A class of dynamical neural network models with time-varying delays is considered. By employing the Lyapunov-Krasovskii functional method and linear matrix inequalities (LMIs) technique, some new sufficient conditions ensuring the input-to-state stability (ISS) property of the nonlinear network systems are obtained. Finally, numerical examples are provided to illustrate the efficiency of the derived results.

1. Introduction

Recently, the dynamical neural networks (DNNs), which are firstly introduced by Hopfield in [1], have been extensively studied due to its wide applications in various areas such as associative memory, parallel computation, signal processing, optimization, and moving object speed detection. Since time delay is inevitably encountered in implementation of DNNs and is frequently a source of oscillation and instability, neural networks with time delays have become a topic of great theoretical and practical importance, and many interesting results have been derived (see, e.g., [2–5] and [6–9]). Furthermore, in practical evolutionary processes of the networks, absolute constant delay may be scarce and is only the poetic approximation of the time-varying delays. Delays are generally varied with time because information transmission from one neuron to another neuron may make the response of networks with time-varying delays. Accordingly, dynamical behaviors of neural networks with time-varying delays have been discussed in the last decades (see, e.g., [3, 8–11], etc.).

It is well known that neural networks are often influenced by external disturbances and input errors. Thus many dissipative properties such as robustness [12], passivity [13], and input-to-state stability [4, 10, 11, 14–19] are apparently significant to analyze its

dynamical behaviors of the networks. For instance, Ahn incorporated robust training law in switched Hopfield neural networks with external disturbances to study boundedness and exponentially stability [12], and studied passivity in [13]. Especially, the ISS implies not only that the unperturbed system is asymptotically stable in the Lyapunov sense but also that its behavior remains bounded when its inputs are bounded. It is one of the useful classes of dissipative properties for nonlinear systems, which is firstly introduced in nonlinear control systems by Sontag in [20], and then extended by Praly and Jiang [21] and Angeli et al. [19 and Ahn (see [17, 19], and references therein). Due to these research background, the ISS properties of neural networks are investigated in recent years (see, e.g., [16–19] and references therein). For example, by using the Lyapunov function method, some nonlinear feedback matrix norm conditions for ISS have been developed for recurrent neural networks ([16]). Moreover, Ahn utilized Lyapunov function method to discuss robust stability problem for a class of recurrent neural networks, and also some LMI sufficient conditions have been proposed to guarantee the ISS (see [17]). In [18], by employing a suitable Lyapunov function, some results on boundedness, ISS, and convergence are established. Also, in [19] a new sufficient condition is derived to guarantee ISS of Takagi-Sugeno fuzzy Hopfield neural networks with time delay. However, there is few results to deal with the ISS of dynamical neural networks (DNNs) with time-varying delays ([11]).

Motivated by the above discussions, we discuss the ISS properties of DNNs with time-varying delays in this paper. By using Lyapunov-Krasovskii functional technique, ISS conditions for the considered dynamical neural networks are given in terms of LMIs, which can be easily calculated by certain standard numerical packages. We also provide two illustrative examples to demonstrate the effectiveness of the proposed stability results.

The organization of this paper is as follows. In Section 2, our mathematical model of dynamical neural networks is presented and some preliminaries are given. In Section 3, the main results for both ISS and asymptotically stability of dynamical neural networks with time-varying delays are proposed. In Section 4, two numerical examples are illustrated to demonstrate the effectiveness of the theoretical results. Concluding remarks are collected in Section 5. Proof of Lemma 2.4 is given in the appendix.

