)$ ($\alpha \in (0, 1)$), which satisfies $D(A) = D(A(t))$ and $D(A^\alpha) = D(A^\alpha(t))$ for $t \in [0, T]$. Let $\|x\|_\alpha = \|A^\alpha x\|$ for $x \in D(A^\alpha(t))$ and denote the Banach space $\{D(A^\alpha), \|\cdot\|_\alpha\}$ as X_α . Then it is clear that $X_\beta \hookrightarrow X_\alpha$ for $0 \leq \alpha \leq \beta \leq 1$. Define $\operatorname{PC}([0, T], X_\alpha) \equiv \{x : [0, T] \rightarrow X_\alpha \mid x \text{ as continuous at } t \in [0, T] \setminus \Theta; x \text{ is continuous from left and has right-hand limits at } t \in \Theta\}$, $\operatorname{PC}^1([0, T], X_\alpha) \equiv \{x \in \operatorname{PC}([0, T], X_\alpha) \mid \dot{x} \in \operatorname{PC}([0, T], X)\}$. It can be seen that $\operatorname{PC}([0, T], X_\alpha)$ and $\operatorname{PC}^1([0, T], X_\alpha)$ are Banach spaces, respectively, with the norms

$$\|x\|_{\operatorname{PC}} = \max \left\{ \sup_{t \in [0, T]} \|x(t+0)\|_\alpha, \sup_{t \in [0, T]} \|x(t-0)\|_\alpha \right\}, \quad \|x\|_{\operatorname{PC}^1} = \|x\|_{\operatorname{PC}} + \|\dot{x}\|_{\operatorname{PC}}. \quad (2.3)$$

For the initial value problem

$$\begin{aligned} \dot{x}(t) + A(t)x(t) &= 0, \quad t \in (0, T], \\ x(0) &= x_0, \end{aligned} \quad (2.4)$$

it is well known that (2.4) has a unique classical solution x . Moreover, $x \in C^1([0, T], X)$ provided $x_0 \in D(A)$. Further, there exists a unique evolution operator $U(t, s) \in L_b(X)$, $(t, s) \in \overline{\Delta}$, such that every solution of (2.4) can be represented in the form

$$x(t) = U(t, 0)x_0. \quad (2.5)$$

Consider the following second-order initial value problem:

$$\begin{aligned} \ddot{x}(t) + A(s)\dot{x}(t) &= 0, \quad t \in (0, T], \\ x(0) &= x_0, \quad \dot{x}(0) = x_1. \end{aligned} \quad (2.6)$$

Set $v(t) = \begin{pmatrix} x(t) \\ \dot{x}(t) \end{pmatrix}$ and $v_0 = \begin{pmatrix} x_0 \\ x_1 \end{pmatrix}$; (2.6) can be rewritten as

$$\begin{aligned} \dot{v}(t) + \mathfrak{A}(t)v(t) &= 0, \quad t \in (0, T], \\ v(0) &= v_0, \end{aligned} \quad (2.7)$$

where $\mathfrak{A}(t) = \begin{pmatrix} 0 & -I \\ 0 & A(t) \end{pmatrix}$. By [9, Theorem 2.A], we have the following theorem.

Theorem 2.1. *Under the Assumption A, (2.7) has a unique evolution system $\{\bar{U}(t, s) \mid (t, s) \in \bar{\Delta}\}$ given by*

$$\bar{U}(t, s) = \begin{pmatrix} I & \int_s^t U(\tau, s) d\tau \\ 0 & U(t, s) \end{pmatrix}. \quad (2.8)$$

In order to derive a priori estimates on the PC- α -mild solution of integro-differential equation of mixed type, we need the following generalized Gronwall inequality with impulses.

Theorem 2.2. *Let $x \in PC([0, T], X_\alpha)$ and satisfy the following inequality:*

$$\|x(t)\|_\alpha \leq a + b \int_0^t |t - \tau|^{-\gamma} \|x(\tau)\|_\alpha d\tau + c \int_0^t |t - \tau|^{-\gamma} \|x_\tau\|_B d\tau + \delta \int_0^T \|x(\tau)\|_\alpha^\lambda d\tau + \sum_{0 < t_k < t} \theta_k \|x(t_k)\|_\alpha \quad (2.9)$$

for all $t \in [0, T]$, where $1 > \lambda$, $\gamma > 0$, and $a, b, c, \delta, \theta_k \geq 0$ are constants, and $\|x_t\|_B = \sup_{0 \leq s \leq t} \|x(s)\|_\alpha$. Then there exists constant $M > 0$ such that

$$\|x(t)\|_\alpha \leq M, \quad \forall t \in [0, T]. \quad (2.10)$$

Proof. By the inequality (2.9) and [7, Lemma 2.1], there exist $a_0 > 0, b_0 > 0$ such that

$$\|x_t\|_B \leq a_0 \left(a + \delta \int_0^T \|x(\tau)\|_\alpha^\lambda d\tau \right) + b_0 \int_0^t \|x_\tau\|_B d\tau + \sum_{0 < t_k < t} a_0 \theta_k \|x(t_k)\|_B. \quad (2.11)$$

By [17, Lemma 1.7.1], we have

$$\begin{aligned} \|x_t\|_B &\leq a_0 \left(a + \delta \int_0^T \|x(\tau)\|_\alpha^\lambda d\tau \right) \prod_{0 < t_k < t} (1 + a_0 \theta_k) e^{b_0 t} \\ &\leq a_0 \left(a + \delta \int_0^T \|x(\tau)\|_\alpha^\lambda d\tau \right) \prod_{0 < t_k < T} (1 + a_0 \theta_k) e^{b_0 T}. \end{aligned} \quad (2.12)$$

Using the argument method [10, Lemma 3.1], there exists constant $M > 0$ such that

$$\|x(t)\|_\alpha \leq M, \quad \forall t \in [0, T]. \quad (2.13)$$

This completes the proof. $\square$

Next, we extend the Ascoli-Arzela Theorem from $C([0, T], X)$ to $PC^1([0, T], X_\alpha)$.

