A four-functional fixed point theorem and a generalization of Leggett-Williams fixed point theorem are used, respectively, to investigate the existence of at least one positive solution and at least three positive solutions for third-order m -point boundary value problem on time scales with an increasing homeomorphism and homomorphism, which generalizes the usual p -Laplacian operator. In particular, the nonlinear term $f(t, u)$ is allowed to change sign. As an application, we also give some examples to demonstrate our results.

1. Introduction

The theory of time scales was introduced by Hilger in his Ph.D. thesis in 1990 [1]. Theoretically, this new theory not only unifies continuous and discrete equations, but has also exhibited much more complicated dynamics on time scales. Moreover, the study of dynamic equations on time scales has led to several important applications, for example, insect population models, biology, neural networks, heat transfer, and epidemic models (see [2, 3] and references therein). Some preliminary definitions and theorems on time scales also can be found in books [2, 3], which are excellent references for calculus on time scales.

Multipoint boundary value problem (BVP) arises in a variety of different areas of applied mathematics and physics [4]. The study of multipoint BVPs for linear second-order ordinary differential equations was initiated by Ilin and Moiseev [5], since then many authors studied more general nonlinear multipoint boundary value problems ([6, 7] and references therein). Recently, when φ_p is p -Laplacian operator, that is, $\varphi_p(u) = |u|^{p-2}u$ ($p > 1$) and the nonlinear term does not depend on the first-order derivative, the existence problems of positive solutions of boundary value problems have attracted much attention. One can notice

that the oddness of the p -Laplacian operator is key to the proof. However, in the operator ϕ is not necessary odd, so it improves and generalizes the p -Laplacian operator.

There are few works that investigate the existence of positive solutions by using four functionals fixed point theorem [8] or a generalization of Leggett-Williams fixed point theorem [9]. Avery et al. [8] present a four-functional fixed point theorem, which is a major generalization of the original Leggett-Williams fixed point theorem [10]. To our knowledge, this fixed point theorem so far has only been used by Sun et al. [11]. By using the four-functional fixed point theorem and five-functional fixed point theorem, they obtain the existence criteria of at least one positive solution and three positive solutions for the nonlocal BVP with p -Laplacian. Liu and Sun [12] discussed the existence of at least three and arbitrary odd number positive solutions for m -point boundary value problems on time scale. They used a generalization of Leggett-Williams fixed point theorem [9].

There have been extensive studies on BVP with sign-changing nonlinearity [13–17]. Most of these results are obtained by using the fixed point theorem on cone [18, 19]. To the best of our knowledge, positive solutions of third-order m -point BVP for an increasing homeomorphism and homomorphism with sign-changing nonlinearity on time scales by using four functionals fixed point theorem [8] or a generalization of Leggett-Williams fixed point theorem [9] have not been considered till now. Our aim in this paper is to fill the gap.

In this paper, motivated by above results, we consider the existence of at least one or three positive solutions of the following third-order m -point boundary value problem (BVP) on time scales

$$\begin{aligned} & \left(\phi \left(u^{\Delta \nabla}(t) \right) \right)^{\nabla} + a(t)f(t, u(t)) = 0, \quad t \in [0, T]_{\mathbb{T}}, \\ & u(0) = \sum_{i=1}^{m-2} b_i u(\xi_i), \quad u^{\Delta}(T) = 0, \quad \phi \left(u^{\Delta \nabla}(0) \right) = \sum_{i=1}^{m-2} c_i \phi \left(u^{\Delta \nabla}(\xi_i) \right), \end{aligned} \quad (1.1)$$

where $\phi : \mathbb{R} \rightarrow \mathbb{R}$ is an increasing homeomorphism and homomorphism with $\phi(0) = 0$. A projection $\phi : \mathbb{R} \rightarrow \mathbb{R}$ is called an increasing homeomorphism and homomorphism if the following conditions are satisfied.

- (i) If $x \leq y$, then $\phi(x) \leq \phi(y)$, for all $x, y \in \mathbb{R}$;
- (ii) ϕ is continuous bijection and its inverse mapping is also continuous;
- (iii) $\phi(xy) = \phi(x)\phi(y)$, for all $x, y \in \mathbb{R}$.

We will assume that the following conditions are satisfied throughout this paper:

- (H1) $b_i, c_i \in [0, +\infty)$, $0 < \xi_1 < \xi_2 < \cdots < \xi_{m-2} < \rho(T)$, $0 < \sum_{i=1}^{m-2} b_i < 1$, $0 < \sum_{i=1}^{m-2} c_i < 1$;
- (H2) $f : [0, T]_{\mathbb{T}} \times [0, +\infty) \rightarrow (-\infty, +\infty)$ is continuous, $a \in \mathcal{C}_{\text{id}}([0, T]_{\mathbb{T}}, [0, +\infty))$, and there exist $t_0 \in [0, T]_{\mathbb{T}}$ such that $a(t_0) > 0$;
- (H3) $\zeta = \min\{t \in \mathbb{T} : t > T/2\}$ exist.

By using a four-functional fixed point theorem [8], we establish the existence of at least one positive solution, and by using a generalization of Leggett-Williams fixed point theorem [9], we establish the existence of at least three positive solutions for the above boundary value problem. In particular, the nonlinear term $f(t, u(t))$ is allowed to change sign. The remainder of this paper is organized as follows. Section 2 is devoted to some preliminary lemmas. We give and prove our main results in Section 3. Finally, in Section 4, we give two examples to demonstrate our results.

2. Preliminary Lemmas

In this section, we present some definitions and lemmas, which will be needed in the proof of the main results.