Notions

Let R^n denote the n -dimensional Euclidean space and $|\cdot|$ denote the usual Euclidean norm. Denote $C = C([- \tau, 0], R^n)$ and designate the norm of an element in C by $\|\phi\|_\tau = \sup_{-\tau \leq \theta \leq 0} \|\phi(\theta)\|$. $R^{n \times n}$ is the set of all $n \times n$ real matrices. Let B^T , B^{-1} , $\lambda_{\max}(B)$, $\lambda_{\min}(B)$, and $\|B\| = \sqrt{\lambda_{\max}(B^T B)}$ denote the transpose, the inverse, the largest eigenvalue, the smallest eigenvalue, and the Euclidean norm of a square matrix B , respectively. The notation $P > 0$ (≥ 0) means that P is real symmetric and positive definite (positive semidefinite). The notion $X > Y$ ($X \geq Y$), where X and Y are symmetric matrices, means that $X - Y$ is positive definite (positive semidefinite). I denotes the element matrix. The set of all measurable locally essentially bounded functions $u : R^+ \rightarrow R^n$, endowed with (essential) supremum norm $\|u\|_\infty = \sup\{\|u(t)\|, t \geq 0\}$, is denoted by L_∞^m . In addition, denote u_t the truncation of u at t ; that is, $u_t(s) = u(s)$ if $s \leq t$, and $u_t(s) = 0$ if $s > t$. We recall that a function $\gamma : R^+ \rightarrow R^+$ is a K -function if it is continuous, strictly increasing, and $\gamma(0) = 0$; it will be a K_∞ -function if it is a K -function and also $\gamma(s) \rightarrow \infty$ as $s \rightarrow \infty$. A function $\beta : R^+ \times R^+ \rightarrow R^+$ is a KL -function if for each fixed $t \geq 0$ the function $\beta(\cdot, t)$ is a K -function, and, for each fixed $s \geq 0$, it is decreasing to zero as $t \rightarrow \infty$.

2. Mathematical Model and Preliminaries

Consider the following nonlinear time-delay system

$$\dot{x} = f(t, x_t, u(t)), \quad (2.1)$$

where $x(t) \in R^n$ is the state vector, $u(t) \in R^n$ is the input function; $x_t \in C$ is the standard function given by $x_t(\tau) = x(t + \tau)$. Without loss of generality, we suppose that $f(0, 0, 0) = 0$, which ensuring that $x(t) = 0$ is the trivial solution for the unforced system $\dot{x}(t) = f(t, x_t, 0)$. Define $x(t) \triangleq x(t, t_0, \phi)$ is a solution of system with initial value ϕ at time t_0 .

Given a continuous functional $V : R^+ \times C \rightarrow R^+$, the upper right-hand derivative $\dot{V}$ of the function V is given by

$$\dot{V}(t, \phi) = \limsup_{h \rightarrow 0^+} \frac{1}{h} [V(t + h, x_{t+h}(t, x_t)) - V(t, x_t)]. \quad (2.2)$$

For delayed dynamical system, we first give the input-to-state stable (ISS) definition as usual case.

Definition 2.1. System (2.1) is ISS if there exist a KL -function β and a K -function γ such that, for each input $u \in L_\infty^m$ and each $\xi_{t_0} \in C$, it satisfies

$$|x(t; \xi, u)| \leq \beta(\|\xi_{t_0}\|_\tau, t - t_0) + \gamma(\|u_t\|_\infty), \quad \forall t \geq t_0. \quad (2.3)$$

Note that, by causality, the same definition would result if one could replace $\|u_t\|_\infty$ by $\|u\|_\infty$.

Definition 2.2. A continuous differentiable functional $V(t, \phi) : R^+ \times C \rightarrow R^+$ is called the ISS Lyapunov-Krasovskii functional if there exist functions α_1, α_2 of class K_∞ , a function χ of class K and a continuous positive definite function W such that

$$\alpha_1(|\phi(0)|) \leq V(t, \phi) \leq \alpha_2(\|\phi\|_\tau), \quad (2.4)$$

$$\dot{V}(t, \phi) \leq -W(|\phi(0)|) \quad \text{if } |\phi(0)| \geq \chi(\|u\|_\infty), \quad \forall \phi \in C, u \in L_\infty^m. \quad (2.5)$$

Remark 2.3. A continuous differential functional $V(t, \phi) : R^+ \times C \rightarrow R^+$ is an ISS Lyapunov-Krasovskii functional if and only if there exist $\alpha_3, \alpha_4 \in K_\infty$ such that (2.4) holds and

$$\dot{V}(t, \phi) \leq -\alpha_3(|\phi(0)|) + \alpha_4(\|u\|_\infty). \quad (2.6)$$

The proof is similarly to one of Remark 2.4 in [23]. We omit it here.

Similarly to the case of ordinary differential equation (ODE), we will establish a link between the ISS property and the ISS Lyapunov-Krasovskii functional for time-delay systems in the following Lemma.