Theorem 2.3. Suppose $\mathcal{W} \subset PC^1([0, T], X_\alpha)$ is a subset. If the following conditions are satisfied:

- (1) $\mathcal{W}$ is uniformly bounded subset of $PC^1([0, T], X_\alpha)$,
- (2) $\mathcal{W}$ is equicontinuous in (t_i, t_{i+1}) , $i = 0, 1, 2, \dots, n$, where $t_0 = 0$, $t_{n+1} = T$,
- (3) its t -sections $\mathcal{W}(t) \equiv \{x(t) \mid x \in \mathcal{W}, t \in [0, T] \setminus \Theta\}$, $\dot{\mathcal{W}}(t) \equiv \{\dot{x}(t) \mid x \in \mathcal{W}, t \in [0, T] \setminus \Theta\}$, $\mathcal{W}(t_i + 0) \equiv \{x(t_i + 0) \mid x \in W\}$, $\mathcal{W}(t_i - 0) \equiv \{x(t_i - 0) \mid x \in \mathcal{W}\}$, $\dot{\mathcal{W}}(t_i + 0) \equiv \{\dot{x}(t_i + 0) \mid x \in W\}$, and $\dot{\mathcal{W}}(t_i - 0) \equiv \{\dot{x}(t_i - 0) \mid x \in \mathcal{W}\}$ are relatively compact subsets of X_α ,

then $\mathcal{W}$ is a relatively compact subset of $PC^1([0, T], X_\alpha)$.

Proof. Let $W = x(\cdot) \in PC^1([0, T], X_\alpha)$ satisfy assumptions of Theorem 2.3 and $\{x_m(\cdot)\}$ any sequence of W . Define $W^1 = W_{[0, t_1]} = \{x^1 \in C^1([0, t_1], X) \mid x^1(t) = x(t) \text{ for } t \in [0, t_1], x^1(t_1) = x(t_1 - 0), x \in W\}$. By Ascoli-Arzelà Theorem, W^1 is a relatively compact subset of $C^1([0, t_1], X_\alpha)$. Then, there exists a subsequence of $\{x_m\}$, labeled $\{x_m^1\} \subset W$, and $x^1 \in C^1([0, t_1], X_\alpha)$, such that

$$x_m^1 \longrightarrow x^1 \quad \text{in } C^1([0, t_1], X) \text{ as } m \longrightarrow +\infty. \quad (2.14)$$

Define $W^2 = W_{[t_1, t_2]} = \{x^2 \in C^1([t_1, t_2], X) \mid x^2(t) = x(t) \text{ for } t \in (t_1, t_2) \text{ and } x^2(t_1) = x(t_1 + 0), x^2(t_2) = x(t_2 - 0), x \in W\}$. It is not difficult to see that, due to Ascoli-Arzelà Theorem again, W^2 is a relatively compact subset of $C^1([t_1, t_2], X_\alpha)$. There exists a subsequence of $\{x_m^1\}$, labeled $\{x_m^2\} \subset W$, and $x^2 \in C^1([t_1, t_2], X_\alpha)$ such that

$$x_m^2 \longrightarrow x^2 \quad \text{in } C^1([t_1, t_2], X) \text{ as } m \longrightarrow +\infty. \quad (2.15)$$

In general, define $W^i = W_{[t_i, t_{i+1}]} = \{x^i \in C^1([t_i, t_{i+1}], X) \mid x^i(t) = x(t) \text{ for } t \in (t_i, t_{i+1}) \text{ and } x^i(t_i) = x(t_i + 0), x^i(t_{i+1}) = x(t_{i+1} - 0), x \in W\}$ ($i = 2, \dots, n+1$). Similarly, W^i is a relatively compact subset of $C^1([t_i, t_{i+1}], X_\alpha)$. There exists a subsequence of $\{x_m^{i-1}\}$, labeled $\{x_m^i\} \subset W$, and $x^i \in C^1([t_i, t_{i+1}], X)$ such that

$$x_m^i \longrightarrow x^i \quad \text{in } C^1([t_i, t_{i+1}], X) \text{ as } m \longrightarrow +\infty. \quad (2.16)$$

Setting

$$x(t) = \begin{cases} x^1(t), & t \in [0, t_1], \\ x^2(t), & t \in (t_1, t_2], \\ \vdots \\ x^{n+1}(t), & t \in (t_n, T], \end{cases} \quad (2.17)$$

then

$$x_m^{n+1} \longrightarrow x \quad \text{in } PC^1([0, T], X_\alpha) \text{ as } m \longrightarrow +\infty. \quad (2.18)$$

Thus, the set W is a relatively compact set. $\square$

3. Solution of Second-Order Nonlinear Integro-Differential Equations of Mixed Type

We introduce reasonable mild solution for (1.1) and show the existence of PC- α -mild solution.

Definition 3.1. A function $x \in PC^1([0, T], X_\alpha)$ is said to be a PC- α -mild solution of (1.1) if x satisfies the following integral equation:

$$\begin{aligned} x(t) = & x_0 + \int_0^t U(\tau, 0)x_1 d\tau + \int_0^t \int_\tau^t U(s, \tau)f(\tau, x(\tau), \dot{x}(\tau), (Gx)(\tau), (Hx)(\tau))ds d\tau \\ & + \sum_{0 < t_i < t} J_i^0(x(t_i), \dot{x}(t_i)) + \sum_{0 < t_i < t} \int_{t_i}^t U(s, t_i)J_i^1(x(t_i), \dot{x}(t_i))ds. \end{aligned} \quad (3.1)$$

We introduce the following assumptions.