Lemma 2.1 (see [13]). *If condition (H1) holds, then for $h \in C_{\text{ld}}[0, T]_{\mathbb{T}}$, the boundary value problem (BVP),*

$$\begin{aligned} u^{\Delta \nabla} + h(t) &= 0, \quad t \in [0, T]_{\mathbb{T}}, \\ u(0) &= \sum_{i=1}^{m-2} b_i u(\xi_i), \quad u^{\Delta}(T) = 0, \end{aligned} \quad (2.1)$$

has a unique solution

$$u(t) = \int_0^t (T-s)h(s)\nabla s + \frac{\sum_{i=1}^{m-2} b_i \int_0^{\xi_i} (T-s)h(s)\nabla s}{1 - \sum_{i=1}^{m-2} b_i}. \quad (2.2)$$

Lemma 2.2. *If condition (H1) holds, then for $h \in C_{\text{ld}}[0, T]_{\mathbb{T}}$, the boundary value problem (BVP),*

$$\begin{aligned} \left(\phi \left(u^{\Delta \nabla}(t) \right) \right)^{\nabla} + h(t) &= 0, \quad t \in [0, T]_{\mathbb{T}}, \\ u(0) &= \sum_{i=1}^{m-2} b_i u(\xi_i), \quad u^{\Delta}(T) = 0, \quad \phi \left(u^{\Delta \nabla}(0) \right) = \sum_{i=1}^{m-2} c_i \phi \left(u^{\Delta \nabla}(\xi_i) \right), \end{aligned} \quad (2.3)$$

has a unique solution

$$u(t) = \int_0^t (s-T)\phi^{-1} \left(- \int_0^s h(r)\nabla r + D \right) \nabla s + \frac{\sum_{i=1}^{m-2} b_i \int_0^{\xi_i} (s-T)\phi^{-1} \left(- \int_0^s h(r)\nabla r + D \right) \nabla s}{1 - \sum_{i=1}^{m-2} b_i}, \quad (2.4)$$

where $D = -(\sum_{i=1}^{m-2} c_i \int_0^{\xi_i} h(r)\nabla r) / (1 - \sum_{i=1}^{m-2} c_i)$.

Proof. Integrating both sides of equation in (2.3) on $[0, t]$, we have

$$\phi \left(u^{\Delta \nabla}(t) \right) = \phi \left(u^{\Delta \nabla}(0) \right) - \int_0^t h(r)\nabla r. \quad (2.5)$$

So,

$$\phi \left(u^{\Delta \nabla}(\xi_i) \right) = \phi \left(u^{\Delta \nabla}(0) \right) - \int_0^{\xi_i} h(r)\nabla r. \quad (2.6)$$

By boundary value condition $\phi(u^{\Delta \nabla}(0)) = \sum_{i=1}^{m-2} c_i \phi(u^{\Delta \nabla}(\xi_i))$, we have

$$\phi(u^{\Delta \nabla}(0)) = -\frac{\sum_{i=1}^{m-2} c_i \int_0^{\xi_i} h(r) \nabla r}{1 - \sum_{i=1}^{m-2} c_i}. \quad (2.7)$$

By (2.5) and (2.7), we know

$$u^{\Delta \nabla}(t) = \phi^{-1} \left(-\frac{\sum_{i=1}^{m-2} c_i \int_0^{\xi_i} h(r) \nabla r}{1 - \sum_{i=1}^{m-2} c_i} - \int_0^t h(r) \nabla r \right). \quad (2.8)$$

This together with Lemma 2.1 implies that

$$u(t) = \int_0^t (s-T) \phi^{-1} \left(-\int_0^s h(r) \nabla r + D \right) \nabla s + \frac{\sum_{i=1}^{m-2} b_i \int_0^{\xi_i} (s-T) \phi^{-1} \left(-\int_0^s h(r) \nabla r + D \right) \nabla s}{1 - \sum_{i=1}^{m-2} b_i}, \quad (2.9)$$

where $D = -(\sum_{i=1}^{m-2} c_i \int_0^{\xi_i} h(r) \nabla r) / (1 - \sum_{i=1}^{m-2} c_i)$. The proof is complete. $\square$

Lemma 2.3. *Let condition (H1) hold. If $h \in \mathcal{C}_{\text{ld}}[0, T]_{\mathbb{T}}$ and $h(t) \geq 0$, then the unique solution $u(t)$ of (2.3) satisfies*

- (i) $u(t) \geq 0$, $t \in [0, T]_{\mathbb{T}}$,
- (ii) $\inf_{t \in [0, T]_{\mathbb{T}}} u(t) \geq \sigma \|u\|$,

where $\sigma = \sum_{i=1}^{m-2} b_i \xi_i / (T - \sum_{i=1}^{m-2} b_i (T - \xi_i))$, $\|u\| = \sup_{t \in [0, T]_{\mathbb{T}}} |u(t)|$.

Proof. (i) Let $\psi_0(s) := \phi^{-1}(-\int_0^s h(r) \nabla r + D)$. Consider the following equation:

$$-\int_0^s h(r) \nabla r + D = -\int_0^s h(r) \nabla r - \frac{\sum_{i=1}^{m-2} c_i \int_0^{\xi_i} h(r) \nabla r}{1 - \sum_{i=1}^{m-2} c_i} \leq 0. \quad (2.10)$$

So, we have $\psi_0(s) \leq 0$. Hence $u(t) \geq 0$, $t \in [0, T]_{\mathbb{T}}$.