Lemma 2.4. *The system (2.1) is ISS if it admits an ISS Lyapunov-Krasovskii functional.*

For completeness, the proof is given in appendix.

To obtain our results, we need the following two useful lemmas.

Lemma 2.5 (Schur Complement [24]). *For given symmetric matrix $S = \begin{pmatrix} S_{11} & S_{12} \\ S_{21} & S_{22} \end{pmatrix}$, where $S_{11} \in R^{r \times r}$, $S_{21} = S_{12}^T$, the following three conditions are equivalent:*

- (i) $S < 0$;
- (ii) $S_{11} < 0, S_{22} - S_{12}^T S_{11}^{-1} S_{12}$;
- (iii) $S_{22} < 0, S_{11} - S_{12} S_{22}^{-1} S_{12}^T$.

Lemma 2.6 (see [25]). *Given any matrix X, Y , and Λ with appropriate dimensions such that $\Lambda = \Lambda^T$ and any scalar $\varepsilon > 0$, then*

$$X^T Y + Y^T X \leq \varepsilon X^T \Lambda X + \frac{1}{\varepsilon} Y^T \Lambda^{-1} Y. \quad (2.7)$$

In this paper, we consider the following dynamical neural networks with time-varying delays

$$\frac{dx_i(t)}{dt} = -a_i x_i(t) + \sum_{j=1}^n b_{ij} g_j(x_j(t)) + \sum_{j=1}^n c_{ij} g_j(x_j(t - \tau(t))) + \sum_{i=1}^n u_i(t), \quad i = 1, 2, \dots, n, \quad (2.8)$$

or equivalently

$$\frac{dx(t)}{dt} = -Ax(t) + Wg(x(t)) + W_1 g(x(t - \tau(t))) + u(t), \quad (2.9)$$

where $x(t) = (x_1(t), x_2(t), \dots, x_n(t))^T$ is the neuron state, $u(t) = (u_1(t), u_2(t), \dots, u_n(t))^T$ is the input, and $g(x(t)) = (g_1(x_1(t)), g_2(x_2(t)), \dots, g_n(x_n(t)))^T$ denotes the nonlinear neuron activation function. $A = \text{diag}\{a_1, a_2, \dots, a_n\}$ is the positive diagonal matrix. $W = (b_{ij})_{n \times n}$ and $W_1 = (c_{ij})_{n \times n}$ are the interconnection matrices representing the weighting coefficients of neurons. $\tau(t)$ is the time-varying delays.

Throughout this paper, we always suppose that

$$|g_i(x_i(t))| \leq l_i |x_i|, \quad \forall i, \forall x_i \in R, i = 1, 2, \dots, n, \quad (A1)$$

$$0 \leq \tau(t) \leq \tau, \quad 0 \leq \dot{\tau}(t) \leq 1. \quad (A2)$$

From (A1), we easily see that $x(t) = 0$ is the solution of (2.9) with $u(t) = 0$.

3. ISS Analysis

In this section, we give two theorems on ISS in form of LMIs.

Theorem 3.1. *Let (A1) and (A2) hold. If there exist a positive definite matrix P and a positive diagonal matrix D such that*

$$\begin{pmatrix} -A^T P - PA & M & I & PW_1 \\ M & D^{-2} + W^T P W & 0 & 0 \\ I & 0 & P & 0 \\ W_1^T P & 0 & 0 & -D^{-2} \end{pmatrix} < 0, \quad (3.1)$$

where $M = \text{diag}\{l_1, l_2, \dots, l_n\}$, and then the system (2.9) is ISS.