Assumption F. (1) The functions $f : [0, T] \times X_\alpha \times X_\alpha \times X_\alpha \times X_\alpha \rightarrow X$, $g : [0, T] \times X_\alpha \times X_\alpha \rightarrow X_\alpha$, and $h : [0, T] \times X_\alpha \times X_\alpha \rightarrow X_\alpha$ are measurable in $t \in [0, T]$ and locally Lipschitz continuous, that is, for all $x_1, x_2, y_1, y_2, z_1, z_2 \in X_\alpha$, satisfying $\|x_1\|_\alpha, \|x_2\|_\alpha, \|y_1\|_\alpha, \|y_2\|_\alpha, \|z_1\|_\alpha, \|z_2\|_\alpha, \|w_1\|_\alpha, \|w_2\|_\alpha \leq \rho$, we have

$$\begin{aligned} & \|f(t, x_1, y_1, z_1, w_1) - f(t, x_2, y_2, z_2, w_2)\| \\ & \leq L(\rho)(\|x_1 - x_2\|_\alpha + \|y_1 - y_2\|_\alpha + \|z_1 - z_2\|_\alpha + \|w_1 - w_2\|_\alpha), \\ & \|g(t, x_1, y_1) - g(t, x_2, y_2)\|_\alpha \leq L(\rho)(\|x_1 - x_2\| + \|y_1 - y_2\|), \\ & \|h(t, x_1, y_1) - h(t, x_2, y_2)\|_\alpha \leq L(\rho)(\|x_1 - x_2\| + \|y_1 - y_2\|). \end{aligned} \quad (3.2)$$

(2) There exist a constant $0 < \lambda < 1$ and a function $q \in L^r([0, T], [0, +\infty))$ ($r > 1$) such that

$$\begin{aligned} & \|f(t, x, y, z, w)\| \leq q(t)(1 + \|x\|_\alpha + \|y\|_\alpha + \|z\|_\alpha + \|w\|_\alpha), \quad \forall x, y, z, w \in X_\alpha, \\ & \|g(t, x, y)\|_\alpha \leq q(t)(1 + \|x\|_\alpha + \|y\|_\alpha), \quad \forall x, y \in X_\alpha, \\ & \|h(t, x, y)\|_\alpha \leq q(t)(1 + \|x\|_\alpha^\lambda + \|y\|_\alpha^\lambda), \quad \forall x, y \in X_\alpha. \end{aligned} \quad (3.3)$$

(3) $k, m \in C([0, T]^2, R)$.

Assumption J. There exists a constant $b \geq 0$ such that maps $J_i^0 : X_\alpha \times X_\alpha \rightarrow X_\alpha$ and $J_i^1 : X_\alpha \times X_\alpha \rightarrow X_{\beta_i}$ ($0 < \alpha < \beta_i < 1$) satisfy

$$\begin{aligned} & \|J_i^0(x_1, y_1) - J_i^0(x_2, y_2)\|_\alpha \leq b(\|x_1 - x_2\|_\alpha + \|y_1 - y_2\|_{\beta_i}) \quad (i = 1, 2, \dots, n), \\ & \|J_i^1(x_1, y_1) - J_i^1(x_2, y_2)\|_{\beta_i} \leq b(\|x_1 - x_2\|_\alpha + \|y_1 - y_2\|_{\beta_i}) \quad (i = 1, 2, \dots, n). \end{aligned} \quad (3.4)$$

Theorem 3.2. Suppose that $A(0)$ has a compact resolvent, $(x_0, x_1) \in X_\alpha \times X_\beta$, $0 < \alpha < \beta \leq 1$, and $(\alpha + \beta)/2 < (r - 1)/r$. Under the Assumptions A, F and J, the second-order impulsive integro-differential equation (1.1) has a PC- α -mild solution $x \in PC^1([0, T], X_\alpha)$.

Proof. Let $(x_0, x_1) \in X_\alpha \times X_\beta$ be fixed; define the operator P on $PC^1([0, T], X_\alpha)$ given by

$$\begin{aligned} (Px)(t) = & x_0 + \int_0^t U(\tau, 0)x_1 d\tau + \int_0^t \int_\tau^t U(s, \tau)f(\tau, x(\tau), \dot{x}(\tau), (Gx)(\tau), (Hx)(\tau))ds d\tau \\ & + \sum_{0 < t_i < t} J_i^0(x(t_i), \dot{x}(t_i)) + \sum_{0 < t_i < t} \int_{t_i}^t U(s, t_i)J_i^1(x(t_i), \dot{x}(t_i))ds. \end{aligned} \quad (3.5)$$

By virtue of the properties of evolution system $U(\cdot, \cdot)$ and Assumption J, for $t \in [0, T] \setminus \Theta$, we have $(Px)(t) \in X_\alpha$ and

$$\begin{aligned} \frac{d}{dt}(Px)(t) = & U(t, 0)x_1 + \int_0^t U(t, \tau)f(\tau, x(\tau), \dot{x}(\tau), (Gx)(\tau), (Hx)(\tau))d\tau \\ & + \sum_{0 < t_i < t} U(t, t_i)J_i^1(x(t_i), \dot{x}(t_i)). \end{aligned} \quad (3.6)$$

This means that $Px \in PC^1([0, T], X_\alpha)$ for $x \in PC^1([0, T], X_\alpha)$.

For $x, y \in PC^1([0, T], X_\alpha)$ and $\|x\|_{PC^1}, \|y\|_{PC^1} \leq \rho$ in which ρ is a constant. Using Assumptions F(1) and J, we have

$$\begin{aligned} & \|(Px)(t) - (Py)(t)\|_\alpha + \left\| \frac{d}{dt}(Px)(t) - \frac{d}{dt}(Py)(t) \right\|_\alpha \\ & \leq \int_0^t \int_\tau^t \|U(s, \tau)\|_{0, \alpha} \|f(\tau, x(\tau), \dot{x}(\tau), (Gx)(\tau), (Hx)(\tau)) \\ & \quad - f(\tau, y(\tau), \dot{y}(\tau), (Gy)(\tau), (Hy)(\tau))\| ds d\tau \\ & \quad + \int_0^t \|U(t, \tau)\|_{0, \alpha} \|f(\tau, x(\tau), \dot{x}(\tau), (Gx)(\tau), (Hx)(\tau)) \\ & \quad - f(\tau, y(\tau), \dot{y}(\tau), (Gy)(\tau), (Hy)(\tau))\| d\tau \\ & \quad + \sum_{0 < t_i < t} \|J_i^0(x(t_i), \dot{x}(t_i)) - J_i^0(y(t_i), \dot{y}(t_i))\|_\alpha \\ & \quad + \sum_{0 < t_i < t} \int_{t_i}^t \|U(s, t_i)\|_{\beta_i, \alpha} \|J_i^1(x(t_i), \dot{x}(t_i)) - J_i^1(y(t_i), \dot{y}(t_i))\|_{\beta_i} ds \\ & \quad + \sum_{0 < t_i < t} \|U(t, t_i)\|_{\beta_i, \alpha} \|J_i^1(x(t_i), \dot{x}(t_i)) - J_i^1(y(t_i), \dot{y}(t_i))\|_{\beta_i} \end{aligned}$$