(ii) By $u^{\Delta \nabla}(t) = \phi^{-1}(-\int_0^t h(r) \nabla r + D) \leq 0$, we can know that the graph of $u(t)$ is concave down on $(0, T)_{\mathbb{T}}$ and $u^{\Delta}(t)$ is nonincreasing on $[0, T]_{\mathbb{T}}$. This together with the assumption that the boundary condition $u^{\Delta}(T) = 0$ implies that $u^{\Delta}(t) \geq 0$ for $t \in [0, T]_{\mathbb{T}}$. This implies that

$$\|u\| = u(T), \quad \min_{t \in [0, T]_{\mathbb{T}}} u(t) = u(0). \quad (2.11)$$

For all $i \in \{1, 2, \dots, m-2\}$, we have from the concavity of u that

$$\frac{u(\xi_i) - u(0)}{\xi_i} \geq \frac{u(T) - u(0)}{T}, \quad (2.12)$$

that is,

$$u(\xi_i) - u(0) + \frac{\xi_i}{T}u(0) \geq \frac{\xi_i}{T}u(T). \quad (2.13)$$

This together with the boundary condition $u(0) = \sum_{i=1}^{m-2} b_i u(\xi_i)$ implies that

$$\min_{t \in [0, T]_{\mathbb{T}}} u(t) \geq \frac{\sum_{i=1}^{m-2} b_i \xi_i}{T - \sum_{i=1}^{m-2} b_i (T - \xi_i)} u(T). \quad (2.14)$$

This completes the proof. $\square$

Let $E = C_{\text{id}}[0, T]_{\mathbb{T}}$ be equipped with the norm $\|u\| = \max_{t \in [0, T]_{\mathbb{T}}} |u(t)|$. Clearly, it follows that $(E, \|u\|)$ is a Banach space. For the convenience, let

$$\varphi(s) = \phi^{-1} \left(-\frac{\sum_{i=1}^{m-2} c_i \int_0^{\xi_i} a(r) \nabla r}{1 - \sum_{i=1}^{m-2} c_i} - \int_0^s a(r) \nabla r \right). \quad (2.15)$$

We define two cones by

$$\begin{aligned} P &= \{u : u \in E, u(t) \geq 0, t \in [0, T]_{\mathbb{T}}\}, \\ K &= \left\{ u : u \in E, u(t) \text{ is concave, nondecreasing, nonnegative on } [0, T]_{\mathbb{T}}, \right. \\ &\quad \left. \min_{t \in [0, T]_{\mathbb{T}}} u(t) \geq \sigma \|u\| \right\}, \end{aligned} \quad (2.16)$$

where σ is as in Lemma 2.3. Define the operators $F : P \rightarrow E$ and $S : K \rightarrow E$ by setting

$$\begin{aligned} (Fu)(t) &= \int_0^t (s - T) \phi^{-1} \left(-\int_0^s a(r) f(r, u(r)) \nabla r + A \right) \nabla s \\ &\quad + \frac{\sum_{i=1}^{m-2} b_i \int_0^{\xi_i} (s - T) \phi^{-1} \left(-\int_0^s a(r) f(r, u(r)) \nabla r + A \right) \nabla s}{1 - \sum_{i=1}^{m-2} b_i}, \end{aligned} \quad (2.17)$$

where $A = -(\sum_{i=1}^{m-2} c_i \int_0^{\xi_i} a(r) f(r, u(r)) \nabla r) / (1 - \sum_{i=1}^{m-2} c_i)$,

$$(Su)(t) = \int_0^t (s - T) \varphi(s) \nabla s + \frac{\sum_{i=1}^{m-2} b_i \int_0^{\xi_i} (s - T) \varphi(s) \nabla s}{1 - \sum_{i=1}^{m-2} b_i}, \quad (2.18)$$

where $\varphi(s) = \phi^{-1}(-\int_0^s a(r) f^+(r, u(r)) \nabla r + \tilde{A})$, $\tilde{A} = -(\sum_{i=1}^{m-2} c_i \int_0^{\xi_i} a(r) f^+(r, u(r)) \nabla r) / (1 - \sum_{i=1}^{m-2} c_i)$, and $f^+(t, u(t)) = \max\{f(t, u(t)), 0\}$. Obviously, u is a solution of the BVP (1.1) if and only if u is a fixed point of operator F .

Lemma 2.4. $S : K \rightarrow K$ is completely continuous.

Proof. It is easy to see that $SK \subset K$ by $f^+ \geq 0$ and Lemma 2.3. By Arzela-Ascoli theorem and Lebesgue dominated convergence theorem, we can easily prove that operator S is completely continuous. $\square$

3. Main Results

In this section, we prove the existence of at least one positive solution to the BVP (1.1) by applying a four-functional fixed point theorem [8]. Also, by using the generalization of Leggett-Williams fixed point theorem [9], we prove the existence of at least three positive solutions for the BVP (1.1).

Let α and Ψ be nonnegative continuous concave functionals on P , and let β and θ be nonnegative continuous convex functionals on P , then for positive numbers r, j, v , and R , we define the following sets:

$$\begin{aligned} Q(\alpha, \beta, r, R) &= \{x \in P : r \leq \alpha(x), \beta(x) \leq R\}, \\ U(\Psi, j) &= \{x \in Q(\alpha, \beta, r, R) : j \leq \Psi(x)\}, \\ V(\theta, v) &= \{x \in Q(\alpha, \beta, r, R) : \theta(x) \leq v\}. \end{aligned} \quad (3.1)$$

Theorem 3.1 (see [8]). *If P is a cone in a real Banach space E , α and Ψ are nonnegative continuous concave functionals on P , β , and θ are nonnegative continuous convex functionals on P and there exist positive numbers r, j, v , and R , such that*

$$A : Q(\alpha, \beta, r, R) \longrightarrow P \quad (3.2)$$

is a completely continuous operator, and $Q(\alpha, \beta, r, R)$ is a bounded set. If

- (i) $\{x \in U(\Psi, j) : \beta(x) < R\} \cap \{x \in V(\theta, v) : r < \alpha(x)\} \neq \emptyset$,
- (ii) $\alpha(Ax) \geq r$, for all $x \in Q(\alpha, \beta, r, R)$, with $\alpha(x) = r$ and $v < \theta(Ax)$,
- (iii) $\alpha(Ax) \geq r$, for all $x \in V(\theta, v)$, with $\alpha(x) = r$,
- (iv) $\beta(Ax) \leq R$, for all $x \in Q(\alpha, \beta, r, R)$, with $\beta(x) = R$ and $\Psi(Ax) < j$,
- (v) $\beta(Ax) \leq R$, for all $x \in U(\Psi, j)$, with $\beta(x) = R$,

then A has a fixed point x in $Q(\alpha, \beta, r, R)$.