Proof. We consider the following functional:

$$V(x(t)) = x^T(t) P x(t) + \int_{t-\tau(t)}^t g^T(x(\zeta)) D^{-2} g(x(\zeta)) d\zeta. \quad (3.2)$$

Its derivative along the solution $x(t)$ of (2.9) is given as

$$\begin{aligned} \dot{V}(x(t)) &= 2x^T(t) P \dot{x}(t) + g^T(x(t)) D^{-2} g(x(t)) \\ &\quad - (1 - \dot{\tau}(t)) g^T(x(t - \tau(t))) D^{-2} g(x(t - \tau(t))) \\ &= 2x^T(t) P [-Ax(t) + Wg(x(t)) + W_1 g(x(t - \tau(t))) + u(t)] \\ &\quad + g^T(x(t)) D^{-2} g(x(t)) - (1 - \dot{\tau}(t)) g^T(x(t - \tau(t))) D^{-2} g(x(t - \tau(t))) \\ &= 2x^T(t) (-A^T P - PA) x(t) + 2x^T(t) P W g(x(t)) \\ &\quad + 2x^T(t) P W_1 g(x(t - \tau(t))) + g^T(x(t)) D^{-2} g(x(t)) \\ &\quad - (1 - \dot{\tau}(t)) g^T(x(t - \tau(t))) D^{-2} g(x(t - \tau(t))) + 2x^T(t) P u(t). \end{aligned} \quad (3.3)$$

We have

$$\begin{aligned} &- (1 - \dot{\tau}(t)) g^T(x(t - \tau(t))) D^{-2} g(x(t - \tau(t))) + 2x^T(t) P W_1 g(x(t - \tau(t))) \\ &= - \left[\sqrt{(1 - \dot{\tau}(t))} D^{-1} g(x(t - \tau(t))) - D W_1^T P x(t) \right]^T \\ &\quad \cdot \left[\sqrt{(1 - \dot{\tau}(t))} D^{-1} g(x(t - \tau(t))) - D W_1^T P x(t) \right] \\ &\quad + x^T(t) P W_1 D^2 W_1^T P x(t). \end{aligned} \quad (3.4)$$

Since the first term of the right-hand side of (3.4) is negative semidefinite, we obtain

$$\begin{aligned} &- (1 - \dot{\tau}(t)) g^T(x(t - \tau(t))) D^{-2} g(x(t - \tau(t))) \\ &\quad + 2x^T(t) P W_1 g(x(t - \tau(t))) \leq x^T(t) P W_1 D^2 W_1^T P x(t). \end{aligned} \quad (3.5)$$

From (A1), we obtain

$$g^T(x(t))D^{-2}g(x(t)) \leq x^T(t)MD^{-2}Mx(t), \quad (3.6)$$

where $M = \text{diag}\{l_1, l_2, \dots, l_n\}$.

Then by Lemma 2.6, we have

$$\begin{aligned} 2x^T(t)PWg(x(t)) &\leq x^T(t)Px(t) + [PWg(x(t))]^T P^{-1}PWg(x(t)) \\ &= x^T(t)Px(t) + g^T(x(t))W^T PWg(x(t)) \\ &\leq x^T(t)Px(t) + x^T(t)MW^T PWMx(t), \\ 2x^T(t)Pu(t) &\leq x^T(t)Px(t) + [Pu(t)]^T P^{-1}Pu(t) \\ &= x^T(t)Px(t) + u^T(t)Pu(t). \end{aligned} \quad (3.7)$$

Substituting (3.5), (3.6), and (3.7) into (3.3), we finally obtain

$$\begin{aligned} \dot{V}(x(t)) &\leq x^T(t)Gx(t) + u^T(t)Pu(t) \\ &\leq \lambda_{\min}(G)|x(t)|^2 + \lambda_{\max}(P)|u(t)|^2, \end{aligned} \quad (3.8)$$

where $G = -A^T P - PA + M(D^{-2} + W^T PW)M + PW_1 D^2 W_1^T P + P$.

Define $\alpha_3(r) = -\lambda_{\min}(G) \cdot r^2$, $\alpha_4(r) = \lambda_{\max}(P) \cdot r^2$, then we can obtain that

$$\dot{V}(x(t)) \leq -\alpha_3(|x(t)|) + \alpha_4(\|u\|_\infty). \quad (3.9)$$

Note that $G < 0$ is equivalent to (3.1) by Lemma 2.5. Then the defined V is an ISS Lyapunov-Krasovskii functional. It follows from Lemma 2.4 and Remark 2.3 that the delayed neural networks (2.9) are ISS. The proof is complete. $\square$

Remark 3.2. Theorem 3.1 reduces to asymptotically stability condition for dynamical neural networks with time-varying delays when $u(t) = 0$.