$$\begin{aligned}
&\leq C(\alpha, \gamma) L^2(\bar{\rho}) \|m\| T \|x - y\|_{PC^1} \int_0^t \int_\tau^t |s - \tau|^{-\gamma} ds d\tau + C(\alpha, \gamma) L^2(\bar{\rho}) \|m\| T \|x - y\|_{PC^1} \\
&\quad \times \int_0^t |t - \tau|^{-\gamma} d\tau ds + C(\alpha, \gamma) (1 + L(\bar{\rho}))^2 (\|k\| T + 1) \\
&\quad \times \int_0^t \int_\tau^t |s - \tau|^{-\gamma} [\|x(\tau) - y(\tau)\|_\alpha + \|\dot{x}(\tau) - \dot{y}(\tau)\|_\alpha] ds d\tau \\
&\quad + C(\alpha, \gamma) (1 + L(\bar{\rho}))^2 (\|m\| T + 1) \int_0^t \int_\tau^t |s - \tau|^{-\gamma} [\|(x - y)_\tau\|_B + \|(\dot{x} - \dot{y})_\tau\|_B] ds d\tau \\
&\quad + C(\alpha, \gamma) (1 + L(\bar{\rho}))^2 (\|k\| T + 1) \int_0^t |t - \tau|^{-\gamma} [\|x(\tau) - y(\tau)\|_\alpha + \|\dot{x}(\tau) - \dot{y}(\tau)\|_\alpha] d\tau \\
&\quad + C(\alpha, \gamma) (1 + L(\bar{\rho}))^2 (\|m\| T + 1) \int_0^t |t - \tau|^{-\gamma} [\|(x - y)_\tau\|_B + \|(\dot{x} - \dot{y})_\tau\|_B] d\tau \\
&\quad + b \sum_{0 \leq t_i < t} [\|x(t_i) - y(t_i)\|_\alpha + \|\dot{x}(t_i) - \dot{y}(t_i)\|_\alpha] + b(T + 1) \\
&\quad \times \sum_{0 \leq t_i < t} C(\beta_i, \alpha) [\|x(t_i) - y(t_i)\|_\alpha + \|\dot{x}(t_i) - \dot{y}(t_i)\|_\alpha] \\
&\leq \bar{M} \|x - y\|_{PC^1},
\end{aligned} \tag{3.7}$$

where $\alpha < \gamma < 1$,

$$\begin{aligned}
\bar{\rho} &= \rho + 2\|q\|_{L^1} (\rho + \rho^\lambda + 1) (\|k\| + \|m\|), \\
\bar{M} &= 2C(\alpha, \gamma) (L(\bar{\rho}) + 1)^2 (\|k\| T + \|m\| T + 1) \frac{T^{1-\gamma} + T^{2-\gamma}}{1 - \gamma} + b(T + 1) \sum_{i=1}^n (C(\beta_i, \alpha) + 1).
\end{aligned} \tag{3.8}$$

Hence $P : PC^1([0, T], X_\alpha) \rightarrow PC^1([0, T], X_\alpha)$ is a continuous operator.

Let $\mathcal{X} \subseteq PC^1([0, T], X_\alpha)$ be a bounded subset; there exists a constant $\mu > 0$ such that $\|x\|_{PC^1} \leq \mu$ for all $x \in \mathcal{X}$. By Assumption F(2) and the properties of evolution operators, there exists constant $\omega > 0$ such that

$$\|f(t, x(t), \dot{x}(t), (Gx)(t), (Hx)(t))\| \leq \omega q(t), \quad \forall x \in \mathcal{X} \tag{3.9}$$

and $\mathcal{K} = P\mathcal{X}$ is a bounded subset of $PC^1([0, T], X_\alpha)$. Define

$$\mathcal{K}(t) = \{(Px)(t) \mid x \in \mathcal{X}\}, \quad \dot{\mathcal{K}}(t) = \left\{ \frac{d}{dt}(Px)(t) \mid x \in \mathcal{X} \right\} \quad \text{for } t \in [0, T]. \tag{3.10}$$

Clearly, $\mathcal{K}(0) = \{x_0\}$ and $\mathcal{K}(0) = \{x_1\}$ are compact, and hence, it is only necessary to consider $t > 0$. Since $A^{-1}(0)$ is a compact operator, $X_\beta \hookrightarrow X_\alpha$ for $0 \leq \alpha < \beta \leq 1$. For $0 < \varepsilon < t \leq T$, define

$$\begin{aligned}\mathcal{K}_\varepsilon(t) &= \{(P_\varepsilon x)(t) = U(t, t - \varepsilon)(Px)(t - \varepsilon) \mid x \in \mathcal{X}\}, \\ \mathcal{K}_\varepsilon(t) &= \left\{ \frac{d}{dt}(P_\varepsilon x)(t) = U(t, t - \varepsilon) \frac{d}{dt}(Px)(t - \varepsilon) \mid x \in \mathcal{X} \right\}.\end{aligned}\quad (3.11)$$