Suppose $\tau, \eta \in \mathbb{T}$ with $0 < \tau < \eta < T$. For convenience, we take the notations

$$\begin{aligned} \overline{w} &= \frac{\sum_{i=1}^{m-2} b_i}{1 - \sum_{i=1}^{m-2} b_i}, \quad N_\eta = \int_0^\eta (s - T)\psi(s)\nabla s, \quad N_{m-2} = \int_0^{\xi_{m-2}} (s - T)\psi(s)\nabla s, \\ N_\tau &= \int_0^\tau (s - T)\psi(s)\nabla s, \quad N_T = \int_0^T (s - T)\psi(s)\nabla s, \\ N_0 &= \int_0^\tau (s - T)\phi^{-1}\left(-\int_0^s a(r)\nabla r\right)\nabla s. \end{aligned} \quad (3.3)$$

Theorem 3.2. Assume that (H1), (H2) hold if there exist constants r, j, v, R with $R > \max\{(N_T + N_{m-2}\bar{\omega})/N_\tau, T/\tau\}j$, $v \geq \max\{((N_\eta + N_{m-2}\bar{\omega})/N_\tau)j, (\eta/\tau)r\}$, $r < j$, and suppose that $f(t, u)$ satisfies the following conditions:

- (B1) $f(t, u) \leq \phi(R/(N_T + N_{m-2}\bar{\omega}))$ for all $(t, u) \in [0, T]_\mathbb{T} \times [0, R]$;
- (B2) $f(t, u) \geq \phi(r/N_0)$ for all $(t, u) \in [0, \tau]_\mathbb{T} \times [r, v]$;
- (B3) $f(t, u) \geq 0$ for all $(t, u) \in [0, T]_\mathbb{T} \times [\sigma r, R]$.

Then the BVP (1.1) has a fixed point $u \in P$ such that

$$\min_{t \in [\tau, \eta]_\mathbb{T}} u(t) \geq r, \quad \max_{t \in [0, T]_\mathbb{T}} u(t) \leq R. \quad (3.4)$$

Define maps

$$\alpha(u) = \Psi(u) = \min_{t \in [\tau, \eta]_\mathbb{T}} u(t), \quad \theta(u) = \max_{t \in [\tau, \eta]_\mathbb{T}} u(t), \quad \beta(u) = \max_{t \in [0, T]_\mathbb{T}} u(t). \quad (3.5)$$

Let $Q(\alpha, \beta, r, R)$, $U(\Psi, j)$, and $V(\theta, v)$ be defined by (3.1).

Proof. We first show that $Q(\alpha, \beta, r, R)$ is bounded and $S : Q(\alpha, \beta, r, R) \rightarrow K$ is completely continuous. For all $u \in Q(\alpha, \beta, r, R)$, we have $\|u\| = \max_{t \in [0, T]_\mathbb{T}} u(t) = \beta(u) \leq R$, which means that $Q(\alpha, \beta, r, R)$ is a bounded set. According to Lemma 2.4, it is clear that $S : Q(\alpha, \beta, r, R) \rightarrow K$ is completely continuous.

Let

$$u_0 = \frac{j}{N_\tau} \left(\int_0^t (s-T)\psi(s)\nabla s + \frac{\sum_{i=1}^{m-2} b_i \int_0^{\xi_i} (s-T)\psi(s)\nabla s}{1 - \sum_{i=1}^{m-2} b_i} \right). \quad (3.6)$$

Clearly, $u_0 \in K$. By direct calculation,

$$\begin{aligned} \Psi(u_0) &= u_0(\tau) = \frac{j}{N_\tau} \left(\int_0^\tau (s-T)\psi(s)\nabla s + \frac{\sum_{i=1}^{m-2} b_i \int_0^{\xi_i} (s-T)\psi(s)\nabla s}{1 - \sum_{i=1}^{m-2} b_i} \right) \\ &\geq \frac{j}{N_\tau} \int_0^\tau (s-T)\psi(s)\nabla s = j, \\ \beta(u_0) &= \frac{j}{N_\tau} \left(\int_0^T (s-T)\psi(s)\nabla s + \frac{\sum_{i=1}^{m-2} b_i \int_0^{\xi_i} (s-T)\psi(s)\nabla s}{1 - \sum_{i=1}^{m-2} b_i} \right) \\ &\leq \frac{j}{N_\tau} \left(\int_0^T (s-T)\psi(s)\nabla s + \frac{\sum_{i=1}^{m-2} b_i \int_0^{\xi_{m-2}} (s-T)\psi(s)\nabla s}{1 - \sum_{i=1}^{m-2} b_i} \right) \\ &= \frac{j}{N_\tau} (N_T + \bar{\omega}N_{m-2}) < R, \end{aligned}$$

$$\begin{aligned}
\theta(u_0) &= \frac{j}{N_\tau} \left(\int_0^\eta (s-T)\varphi(s)\nabla s + \frac{\sum_{i=1}^{m-2} b_i \int_0^{\xi_i} (s-T)\varphi(s)\nabla s}{1 - \sum_{i=1}^{m-2} b_i} \right) \\
&\leq \frac{j}{N_\tau} \left(\int_0^\eta (s-T)\varphi(s)\nabla s + \frac{\sum_{i=1}^{m-2} b_i \int_0^{\xi_{m-2}} (s-T)\varphi(s)\nabla s}{1 - \sum_{i=1}^{m-2} b_i} \right) \\
&= \frac{j}{N_\tau} (N_\eta + \bar{\omega} N_{m-2}) \leq v, \\
\alpha(u_0) &= \Psi(u_0) \geq j > r.
\end{aligned} \tag{3.7}$$

So, $u_0 \in \{u \in \mathcal{U}(\Psi, j) : \beta(u) < R\} \cap \{u \in V(\theta, v) : r < \alpha(u)\}$, which means that (i) in Theorem 3.1 is satisfied.