Remark 3.3. Recently, some results on ISS or IOSS were obtained in [10, 17–19, 26]. However, these results were restricted to nondelay or constant delay. In contrast to the results [10, 17–19, 26], we consider dynamical neural networks with time-varying delays and propose a set of delay-independent criteria for asymptotically convergent state estimation of these neural networks in this paper.

In the following, we give a delay-dependent sufficient criterion.

Theorem 3.4. Let (A1) and (A2) hold. The system (2.9) is ISS if there exist a symmetric positive definite matrix P and a positive definite matrix Q such that

$$-A^T P - PA + \tau Q = -\mu I, \quad \mu > 0, \quad \forall u \in L_\infty^m, \quad (3.10)$$

$$\left(\frac{2\|M\|\|W_1\|}{\sqrt{1-\dot{\tau}(t)}} + \|M\|^2\|W\|^2 + 2 \right) < \mu, \quad (3.11)$$

where $M = \text{diag}\{l_1, l_2, \dots, l_n\}$.

Proof. We consider the following functional:

$$V(x(t)) = x^T(t)Px(t) + \int_{-\tau(t)}^0 \int_{t+\zeta}^t x^T(\eta)Qx(\eta)d\eta d\zeta + \int_{t-\tau(t)}^t g^T(x(\zeta))Rg(x(\zeta))d\zeta, \quad (3.12)$$

where R is a positive definite matrix.

The derivative of (3.12) along the trajectories of the system is obtained as follows:

$$\begin{aligned} \dot{V}(x(t)) &= 2x^T(t)P[-Ax(t) + Wg(x(t)) + W_1g(x(t-\tau(t))) + u(t)] \\ &\quad + \tau(t)x^T(t)Qx(t) - (1-\dot{\tau}(t)) \int_{t-\tau(t)}^t x^T(\zeta)Qx(\zeta)d\zeta \\ &\quad + g^T(x(t))Rg(x(t)) - (1-\dot{\tau}(t))g^T(x(t-\tau(t)))Rg(x(t-\tau(t))) \\ &\leq x^T(t)(-A^T P - AP + \tau Q)x(t) + 2x^T(t)PWg(x(t)) + 2x^T(t)Pu(t) \\ &\quad + 2x^T(t)PW_1g(x(t-\tau(t))) - (1-\dot{\tau}(t)) \int_{t-\tau(t)}^t x^T(\zeta)Qx(\zeta)d\zeta \\ &\quad + g^T(x(t))Rg(x(t)) - (1-\dot{\tau}(t))g^T(x(t-\tau(t)))Rg(x(t-\tau(t))). \end{aligned} \quad (3.13)$$

From (3.10), which reduces to

$$\begin{aligned} \dot{V}(x(t)) &\leq -\mu x^T(t)x(t) + 2x^T(t)PWg(x(t)) + 2x^T(t)Pu(t) \\ &\quad + 2x^T(t)PW_1g(x(t-\tau(t))) - (1-\dot{\tau}(t)) \int_{t-\tau(t)}^t x^T(\zeta)Qx(\zeta)d\zeta \\ &\quad + g^T(x(t))Rg(x(t)) - (1-\dot{\tau}(t))g^T(x(t-\tau(t)))Rg(x(t-\tau(t))). \end{aligned} \quad (3.14)$$

From (A1), we obtain that

$$g^T(x(t))Rg(x(t)) \leq x^T(t)MRMx(t) \leq \|R\|\|M\|^2|x(t)|^2, \quad (3.15)$$

where $M = \text{diag}\{l_1, l_2, \dots, l_n\}$.