By the properties of $\{U(t, s) \mid (s, t) \in \bar{\Delta}\}$, one can verify that

$$\begin{aligned}& \|(Px)(t) - (P_\varepsilon x)(t)\|_\alpha \\& \leq \|x_0 - U(t, t - \varepsilon)x_0\|_\alpha + \int_{t-\varepsilon}^t \|U(s, 0)\|_{\beta, \alpha} \|x_1\|_\beta ds \\& \quad + \|I - U(t, t - \varepsilon)\|_{(\alpha+\beta)/2, \alpha} \int_0^{t-\varepsilon} \|U(s, 0)\|_{\beta, (\alpha+\beta)/2} \|x_1\|_\beta ds \\& \quad + \int_{t-\varepsilon}^t \int_\tau^t \|U(s, \tau)\|_{0, \alpha} \|f(\tau, x(\tau), \dot{x}(\tau), (Gx)(\tau), (Hx)(\tau))\| ds d\tau \\& \quad + \int_0^{t-\varepsilon} \int_{t-\varepsilon}^t \|U(s, \tau)\|_{0, \alpha} \|f(\tau, x(\tau), \dot{x}(\tau), (Gx)(\tau), (Hx)(\tau))\| ds d\tau \\& \quad + \|I - U(t, t - \varepsilon)\|_{(\alpha+\beta)/2, \alpha} \\& \quad \times \int_0^{t-\varepsilon} \int_\tau^{t-\varepsilon} \|U(s, \tau)\|_{0, (\alpha+\beta)/2} \|f(\tau, x(\tau), \dot{x}(\tau), (Gx)(\tau), (Hx)(\tau))\| ds d\tau \\& \leq \|x_0 - U(t, t - \varepsilon)x_0\|_\alpha + C(\beta, \alpha) \|x_1\|_\beta \varepsilon + C\left(\frac{\alpha + \beta}{2}, \alpha, \gamma_1\right) C\left(\beta, \frac{\alpha + \beta}{2}\right) \|x_1\|_\beta \varepsilon^{\gamma_1} \\& \quad + \frac{\omega C(\alpha, \gamma)}{1 - \gamma} \|q\|_{L^r} \left(\frac{r-1}{r(2-\gamma)-1}\right)^{(r-1)/r} \varepsilon^{(r(2-\gamma)-1)/r} \\& \quad + \omega \|q\|_{L^r} C(\alpha, \gamma) \left(\frac{r-1}{r-r\gamma-1}\right)^{(r-1)/r} T^{(r-r\gamma-1)/r} \varepsilon \\& \quad + \omega \|q\|_{L^r} C\left(\frac{\alpha + \beta}{2}, \alpha, \gamma_1\right) C\left(\frac{\alpha + \beta}{2}, \gamma_2\right) \left(\frac{r-1}{r-1-r\gamma_2}\right)^{(r-1)/r} T^{(2r-1-\gamma_2)/r} \varepsilon^{\gamma_1},\end{aligned}\quad (3.12)$$

where $0 < \gamma_1 < (\beta - \alpha)/2$, $(\alpha + \beta)/2 < \gamma_2 < 1$, and

$$\left\| \frac{d}{dt}(Px)(t) - \frac{d}{dt}(P_\varepsilon x)(t) \right\|_\alpha \leq \omega \|q\|_{L^r} C(\alpha, \gamma) \frac{r-1}{r-1-r\gamma} \varepsilon^{(r-1-r\gamma)/(r-1)}, \quad x \in \mathcal{X}. \quad (3.13)$$

This means that the set $\mathcal{K}(t)(\mathcal{K}(t))$ can be approximated to an arbitrary degree of accuracy by a relatively compact set for $t \in (0, t_1]$. Hence $\mathcal{K}(t)(\mathcal{K}(t))$ itself is relatively compact in X_α for $t \in (0, t_1]$. Define

$$\begin{aligned}\mathcal{K}(t_1 + 0) &= \left\{ (Px)(t)|_{t=t_1} + J_1^0 \left((Px)(t_1), \frac{d}{dt} (Px)(t)|_{t=t_1} \right) \right\}, \\ \mathcal{K}(t_1 + 0) &= \left\{ \frac{d}{dt} (Px)(t)|_{t=t_1} + J_1^1 \left((Px)(t_1), \frac{d}{dt} (Px)(t)|_{t=t_1} \right) \right\}.\end{aligned}\quad (3.14)$$

Using relative compactness of $\mathcal{K}(t)$ and $\dot{\mathcal{K}}(t)$ ($t \in [0, t_1]$) and Assumption J, one can show that $\mathcal{K}(t_1 + 0)$ and $\dot{\mathcal{K}}(t_1 + 0)$ are relative compacts in X_α .

By the same procedure, the compactness of $\dot{\mathcal{K}}(t)$ and $\mathcal{K}(t)$ ($t \in [0, T]$) can also be proved.

Further, using representations of $(Px)(t)$ and $(d/dt)(Px)(t)$, properties of $\{\bar{U}(t, s), 0 \leq s \leq t \leq T\}$ (see Theorem 2.1), and those above, one can show that Px is piecewise equicontinuous. Summarily, P is a compact operator in $PC^1([0, T], X_\alpha)$.

By virtue of Gronwall inequality (see Theorem 2.2), one can verify that $\mathcal{Y} = \{x \in PC^1([0, T], X_\alpha) \mid x = \delta Px, \delta \in [0, 1]\}$ is a bounded subset of $PC^1([0, T], X_\alpha)$. According to Leray-Schauder fixed point theorem, P has a fixed point in $PC^1([0, T], X_\alpha)$. It can be given by the representation (3.1) and $x(t) \in D(A)$ for $t \in [0, T]$. $\square$

Remark 3.3. Similarly, under suitable assumptions, the following second-order nonlinear impulsive integro-differential equation of mixed type

$$\begin{aligned}\ddot{x}(t) + A(t)\dot{x}(t) &= f(t, x(t), \dot{x}(t), (Gx)(t), (Hx)(t)), \quad t \in (0, T] \setminus (\Theta \cup \Lambda), \\ x(0) &= x_0, \quad \Delta x(t_i) = J_i^0(x(t_i), \dot{x}(t_i)), \quad t_i \in \Theta, \quad i = 1, 2, \dots, n, \\ \dot{x}(0) &= x_1, \quad \Delta \dot{x}(s_j) = J_j^1(x(s_j), \dot{x}(s_j)), \quad s_j \in \Lambda, \quad j = 1, 2, \dots, m,\end{aligned}\quad (3.15)$$

has a PC- α -mild solution $x \in PC^1([0, T], X_\alpha)$ given by

$$\begin{aligned}x(t) &= x_0 + \int_0^t U(\tau, 0)x_1 d\tau + \int_0^t \int_\tau^s U(s, \tau)f(\tau, x(\tau), \dot{x}(\tau), (Gx)(\tau), (Hx)(\tau)) ds d\tau \\ &\quad + \sum_{0 < t_i < t} J_i^0(x(t_i), \dot{x}(t_i)) + \sum_{0 < s_j < t} \int_{s_{ji}}^t U(s, s_j) J_j^1(x(s_j), \dot{x}(s_j)) ds.\end{aligned}\quad (3.16)$$

Remark 3.4. Assume that $A(0)$ has a compact resolvent, $(x_0, x_1) \in X_\alpha \times X_\beta$, $0 < \alpha < \beta \leq 1$, and $(\alpha + \beta)/2 < (r - 1)/r$.