For all $u \in Q(\alpha, \beta, r, R)$, with $\alpha(u) = r$ and $v < \theta(Su)$, we have

$$\alpha(Su) = (Su)(\tau) \geq \frac{\tau}{\eta} (Su)(\eta) = \frac{\tau}{\eta} \theta(Su) > \frac{\tau}{\eta} v \geq r, \tag{3.8}$$

and for all $u \in Q(\alpha, \beta, r, R)$, with $\beta(u) = R$ and $\Psi(Su) < j$, we have

$$\beta(Su) = (Su)(T) \leq \frac{T}{\tau} (Su)(\tau) = \frac{T}{\tau} \Psi(Su) < \frac{T}{\tau} j < R. \tag{3.9}$$

Hence (ii) and (iv) in Theorem 3.1 are fulfilled.

Lastly, we consider Theorem 3.1 (iii) and (v). For all $V(\theta, v)$, with $\alpha(u) = r$,

$$\begin{aligned}
\alpha(Su) &= \int_0^\tau (s-T)\varphi(s)\nabla s + \frac{\sum_{i=1}^{m-2} b_i \int_0^{\xi_i} (s-T)\varphi(s)\nabla s}{1 - \sum_{i=1}^{m-2} b_i} \\
&\geq \int_0^\tau (s-T)\phi^{-1} \left(- \int_0^s a(r)f^+(r, u(r))\nabla r - \frac{\sum_{i=1}^{m-2} c_i \int_0^{\xi_i} a(r)f^+(r, u(r))\nabla r}{1 - \sum_{i=1}^{m-2} c_i} \right) \nabla s \\
&\geq \int_0^\tau (s-T)\phi^{-1} \left(- \int_0^s a(r)f^+(r, u(r))\nabla r \right) \nabla s \geq \frac{r}{N_0} \int_0^\tau (s-T)\phi^{-1} \left(- \int_0^s a(r)\nabla r \right) \nabla s = r,
\end{aligned} \tag{3.10}$$

and for all $u \in U(\Psi, j)$, with $\beta(u) = R$,

$$\begin{aligned} \beta(Su) &= \int_0^T (s-T)\varphi(s)\nabla s + \frac{\sum_{i=1}^{m-2} b_i \int_0^{\xi_i} (s-T)\varphi(s)\nabla s}{1 - \sum_{i=1}^{m-2} b_i} \\ &\leq \int_0^T (s-T)\varphi(s)\nabla s + \frac{\sum_{i=1}^{m-2} b_i \int_0^{\xi_{m-2}} (s-T)\varphi(s)\nabla s}{1 - \sum_{i=1}^{m-2} b_i} \\ &\leq \frac{R}{N_T + N_{m-2}\overline{w}} \left(\int_0^T (s-T)\varphi(s)\nabla s + \overline{w} \int_0^{\xi_{m-2}} (s-T)\varphi(s)\nabla s \right) = R. \end{aligned} \quad (3.11)$$

Thus, all conditions of Theorem 3.1 are satisfied. S has a fixed point u in $Q(\alpha, \beta, r, R)$. Clearly, $\sigma r \leq u(t) \leq R$, $t \in [0, T]_{\mathbb{T}}$. By condition (B3), we have $f(t, u(t)) \geq 0$, $t \in [0, T]_{\mathbb{T}}$, that is, $f^+(t, u(t)) = f(t, u(t))$. Hence, $Fu = Su$. This means that u is a fixed point of operator F . Therefore, the BVP (1.1) has at least one positive solution. $\square$

Suppose α and β are two nonnegative continuous convex functionals satisfying

$$\|x\| \leq L \max\{\alpha(x), \beta(x)\}, \quad x \in P, \quad (3.12)$$

where L is a positive constant, and

$$\Omega = \{x \in P : \alpha(x) < r, \beta(x) < l\} \neq \emptyset, \quad r > 0, l > 0. \quad (3.13)$$

Let $r > a > 0$, $l > 0$ be given, α, β nonnegative continuous convex functionals on P satisfying the relation (3.12) and (3.13), and γ a nonnegative continuous concave functional on P . We define the following convex sets:

$$\begin{aligned} P(\alpha, r; \beta, l) &= \{u \in P : \alpha(u) < r, \beta(u) < l\}, \\ \overline{P}(\alpha, r; \beta, l) &= \{u \in P : \alpha(u) \leq r, \beta(u) \leq l\}, \\ P(\alpha, r; \beta, l; \gamma, a) &= \{u \in P : \alpha(u) < r, \beta(u) < l, \gamma(u) > a\}, \\ \overline{P}(\alpha, r; \beta, l; \gamma, a) &= \{u \in P : \alpha(u) \leq r, \beta(u) \leq l, \gamma(u) \geq a\}. \end{aligned} \quad (3.14)$$