From Lemma 2.6, we have

$$\begin{aligned}
2x^T(t)PWg(x(t)) &\leq x^T(t)Px(t) + [PWg(x(t))]^T P^{-1}PWg(x(t)) \\
&= x^T(t)Px(t) + g^T(x(t))W^T PWg(x(t)) \\
&\leq x^T(t)Px(t) + x^T(t)MW^T PWMx(t) \\
&\leq \left(1 + \|M\|^2 \|W\|^2\right) \|P\| |x(t)|^2, \\
2x^T(t)PW_1g(x(t - \tau(t))) &\leq (1 - \dot{\tau}(t))g^T(x(t - \tau(t)))Rg(x(t - \tau(t))) \\
&\quad + \frac{1}{1 - \dot{\tau}(t)} x^T(t)PW_1R^{-1}W_1^T Px(t).
\end{aligned} \tag{3.16}$$

Then

$$\begin{aligned}
&2x^T(t)PW_1g(x(t - \tau(t))) - (1 - \dot{\tau}(t))g^T(x(t - \tau(t)))Rg(x(t - \tau(t))) \\
&\leq \frac{1}{1 - \dot{\tau}(t)} x^T(t)PW_1R^{-1}W_1^T Px(t) \leq \frac{1}{1 - \dot{\tau}(t)} \|R\|^{-1} \|W_1\|^2 \|P\|^2 |x(t)|^2.
\end{aligned} \tag{3.17}$$

For the third term of (3.14), we have

$$\begin{aligned}
2x^T(t)Pu(t) &\leq x^T(t)Px(t) + [Pu(t)]^T P^{-1}Pu(t) \\
&= x^T(t)Px(t) + u^T(t)Pu(t) \\
&\leq \|P\| |x(t)|^2 + \|P\| |u(t)|^2.
\end{aligned} \tag{3.18}$$

Substituting (3.15), (3.16), (3.17), and (3.18) into (3.14), we can obtain the following inequality:

$$\dot{V}(x(t)) \leq \lambda |x(t)|^2 + \|P\| |u(t)|^2, \tag{3.19}$$

where we denote that

$$\begin{aligned}
\lambda &= \left(-\mu + \|R\| \|M\|^2 + \|P\| \|M\|^2 \|W\|^2 + 2\|P\| + \frac{1}{1 - \dot{\tau}(t)} \|R\|^{-1} \|W_1\|^2 \|P\|^2 \right), \\
\|R\| &= \frac{\|W_1\| \|P\|}{\sqrt{1 - \dot{\tau}(t)} \|M\|}.
\end{aligned} \tag{3.20}$$

From (3.11), we easily obtain that $\lambda < 0$.

Define K_∞ -functions $\alpha_3(r) = -\lambda r^2$, $\alpha_4(r) = \|P\| \cdot r^2$. Then we can obtain that

$$\dot{V}(x(t)) \leq \alpha_3(|x(t)|) + \alpha_4(\|u\|_\infty). \tag{3.21}$$

From Lemma 2.4 and Remark 2.3, the system (2.9) is ISS. The proof is complete. $\square$

4. Illustrative Examples

In this section, we will give two examples to show the efficiency of the results derived in Section 3.

Example 4.1. Consider a 3-dimension dynamical neural network (2.9) with parameters defined as

$$A = \begin{pmatrix} 4 & 0 & 0 \\ 0 & 4 & 0 \\ 0 & 0 & 4 \end{pmatrix}, \quad W = W_1 = \begin{pmatrix} 1 & -0.1 & -0.2 \\ -0.1 & 1 & -0.3 \\ -0.2 & -0.3 & 1 \end{pmatrix}. \quad (4.1)$$

Letting $g_i(x_i) = 1/(1 + e^{-x_i})$ and the time-varying delay is chosen as $\tau(t) = 0.6|\sin t|$. They satisfy assumptions (A1) and (A2), respectively. Obviously, there exist $l_1 = l_2 = l_3 = 1$ and $\tau = 0.5, 0 < \dot{\tau}(t) < 0.6$ that satisfy the conditions. Then $M = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$.

By using MATLAB to solve the LMIs (3.1), we have

$$P = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \frac{1}{2} & 0 \\ 0 & 0 & \frac{1}{3} \end{pmatrix}, \quad D = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}. \quad (4.2)$$

From Theorem 3.1, we can see that delayed neural network (2.9) achieves ISS.