Under the Assumptions A and F, the second-order nonlinear integro-differential equation of mixed type

$$\begin{aligned}\ddot{x}(t) + A(t)\dot{x}(t) &= f(t, x(t), \dot{x}(t), (Gx)(t), (Hx)(t)), \quad t \in (0, T], \\ x(0) &= x_0, \quad \dot{x}(0) = x_1\end{aligned}\quad (3.17)$$

has a unique α -mild solution $x \in PC^1([0, T], X_\alpha)$ given by

$$x(t) = x_0 + \int_0^t U(\tau, 0)x_1 d\tau + \int_0^t \int_\tau^s U(s, \tau)f(\tau, x(\tau), \dot{x}(\tau), (Gx)(\tau), (Hx)(\tau))ds d\tau. \quad (3.18)$$

4. Existence of Optimal Controls

We suppose that Y is a reflexive Banach space from which the controls u take the values. We denote a class of nonempty closed and convex subsets of Y by $P_f(Y)$. Assume that the multifunction $\omega : [0, T] \rightarrow P_f(Y)$ is measurable and $\omega(\cdot) \subset E$ where E is a bounded set of Y , the admissible control set $U_{ad} = \{u \in L_p(E) \mid u(t) \in \omega(t) \text{ a.e}\} \neq \emptyset$ (see [18, Proposition 1.7, page 142, Lemma 3.2, page 175]).

Consider the following controlled system:

$$\begin{aligned} \ddot{x}(t) + A(t)\dot{x}(t) &= f(t, x(t), \dot{x}(t), (Gx)(t), (Hx)(t)) + B(t)u(t), \quad t \in (0, T] \setminus \Theta, \\ x(0) &= x_0, \quad \Delta x(t_i) = J_i^0(x(t_i), \dot{x}(t_i)), \quad t_i \in \Theta, \quad i = 1, 2, \dots, n, \\ \dot{x}(0) &= x_1, \quad \Delta \dot{x}(t_i) = J_i^1(x(t_i), \dot{x}(t_i)), \quad t_i \in \Theta, \quad i = 1, 2, \dots, n. \end{aligned} \quad (4.1)$$

Assumption B. $B \in L_\infty([0, T], \mathcal{L}(Y, X))$.

It is easy to see that $Bu \in L_p([0, T], X)$ for all $u \in U_{ad}$. Define $\mathcal{F}(t, x(t), \dot{x}(t), (Gx)(t), (Hx)(t)) = f(t, x(t), \dot{x}(t), (Gx)(t), (Hx)(t)) + B(t)u(t)$. It is obvious that $\mathcal{F}$ satisfies the Assumption F.

Theorem 4.1. Suppose $A(0)$ has a compact resolvent. Under Assumptions A, B, F, and J, for every $u \in U_{ad}$, the system (4.1) has a PC- α -mild solution corresponding to u provided $0 < (\alpha + \beta)/2, \beta < \min\{(p-1)/p, (r-1)/r\}$.

Define $\mathcal{T} = \{(x, u) \in PC^1([0, T], X_\alpha) \times U_{ad} \mid x \text{ as a PC-}\alpha\text{-mild solution of system (4.1) corresponding to the control } u \in U_{ad}\}$. $(x, u) \in \mathcal{T}$ is called a feasible pair. We consider the Lagrange problem (P).

Find $(x^0, u^0) \in \mathcal{T}$ such that

$$J(x^0, u^0) \leq J(x, u), \quad \forall (x, u) \in \mathcal{T}, \quad (4.2)$$

where

$$J(x, u) = \int_0^T l(t, x(t), \dot{x}(t), u(t))dt. \quad (4.3)$$

We introduce some assumptions on l .

Assumption L. (1) The functional $l : [0, T] \times X_\alpha \times X_\alpha \times Y \rightarrow R \cup \infty$ is Borel measurable.

(2) $l(t, \cdot, \cdot, \cdot)$ is sequentially lower semicontinuous on $X_\alpha \times X_\alpha \times Y$ for almost all $t \in [0, T]$.

- (3) $l(t, x, y, \cdot)$ is convex on Y for each $(x, y) \in X_\alpha \times X_\alpha$ and almost all $t \in [0, T]$.
 (4) There exist constants $b \geq 0, c \geq 0, \varpi > 0$, and $\varphi \in L_1([0, T], R)$ such that

$$l(t, x, y, u) \geq \varphi(t) + b\|x\|_\alpha + c\|y\|_\alpha + \varpi\|u\|_Y^p, \quad \forall x, y \in X_\alpha, u \in Y. \quad (4.4)$$

Now we can give the following result on the existence of optimal controls for problem (P).

Theorem 4.2. *Under assumptions of Theorem 4.1 and assumption L, the problem (P) has a solution.*

Proof. If $\inf\{J(x, u) \mid u \in U_{\text{ad}}\} = +\infty$, there is nothing to prove. Assume that $\inf\{J(x, u) \mid u \in U_{\text{ad}}\} = m < +\infty$. By Assumption L, we have $m > -\infty$. By definition of infimum, there exists a sequence $\{u^n\} \subset U_{\text{ad}}$ such that $J(x^n, u^n) \rightarrow m$. Since $\{u^n\}$ is bounded in $L_p([0, T], Y)$, there exists a subsequence, relabeled as $\{u^n\}$, and $u^0 \in L_p([0, T], Y)$ such that

$$u^n \xrightarrow{w} u^0 \quad \text{in } L_p([0, T], Y). \quad (4.5)$$

Since U_{ad} is closed and convex, from the Mazur Lemma, we have $u^0 \in U_{\text{ad}}$.