Theorem 3.3 (see [9]). *Let $\mathbb{B}$ be a Banach space, $P \subset \mathbb{B}$ a cone, and $r_2 \geq d > b > r_1 > 0$, $l_2 \geq l_1 > 0$. Assume that α and β are nonnegative continuous convex functionals satisfying (3.12) and (3.13), γ is a nonnegative continuous concave functional on P such that $\gamma(u) \leq \alpha(u)$ for all $u \in \overline{P}(\alpha, r_2; \beta, l_2)$, and $A : \overline{P}(\alpha, r_2; \beta, l_2) \rightarrow \overline{P}(\alpha, r_2; \beta, l_2)$ is a completely continuous operator. Suppose*

- (i) $\{u \in \overline{P}(\alpha, d; \beta, l_2; \gamma, b) : \gamma(u) > b\} \neq \emptyset$, $\gamma(Au) > b$ for $u \in \overline{P}(\alpha, d; \beta, l_2; \gamma, b)$;
- (ii) $\alpha(Au) < r_1$, $\beta(Au) < l_1$ for $u \in \overline{P}(\alpha, r_1; \beta, l_1)$;
- (iii) $\gamma(Au) > b$ for $u \in \overline{P}(\alpha, r_2; \beta, l_2; \gamma, b)$ with $\alpha(Au) > d$.

Then A has at least three fixed points $u_1, u_2, u_3 \in \overline{P}(\alpha, r_2; \beta, l_2)$ with

$$\begin{aligned} u_1 &\in P(\alpha, r_1; \beta, l_1), & u_2 &\in \left\{ \overline{P}(\alpha, r_2; \beta, l_2; \gamma, b) : \gamma(u) > b \right\}, \\ u_3 &\in \overline{P}(\alpha, r_2; \beta, l_2) \setminus \left(\overline{P}(\alpha, r_2; \beta, l_2; \gamma, b) \cup \overline{P}(\alpha, r_1; \beta, l_1) \right). \end{aligned} \quad (3.15)$$

It is easy to see that for $u \in K$, $u(t) \geq (t/T)\|u\|$, $t \in [0, T]_{\mathbb{T}}$. So we get

$$u(t) \geq \frac{\zeta}{T}\|u\| > \frac{1}{2}\|u\|, \quad t \in [\zeta, T]_{\mathbb{T}}, \quad (3.16)$$

where ζ is as in (H3). Let α , β , and γ be defined on the cone K by

$$\alpha(u) = \max_{t \in [0, T]_{\mathbb{T}}} u(t), \quad \beta(u) = \min_{t \in [0, T]_{\mathbb{T}}} u(t), \quad \gamma(u) = \min_{t \in [\zeta, T]_{\mathbb{T}}} u(t), \quad (3.17)$$

respectively. Then it is easy to see that $\|u\| = \max\{\alpha(u), \beta(u)\}$ and (3.12), (3.13) hold. Now, for convenience, let (3.3) and $M = \int_0^\zeta (s - T)\psi(\zeta)\nabla s$.

Theorem 3.4. Assume (H1)–(H3) hold, $f(t, 0)$ is not equivalent to 0 for $t \in [0, T]_{\mathbb{T}}$. If there are positive numbers $r_2 \geq 2b > b > r_1 > 0$, $l_2 \geq l_1 > 0$ with $b/M \leq \min\{r_2/(N_T + N_{m-2}\overline{w}), l_2/(N_{m-2}\overline{w})\}$, such that the following conditions are satisfied.

$$(C1) \quad 0 \leq f(t, u) \leq \min\{\phi(r_2/(N_T + N_{m-2}\overline{w})), \phi(l_2/(N_{m-2}\overline{w}))\} \text{ for } (t, u) \in [0, T]_{\mathbb{T}} \times [0, r_2],$$

$$(C2) \quad f(t, u) > \phi(b/M) \text{ for } (t, u) \in [\zeta, T]_{\mathbb{T}} \times [b, 2b],$$

$$(C3) \quad f(t, u) < \min\{\phi(r_1/(N_T + N_{m-2}\overline{w})), \phi(l_1/(N_{m-2}\overline{w}))\} \text{ for } (t, u) \in [0, T]_{\mathbb{T}} \times [0, r_1].$$

Then the BVP (1.1) has at least three positive solutions u_1, u_2, u_3 satisfying

$$\begin{aligned} \max_{t \in [0, T]_{\mathbb{T}}} u_1(t) &< r_1, & \min_{t \in [0, T]_{\mathbb{T}}} u_1(t) &< l_1, \\ b &< \min_{t \in [\zeta, T]_{\mathbb{T}}} u_2(t) \leq \max_{t \in [0, T]_{\mathbb{T}}} u_2(t) \leq r_2, & \min_{t \in [0, T]_{\mathbb{T}}} u_2(t) &\leq l_2, \\ \max_{t \in [0, T]_{\mathbb{T}}} u_3(t) &< 2b, & \text{with } \min_{t \in [\zeta, T]_{\mathbb{T}}} u_3(t) &< b, & \min_{t \in [0, T]_{\mathbb{T}}} u_3(t) &\leq l_2. \end{aligned} \quad (3.18)$$

Proof. By the definition of S , it suffices to show that the conditions of Theorem 3.3 hold with respect to the operator S . Firstly, we show that if the condition (C1) is satisfied, then

$$S : \overline{K}(\alpha, r_2; \beta, l_2) \longrightarrow \overline{K}(\alpha, r_2; \beta, l_2). \quad (3.19)$$