Example 4.2. Consider a 3-dimension dynamical neural network (2.9) with parameters followed as

$$A = \begin{pmatrix} 7.6 & 0 & 0 \\ 0 & 9.5 & 0 \\ 0 & 0 & 8.8 \end{pmatrix}, \quad W = W_1 = \begin{pmatrix} 0.40 & 0.12 & 0.32 \\ 0.45 & 0.02 & 0.10 \\ 0.12 & 0.04 & 0.42 \end{pmatrix}. \quad (4.3)$$

Letting $g_i(\theta) = (|\theta + 1| - |\theta - 1|)/2, \theta \in R$ and the time-varying delay is chosen as $\tau(t) = 1/(t + 2)$. We can check the assumptions (A1) and (A2) with $l_1 = l_2 = l_3 = 1$ and $0 \leq \tau(t) \leq 1, 0 \leq \dot{\tau}(t) \leq 0.5$ for any $t > 0$. Also we have $M = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$.

By solving (3.10) and (3.11), we get

$$P = \begin{pmatrix} 0.7 & 0.1 & 0.3 \\ 0.1 & 0.7 & 0.1 \\ 0.3 & 0.1 & 0.7 \end{pmatrix}, \quad Q = \begin{pmatrix} 2.82 & 0.855 & 2.46 \\ 0.855 & 4.15 & 0.915 \\ 2.46 & 0.915 & 3.16 \end{pmatrix}, \quad R = \begin{pmatrix} 0.927 & -0.03 & -0.02 \\ -0.03 & 9.28 & -0.08 \\ -0.01 & -0.02 & 9.25 \end{pmatrix}. \quad (4.4)$$

From Theorem 3.4, we can see that delayed neural network (2.9) obtains ISS.

However, the above results cannot be obtained by using criteria on ISS in existing publications (e.g., [10, 11, 17–19, 26]).

5. Conclusions

In this paper, dynamical neural networks with time-varying delays were considered. By using Lyapunov-Krasovskii functional method and linear matrix inequalities (LMIs) techniques, several theorems with regarding to judging the ISS property of DNNs with time-varying delays have been obtained. It is shown that the ISS can be determined by solving a set of LMIs, which can be checked by using some standard numerical packages in MATLAB. At last, two numerical examples were given to illustrate the theoretical results.

Appendix

Proof of Lemma 2.4. We divided into four parts to prove this lemma.

Claim 1. (i) The solution $x = 0$ of the system (2.9) is uniformly asymptotically stable if and only if there exists a function β of class KL and a positive number c independent of t_0 such that for for all $t \geq t_0$, for all $\|x_{t_0}\|_\tau \leq c$ it satisfies that

$$|x(t)| \leq \beta(\|x_{t_0}\|_\tau, t - t_0). \quad (\text{A.1})$$

Particularly, the system (2.9) is uniformly global asymptotically stable if and only if (A.1) admits for any $x_{t_0} \in C$.

The Claim is so trivial that we omit the proof here. $\square$

Claim 2. For each $(t, \phi) \in R^+ \times C$, if there exist a continuous functional $V(t, \phi) : R^+ \times C \rightarrow R^+$, functions α_1, α_2 of class K_∞ , and a continuous positive definite function W such that

$$\alpha_1(|\phi(0)|) \leq V(t, \phi) \leq \alpha_2(\|\phi\|_\tau), \quad (\text{A.2})$$

$$\dot{V}(t, \phi) \leq -W(|\phi(0)|), \quad (\text{A.3})$$

then the solution $x(t) = 0$ is globally uniformly asymptotically stable, and there exist a $\beta \in KL$ such that

$$|x(t)| \leq \beta(\|x_{t_0}\|_\tau, t - t_0), \quad \forall (t_0, x_{t_0}) \in R^+ \times C, t \geq t_0. \quad (\text{A.4})$$

Proof. From [27], the solution $x(t) = 0$ is globally uniformly asymptotically stable. Then by Claim 1, we obtain (A.4). The proof is complete. $\square$

Claim 3. Let (A.3) in Claim 2 replaced by

$$\dot{V}(t, \phi) \leq -W(|\phi(0)|), \quad \forall |\phi(0)| \geq \mu > 0. \quad (\text{A.5})$$

Then for any $x_{t_0} \in C$, there exist $\beta \in KL, T \triangleq T(x_{t_0}, \mu)$, such that

$$\begin{aligned} |x(t)| &\leq \beta(\|x_{t_0}\|_\tau, t - t_0), \quad \forall t \in [t_0, t_0 + T], \\ |x(t)| &\leq \alpha_1^{-1}(\alpha_2(\mu)), \quad \forall t \geq t_0 + T. \end{aligned} \quad (\text{A.6})$$