Suppose x^n is the PC- α -mild solution of (4.1) corresponding to u^n ($n = 0, 1, 2, \dots$). Then x^n satisfies the following impulsive integral equation:

$$\begin{aligned} x^n(t) &= x_0 + \int_0^t U(\tau, 0)x_1 d\tau \\ &+ \int_0^t \int_0^s U(s, \tau) [f(\tau, x^n(\tau), \dot{x}^n(\tau), (Gx^n)(\tau), (Hx^n)(\tau)) + B(\tau)u^n(\tau)] d\tau ds \\ &+ \sum_{0 < t_i < t} J_i^0(x^n(t_i), \dot{x}^n(t_i)) + \sum_{0 < t_i < t} \int_{t_i}^t U(s, t_i) J_i^1(x^n(t_i), \dot{x}^n(t_i)) ds. \end{aligned} \quad (4.6)$$

Setting $F_n(t) = f(t, x^n(t), \dot{x}^n(t), (Gx^n)(t), (Hx^n)(t))$, by Assumptions F(2) and J, and Lemma 3.1, we obtain that $F_n \in \mathcal{L}_r([0, T], X)$ ($r > 1$). Furthermore, there exists a subsequence, relabeled as $\{F_n\}$, and $\bar{F} \in L_r([0, T], X)$ such that $F_n \xrightarrow{w} \bar{F}$ in $L_r([0, T], X)$ as $n \rightarrow \infty$.

Define operators $Q : L_r([0, T], X) \rightarrow C([0, T], X)$, given by

$$(Qy)(t) = \int_0^t U(t, s)y(s)ds. \quad (4.7)$$

By [7, Lemma 4.1], we have

$$QF_n \longrightarrow Q\bar{F} \quad \text{in } C([0, T], X) \text{ as } n \longrightarrow \infty. \quad (4.8)$$

Consider the following impulsive differential equation:

$$\begin{aligned}\ddot{x}(t) + A(t)\dot{x}(t) &= \bar{F}(t) + B(t)u^0(t), \quad t \in (0, T] \setminus \Theta, \\ x(0) &= x_0, \quad \Delta x(t_i) = J_i^0(x(t_i), \dot{x}(t_i)), \quad t_i \in \Theta, \quad i = 1, 2, \dots, n, \\ \dot{x}(0) &= x_1, \quad \Delta \dot{x}(t_i) = J_i^1(x(t_i), \dot{x}(t_i)), \quad t_i \in \Theta, \quad i = 1, 2, \dots, n.\end{aligned}\tag{4.9}$$

By Theorem 3.2, we know that (4.9) have a PC- α -mild solution

$$\begin{aligned}\bar{x}(t) &= x_0 + \int_0^t U(\tau, 0)x_1 d\tau + \int_0^t \int_0^s U(s, \tau) [\bar{F}(\tau) + B(\tau)u^0(\tau)] d\tau ds \\ &\quad + \sum_{0 < t_i < t} J_i^0(\bar{x}(t_i), \dot{\bar{x}}(t_i)) + \sum_{0 < t_i < t} \int_{t_i}^t U(s, t_i) J_i^1(\bar{x}(t_i), \dot{\bar{x}}(t_i)) ds.\end{aligned}\tag{4.10}$$

Define

$$\eta_n(t) = \int_0^t U(t, \tau) [F_n(\tau) - \bar{F}(\tau) + B(\tau)u^n(\tau) - B(\tau)u^0(\tau)] d\tau,\tag{4.11}$$

then, $\eta_n \rightarrow 0$ in $C([0, T], X_\alpha)$ as $n \rightarrow \infty$. Using Assumption J, we obtain

$$\begin{aligned}\|x^n(t) - \bar{x}(t)\|_\alpha + \|\dot{x}^n(t) - \dot{\bar{x}}(t)\|_\alpha \\ \leq (T+1)\|\eta_n\|_{C([0, T], X_\alpha)} + b(T+1) \sum_{0 < t_i < t} (C(\beta_i, \alpha) + 1) (\|x^n(t_i) - \bar{x}(t_i)\|_\alpha + \|\dot{x}^n(t_i) - \dot{\bar{x}}(t_i)\|_\alpha).\end{aligned}\tag{4.12}$$

Using the Gronwall lemma with impulse (see [17, Lemma 1.7.1]), we have

$$\|x^n(t) - \bar{x}(t)\|_\alpha + \|\dot{x}^n(t) - \dot{\bar{x}}(t)\|_\alpha \leq b(T+1)^2 \prod_{i=1}^n (C(\beta_i, \alpha) + 1) \|\eta_n\|_{C([0, T], X)},\tag{4.13}$$

that is, $x^n \rightarrow \bar{x}$ in $PC^1([0, T], X_\alpha)$ as $n \rightarrow \infty$. Further,

$$F_n(\cdot) \longrightarrow f\left(\cdot, \bar{x}(\cdot), \dot{\bar{x}}(\cdot), (G\bar{x})(\cdot), (H\bar{x})(\cdot)\right) \quad \text{in } L_r([0, T], X) \text{ as } n \longrightarrow \infty.\tag{4.14}$$

By the uniqueness of limit, we have

$$\bar{F}(t) = f\left(t, \bar{x}(t), \dot{\bar{x}}(t), (G\bar{x})(t), (H\bar{x})(t)\right),\tag{4.15}$$

Furthermore,

$$\begin{aligned}\bar{x}(t) &= x_0 + \int_0^t U(\tau, 0)x_1 d\tau \\ &+ \int_0^t \int_0^s U(s, \tau) \left[f\left(\tau, \bar{x}(\tau), \dot{\bar{x}}(\tau), (G\bar{x})(\tau), (H\bar{x})(\tau)\right) + B(\tau)u^0(\tau) \right] d\tau ds \\ &+ \sum_{0 < t_i < t} J_i^0\left(\bar{x}(t_i), \dot{\bar{x}}(t_i)\right) + \sum_{0 < t_i < t} \int_{t_i}^t U(s, t_i) J_i^1\left(\bar{x}(t_i), \dot{\bar{x}}(t_i)\right) ds.\end{aligned}\quad (4.16)$$

Thus, $\bar{x}$ is a PC- α -mild solution of (4.1) corresponding to u^0 .