If $u \in \overline{K}(\alpha, r_2; \beta, l_2)$, then assumption (C1) implies

$$\begin{aligned}
 f(t, u) &\leq \min \left\{ \phi \left(\frac{r_2}{N_T + N_{m-2}\overline{w}} \right), \phi \left(\frac{l_2}{N_{m-2}\overline{w}} \right) \right\}, \quad t \in [0, T]_{\mathbb{T}}, \\
 \alpha(Su) &= \int_0^T (s-T)\varphi(s) \nabla s + \frac{\sum_{i=1}^{m-2} b_i \int_0^{\xi_i} (s-T)\varphi(s) \nabla s}{1 - \sum_{i=1}^{m-2} b_i} \\
 &\leq \int_0^T (s-T)\varphi(s) \nabla s + \frac{\sum_{i=1}^{m-2} b_i \int_0^{\xi_{m-2}} (s-T)\varphi(s) \nabla s}{1 - \sum_{i=1}^{m-2} b_i} \\
 &\leq \frac{r_2}{N_T + N_{m-2}\overline{w}} \int_0^T (s-T)\varphi(s) \nabla s + \overline{w} \int_0^{\xi_{m-2}} (s-T)\varphi(s) \nabla s = r_2, \\
 \beta(Su) &= \frac{\sum_{i=1}^{m-2} b_i \int_0^{\xi_i} (s-T)\varphi(s) \nabla s}{1 - \sum_{i=1}^{m-2} b_i} \\
 &\leq \frac{l_2}{N_{m-2}\overline{w}} \int_0^{\xi_{m-2}} (s-T)\varphi(s) \nabla s = l_2.
 \end{aligned} \tag{3.20}$$

Therefore, (3.19) holds. In the same way, if $u \in \overline{K}(\alpha, r_1; \beta, l_1)$, then condition (C3) implies

$$f(t, u) < \min \left\{ \phi \left(\frac{r_1}{N_T + N_{m-2}\overline{w}} \right), \phi \left(\frac{l_1}{N_{m-2}\overline{w}} \right) \right\}, \quad t \in [0, T]_{\mathbb{T}}. \tag{3.21}$$

As the argument above, we have $S : \overline{K}(\alpha, r_1; \beta, l_1) \rightarrow K(\alpha, r_1; \beta, l_1)$. Thus, condition (ii) of Theorem 3.3 holds. To check the condition (i) of Theorem 3.3, we choose

$$\overline{u}_0(t) = \frac{2bt}{T}, \quad t \in [0, T]_{\mathbb{T}}. \tag{3.22}$$

It is easy to see that $\overline{u}_0(t) \in \overline{K}(\alpha, 2b; \beta, l_2; \gamma, b)$, $\gamma(\overline{u}_0) > b$. Therefore, for $u \in \overline{K}(\alpha, 2b; \beta, l_2; \gamma, b)$, there are $b \leq u(t) \leq 2b$, $t \in [\zeta, T]_{\mathbb{T}}$. Hence, condition (C2) implies $f(t, u) > \phi(b/M)$, $t \in [\zeta, T]_{\mathbb{T}}$. So, by the definition of γ ,

$$\begin{aligned}
 \gamma(Su) &= \int_0^{\zeta} (s-T)\varphi(s) \nabla s + \frac{\sum_{i=1}^{m-2} b_i \int_0^{\xi_i} (s-T)\varphi(s) \nabla s}{1 - \sum_{i=1}^{m-2} b_i} \geq \int_0^{\zeta} (s-T)\varphi(s) \nabla s \\
 &= \int_0^{\zeta} (s-T)\phi^{-1} \left(- \int_0^s a(r)f^+(r, u(r)) \nabla r - \frac{\sum_{i=1}^{m-2} c_i \int_0^{\xi_i} a(r)f^+(r, u(r)) \nabla r}{1 - \sum_{i=1}^{m-2} c_i} \right) \nabla s
 \end{aligned}$$

$$\begin{aligned}
&\geq \int_0^\zeta (s-T)\phi^{-1}\left(-\int_0^\zeta a(r)f^+(r,u(r))\nabla r - \frac{\sum_{i=1}^{m-2} c_i \int_0^{\xi_i} a(r)f^+(r,u(r))\nabla r}{1 - \sum_{i=1}^{m-2} c_i}\right)\nabla s \\
&> \frac{b}{M} \int_0^\zeta (s-T)\phi^{-1}\left(-\int_0^\zeta a(r)\nabla r - \frac{\sum_{i=1}^{m-2} c_i \int_0^{\xi_i} a(r)\nabla r}{1 - \sum_{i=1}^{m-2} c_i}\right)\nabla s = b.
\end{aligned} \tag{3.23}$$

Hence, condition (i) of Theorem 3.3 holds. We finally prove that (iii) in Theorem 3.3 holds. In fact, for $u \in \overline{K}(\alpha, 2b; \beta, l_2; \gamma, b)$ with $\alpha(Su) > 2b$, we have $\gamma(Su) > b$. Thus from Theorem 3.3, the BVP (1.1) has at least three fixed points $u_1, u_2, u_3 \in \overline{K}(\alpha, r_2; \beta, l_2)$. Clearly, $0 \leq u_1(t) \leq r_1$, $\sigma b < u_2(t) \leq r_2$, $0 \leq u_3(t) \leq 2b$, $t \in [0, T]_{\mathbb{T}}$. By condition (C1), we have $f(t, u(t)) \geq 0$, $t \in [0, T]_{\mathbb{T}}$, that is, $f^+(t, u(t)) = f(t, u(t))$. Hence, $Fu = Su$. This means that u_1, u_2, u_3 are fixed points of operator F . Therefore, the BVP (1.1) has at least three positive solutions. $\square$