Proof. Let $B_\mu \triangleq \{x \in R^n \mid \|x_{t_0}\|_\tau \leq \mu\}$, $B_\mu^c \triangleq R^n - B_\mu$, $D_\mu \triangleq \{x \in R^n \mid \|x_{t_0}\|_\tau \leq \alpha^{-1}(\alpha_2(\mu))\}$ (no loss generality, we assume that $\alpha_1(\mu) \leq \alpha_2(\mu)$, then $\mu \leq \alpha_1^{-1}(\alpha_2(\mu))$). Then $B_\mu \subseteq D_\mu$. In the following, we divided $x_{t_0} \in C$ into two parts.

Case 1. $x_{t_0} \in B_\mu$.

We make the claim that $x(t)$ will be always remain in B_μ . Define $t_1 = \inf\{t \geq t_0 : |x(t)| = \mu\}$, if $|x(t)| > \mu$, $t > t_1$, then $\|x(t)\| \geq \mu$, $t \geq t_1$ and $\dot{V}(t, \phi) \leq -\alpha_3(|\phi(0)|) < 0$, and we have $\alpha_1(|x(t)|) \leq V(t, x_t) \leq V(t, x_{t_1}) \leq \alpha_2(\|x_{t_1}\|_\tau)$, $t \geq t_1$. Then $|x(t)| \leq \alpha_1^{-1}(\alpha_2(\|x_{t_1}\|_\tau)) = \alpha_1^{-1}(\alpha_2(\mu))$. If $|x(t)| < \mu$, $t > t_1$, let $t_2 = \inf\{t \geq t_1 : |x(t)| = \mu\}$, we will analyze them as the above. Then we obtain $|x(t)| \leq \alpha_1^{-1}(\alpha_2(\mu))$, $t \geq t_0$.

Case 2. $x_{t_0} \in B_\mu^c$, that is, $\|x_{t_0}\|_\tau > \mu$.

Let $t_0 + T(x_{t_0}, \mu) = \inf\{t \geq t_0 : |x(t)| = \mu\}$ and $T = T(x_{t_0}, \mu)$. We prove that $t_0 + T$ is limit. From $|x(t)| \geq \mu$, $t \in [t_0, t_0 + T]$, (A.2), (A.5), and Case 2, we have $|x(t)| \leq \beta(\|x_{t_0}\|_\tau, t - t_0)$, where $\beta \in KL$. Since $\beta(\|x_{t_0}\|_\tau, t - t_0)$ is strictly decreasing, and $\beta(\|x_{t_0}\|_\tau, \cdot) \rightarrow 0$ as $t \rightarrow \infty$, $t_0 + T$ is limit. Then from Case 1, $x(t)$ will be always remain in D_μ if arrive the boundary of B_μ . Then we obtain (A.6). The proof is complete. $\square$

Claim 4. Let (A.3) in Claim 2 replaced by

$$\dot{V}(t, \phi) \leq -W(\|\phi(0)\|), \quad \text{if } \|\phi(0)\| \geq \rho(\|u\|_\infty), \quad (\text{A.7})$$

where $\rho \in K$. Then the system is ISS.

Proof. From Claim 3, we have

$$|x(t)| \leq \beta(\|x_{t_0}\|_\tau, t - t_0) + \alpha_1^{-1}(\alpha_2(\rho(\|u\|_\infty))), \quad t \geq t_0. \quad (\text{A.8})$$

Since $x(t)$ only depends on the $u(s)$ defined on $[t_0, t]$, we obtain

$$|x(t)| \leq \beta(\|x_{t_0}\|_\tau, t - t_0) + \alpha_1^{-1}(\alpha_2(\rho(\|u_t\|_\infty))), \quad t \geq t_0. \quad (\text{A.9})$$

Then

$$|x(t)| \leq \beta(\|x_{t_0}\|_\tau, t - t_0) + \gamma(\|u_t\|_\infty), \quad t \geq t_0, \quad (\text{A.10})$$

where $\gamma \triangleq \alpha_1^{-1}(\alpha_2(\rho))$. This proves that the system is ISS. $\square$