Since $PC^1([0, T], X_\alpha) \hookrightarrow L_1([0, T], X_\alpha)$, using the Assumption L, we can obtain

$$m = \lim_{n \rightarrow \infty} \int_0^T l(t, x^n(t), \dot{x}^n(t), u^n(t)) dt \geq \int_0^T l(t, \bar{x}(t), \dot{\bar{x}}(t), u^0(t)) dt = J(\bar{x}, u^0) \geq m. \quad (4.17)$$

This means that J attains its minimum at $u^0 \in U_{ad}$. $\square$

At the end of this section, an example is given to illustrate our theory. We consider the following problem:

$$\begin{aligned}&\ddot{x}(t, y) + (t+1)\Delta \dot{x}(t, y) \\ &= \dot{x}(t, y) + x(t, y) + \int_0^t (t-\tau) \sqrt{x^2(\tau, y) + \dot{x}^2(\tau, y) + 1} d\tau \\ &+ \int_0^1 (t+\tau)^2 \sqrt{x^2(\tau, y) + \dot{x}^2(\tau, y) + 1} d\tau \\ &+ u(t, y), \quad y \in \Omega, \quad t \in (0, 1] \setminus \left\{ \frac{1}{10}, \frac{2}{10}, \dots, \frac{9}{10} \right\}, \\ &x(t, y)|_{[0,1] \times \partial\Omega} = 0, \quad x(0, y) = 0, \quad \frac{\partial}{\partial t} x(t, y)|_{[0,1] \times \partial\Omega} = 0, \quad \frac{\partial}{\partial t} x(t, y)|_{t=0} = 0, \quad y \in \Omega, \\ &x\left(\frac{i}{10} + 0, y\right) - x\left(\frac{i}{10} - 0, y\right) = \frac{1}{2}x\left(\frac{i}{10} - 0, y\right), \quad i = 1, \dots, 9, \\ &\dot{x}\left(\frac{i}{10} + 0, y\right) - \dot{x}\left(\frac{i}{10} - 0, y\right) = \frac{1}{2}\dot{x}\left(\frac{i}{10} - 0, y\right), \quad i = 1, 2, \dots, 9,\end{aligned}\quad (4.18)$$

where $\ddot{x}(t, y) = (\partial^2 / \partial t^2)x(t, y)$, $\dot{x}(t, y) = (\partial / \partial t)x(t, y)$, $\Omega \subset \mathbb{R}^3$ is bounded domain, and $\partial\Omega \in C^3$.

Define $X = Y = L^2(\Omega)$, $D(A(t)) = H^2(\Omega) \cap H_0^1(\Omega)$, and $A(t)x = (t+1)(\partial^2 x / \partial y_1^2 + \partial^2 x / \partial y_2^2 + \partial^2 x / \partial y_3^2)$ for $x \in D(A(t))$; U_{ad} is a nonempty bounded closed subset of Y . Let

$$J(u) = \int_0^1 \int_\Omega |x(t, \xi)|^2 d\xi dt + \int_0^1 \int_\Omega \left| \frac{\partial}{\partial t} x(t, \xi) \right|^2 d\xi dt + \int_0^1 \int_\Omega |u(t, \xi)|^2 d\xi dt. \quad (4.19)$$

Define $V(\cdot)[u(\cdot)](y) = u(\cdot, y)$, $[x(\cdot)](y) = x(\cdot, y)$, $[(Gx)(\cdot)](y) = \int_0^{\cdot} (\cdot - \tau) \sqrt{x^2(\tau, y) + \dot{x}^2(\tau, y) + 1} d\tau$, $[(Hx)(\cdot)](y) = \int_0^1 (\cdot + \tau)^2 \sqrt{x^2(\tau, y) + \dot{x}^2(\tau, y) + 1} d\tau$, $[F(\cdot, x(\cdot), \dot{x}(\cdot), (Gx)(\cdot), (Hx)(\cdot))](y) = \int_0^{\cdot} (\cdot - \tau) \sqrt{x^2(\tau, y) + \dot{x}^2(\tau, y) + 1} d\tau + \int_0^1 (\cdot + \tau)^2 \sqrt{x^2(\tau, y) + \dot{x}^2(\tau, y) + 1} d\tau + x(\cdot, y) + \dot{x}(\cdot, y)$, $[g_i^0(x(i/10))](y) = 1/2x(i/10, y)$, $[g_i^1(\dot{x}(i/10))](y) = (1/2)\dot{x}(i/10, y)$; then F satisfies Assumption F. Thus the problem (4.18) can be rewritten as

$$\begin{aligned} \ddot{x}(t) + A(t)\dot{x}(t) &= F(t, x(t), \dot{x}(t), (Gx)(t), (Hx)(t)) + V(t)u(t), \quad t \in (0, 1] \setminus \left\{ \frac{1}{10}, \dots, \frac{9}{10} \right\}, \\ x(0) &= 0, \quad x\left(\frac{i}{10}+\right) - x\left(\frac{i}{10}-\right) = g_i^0\left(x\left(\frac{i}{10}\right)\right), \quad i = 1, 2, \dots, 9, \\ \dot{x}(0) &= 0, \quad \dot{x}\left(\frac{i}{10}+\right) - \dot{x}\left(\frac{i}{10}-\right) = g_i^1\left(\dot{x}\left(\frac{i}{10}\right)\right), \quad i = 1, 2, \dots, 9, \end{aligned} \quad (4.20)$$

with the cost function

$$J(u) = \int_0^1 \left(\|x(t)\|_X^2 + \|\dot{x}(t)\|_X^2 + \|u(t)\|_X^2 \right) dt. \quad (4.21)$$

Obviously, satisfying all the assumptions given in our former Theorem 4.2, our results can be used in (4.20).