4. Example

Example 4.1. Let $\mathbb{T} = [0, 1/2] \cup \{0.6\} \cup [0.7, 1]$. If we choose $T = 1$, $a(t) = 1$, $b_1 = 1/3$, $c_1 = 1/2$, $\xi_1 = 1/4$ in the boundary value problem (1.1), then we have the following BVP on time scale $\mathbb{T}$:

$$\begin{aligned}
&\left(\phi\left(u^{\Delta\nabla}(t)\right)\right)^\nabla + f(t, u(t)) = 0, \quad t \in [0, 1]_{\mathbb{T}}, \\
&u(0) = \frac{1}{3}u\left(\frac{1}{4}\right), \quad u^\Delta(1) = 0, \quad \phi\left(u^{\Delta\nabla}(0)\right) = \frac{1}{2}\phi\left(u^{\Delta\nabla}\left(\frac{1}{4}\right)\right),
\end{aligned} \tag{4.1}$$

where

$$\begin{aligned}
\phi(u) &= \begin{cases} u, & u \leq 0, \\ u^2, & u > 0, \end{cases} \\
f(t, u) &= \begin{cases} 95(u - 0.0001) + 0.0007, & [0, 1]_{\mathbb{T}} \times [0, 0.0001], \\ 0.0007, & [0, 1]_{\mathbb{T}} \times [0.0001, \infty). \end{cases}
\end{aligned} \tag{4.2}$$

Set $\tau = 1/3$, $\eta = 0.6$, by calculation,

$$\begin{aligned}
\overline{w} &= \frac{1}{2}, \quad N_T = \frac{1721}{6000}, \quad N_{m-2} = \frac{31}{384}, \quad N_\tau = \frac{73}{648}, \quad N_0 = \frac{7}{162}, \\
N_\eta &= \frac{2533}{12000}, \quad \sigma = \frac{1}{9},
\end{aligned} \tag{4.3}$$

and let $r = 0.001$, $j = r + 10^{-4}$, $R = 0.012$, and $v = 0.0035$ with $0.012 > 0.0033$, $0.0035 \geq 0.002455$. Clearly, we can verify that the conditions in Theorem 3.2 are fulfilled. Thus, by Theorem 3.2, the BVP (4.1) has a fixed point u such that

$$\min_{t \in [1/3, 0.6]_{\mathbb{T}}} u(t) \geq 0.001, \quad \max_{t \in [0, 1]_{\mathbb{T}}} u(t) \leq 0.012. \quad (4.4)$$

Example 4.2. Let $\mathbb{T} = [0, 1] \cup \{1.2\} \cup \{1.5\} \cup [1.8, 2]$. If we choose $T = 2$, $a(t) = 1$, $b_1 = 1/4$, $c_1 = 1/3$, $\xi_1 = 2/3$ in the boundary value problem (1.1), then we have the following BVP on time scale $\mathbb{T}$:

$$\begin{aligned} & \left(\phi \left(u^{\Delta \nabla}(t) \right) \right)^{\nabla} + f(t, u(t)) = 0, \quad t \in [0, 2]_{\mathbb{T}}, \\ & u(0) = \frac{1}{4} u \left(\frac{2}{3} \right), \quad u^{\Delta}(2) = 0, \quad \phi \left(u^{\Delta \nabla}(0) \right) = \frac{1}{3} \phi \left(u^{\Delta \nabla} \left(\frac{2}{3} \right) \right), \end{aligned} \quad (4.5)$$

where

$$\begin{aligned} \phi(u) &= \begin{cases} u, & u \leq 0, \\ u^2, & u > 0, \end{cases} \\ f(t, u) &= \begin{cases} \frac{1}{80}t + \frac{1}{10}u^3, & t \in [0, 2]_{\mathbb{T}}, u \in [0, 4], \\ \frac{1}{80}t + \frac{8}{5}u, & t \in [0, 2]_{\mathbb{T}}, u \in (4, 200], \\ \frac{1}{80}t + (520 - u), & t \in [0, 2]_{\mathbb{T}}, u \in (200, \infty). \end{cases} \end{aligned} \quad (4.6)$$

Obviously the hypotheses (H1), (H2) hold and $f(t, 0)$ is not equivalent to 0 on $[0, 2]_{\mathbb{T}}$. By simple calculations, we have

$$\zeta = 1.2, \quad \overline{w} = \frac{1}{3}, \quad N_T = 1.859, \quad N_{m-2} = 0.716, \quad M = 2.5398. \quad (4.7)$$

If we choose $r_2 = 200$, $b = 2$, $r_1 = 1/2$, and $l_2 = 80$, $l_1 = 20$, then $f(t, u)$ satisfies

- (1) $0 \leq f(t, u) \leq 320.025 \leq \min\{\phi(r_2/(N_T + N_{m-2}\overline{w})), \phi(l_2/(N_{m-2}\overline{w}))\} = 9090$ for $(t, u) \in [0, 2]_{\mathbb{T}} \times [0, 200]$;
- (2) $f(t, u) \geq 0.815 > \phi(b/M) = 0.62$ for $(t, u) \in [1.2, 2]_{\mathbb{T}} \times [2, 4]$,
- (3) $f(t, u) \leq 0.0375 < \min\{\phi(r_1/(N_T + N_{m-2}\overline{w})), \phi(l_1/(N_{m-2}\overline{w}))\} = 0.0568$.

So, all conditions of Theorem 3.4 hold. Thus by Theorem 3.4, the BVP (4.5) has at least three positive solutions u_1, u_2, u_3 such that

$$\begin{aligned} \max_{t \in [0,2]_{\mathbb{T}}} u_1(t) &< \frac{1}{2}, & \min_{t \in [0,2]_{\mathbb{T}}} u_1(t) &< 20, \\ 2 &< \min_{t \in [1.2,2]_{\mathbb{T}}} u_2(t) \leq \max_{t \in [0,2]_{\mathbb{T}}} u_2(t) \leq 200, & \min_{t \in [0,2]_{\mathbb{T}}} u_2(t) &\leq 80, \\ \max_{t \in [0,2]_{\mathbb{T}}} u_3(t) &< 4, & \text{with } \min_{t \in [1.2,2]_{\mathbb{T}}} u_3(t) &< 2, & \min_{t \in [0,2]_{\mathbb{T}}} u_3(t) &\leq 80. \end{aligned} \quad (4.8)$$
