We provide some new type of mappings associated with pseudocontractions by introducing some actual examples in smooth and strictly convex Banach spaces. Moreover, we also find the significant inequality related to the mappings mentioned in the paper and the mappings defined from generalized mixed equilibrium problems on Banach spaces. We propose an iterative shrinking projection method for finding a common solution of generalized mixed equilibrium problems and fixed point problems of closed and ϕ -quasi-strict pseudo-contractions. Our results hold in reflexive, strictly convex, and smooth Banach spaces with the property (K) . The results of this paper improve and extend the corresponding results of Zhou and Gao (2010) and many others.

1. Introduction

It is well known that, in an infinite-dimensional Hilbert space, the normal Mann's iterative algorithm [1] has only weak convergence, in general, even for nonexpansive mappings [2, 3]. Consequently, in order to obtain strong convergence, Nakajo and Takahashi [4] modified the normal Mann's iteration algorithm, later well known as a hybrid projection iteration method. Since then, the hybrid method has undergone rapid developments. For the details, the readers are referred to papers [5–9] and the references therein.

Let E be a smooth Banach space, and let E^* be the dual of E . The function $\phi : E \times E \rightarrow \mathbb{R}$ is defined by

$$\phi(y, x) = \|y\|^2 - 2\langle y, Jx \rangle + \|x\|^2 \quad (1.1)$$

for all $x, y \in E$, which was studied by Alber [10], Kamimura and Takahashi [11], and Reich [12], where J is the normalized duality mapping from E to 2^{E^*} defined by

$$J(x) = \{f \in E^* : \langle x, f \rangle = \|x\|^2 = \|f\|^2\}, \quad (1.2)$$

where $\langle \cdot, \cdot \rangle$ denotes the duality pairing. It is well known that if E is smooth, then J is single valued and if E is strictly convex, then J is injective (one to one). Let C be a closed convex subset of E , and let T be a mapping from C into itself. We denote by $F(T)$ the set of fixed points of T . A point p in C is said to be an asymptotic fixed point of T [12] if C contains a sequence $\{x_n\}$, which converges weakly to p such that the strong $\lim_{n \rightarrow \infty} (x_n - Tx_n) = 0$. The set of asymptotic fixed points of T will be denoted by $\hat{F}(T)$. A mapping T from C into itself is called nonexpansive if $\|Tx - Ty\| \leq \|x - y\|$ for all $x, y \in C$ and relatively nonexpansive [13–16] if $\hat{F}(T) = F(T)$ and $\phi(p, Tx) \leq \phi(p, x)$ for all $x \in C$ and $p \in F(T)$. The asymptotic behavior of relatively nonexpansive mapping was studied in [13–16].

In 2005, Matsushita and Takahashi [16] proposed the hybrid iteration method with generalized projection for relatively nonexpansive mapping T in the framework of uniformly smooth and uniformly convex Banach spaces E as follows:

$$\begin{aligned} x_0 &\in C \text{ chosen arbitrarily,} \\ y_n &= J^{-1}(\alpha_n Jx_n + (1 - \alpha_n)JT x_n), \\ C_n &= \{z \in C : \phi(z, y_n) \leq \phi(z, x_n)\}, \\ Q_n &= \{z \in C : \langle x_n - z, Jx_0 - Jx_n \rangle \geq 0\}, \\ x_{n+1} &= \Pi_{C_n \cap Q_n}(x_0), \end{aligned} \quad (1.3)$$

where J is the duality mapping on E and $\Pi_C(\cdot)$ is the generalized projection from E onto a nonempty closed convex subset C . Based on the guidelines of Matsushita and Takahashi [16], Plubtieng and Ungchittrakool [17, 18] studied and developed (1.3) to the case of two relatively nonexpansive mappings and finite family of relatively nonexpansive mappings, respectively.

On the other hand, for a real Banach space E and the dual E^* , let C be a nonempty closed convex subset of E . Let $\Theta : C \times C \rightarrow \mathbb{R}$ a bifunction, $\varphi : C \rightarrow \mathbb{R}$ a real-valued function, and $A : C \rightarrow E^*$ be a nonlinear mapping. The generalized mixed equilibrium problem is to find $x \in C$ such that

$$\Theta(x, y) + \langle Ax, y - x \rangle + \varphi(y) - \varphi(x) \geq 0, \quad \forall y \in C. \quad (1.4)$$

The solution set of (1.4) is denoted by $\text{GMEP}(\Theta, A, \varphi)$, that is,

$$\text{GMEP}(\Theta, A, \varphi) = \{x \in C : \Theta(x, y) + \langle Ax, y - x \rangle + \varphi(y) - \varphi(x) \geq 0, \forall y \in C\}. \quad (1.5)$$

If $A = 0$, the problem (1.4) reduces to the mixed equilibrium problem for Θ , denoted by $\text{MEP}(\Theta, \varphi)$, which is to find $x \in C$ such that

$$\Theta(x, y) + \varphi(y) - \varphi(x) \geq 0, \quad \forall y \in C. \quad (1.6)$$

If $\Theta = 0$, the problem (1.4) reduces to the mixed variational inequality of Browder type, denoted by $\text{VI}(C, A, \varphi)$, which is to find $x \in C$ such that

$$\langle Ax, y - x \rangle + \varphi(y) - \varphi(x) \geq 0, \quad \forall y \in C. \quad (1.7)$$

If $A = 0$ and $\varphi = 0$, the problem (1.4) reduces to the equilibrium problem for Θ (for short, EP), denoted by $\text{EP}(\Theta)$, which is to find $x \in C$ such that

$$\Theta(x, y) \geq 0, \quad \forall y \in C. \quad (1.8)$$

If $\Theta = 0$ and $A = 0$, the problem (1.4) reduces to the minimization problem for φ , denoted by $\text{Argmin}(\varphi)$, which is to find $x \in C$ such that

$$\varphi(x) \leq \varphi(y), \quad \forall y \in C. \quad (1.9)$$

The above formulation (1.7) was shown in [19] to cover monotone inclusion problems, saddle point problems, variational inequality problems, minimization problems, optimization problems, vector equilibrium problems, and Nash equilibria in noncooperative games. In addition, there are several other problems, for example, the complementarity problem, fixed point problem and optimization problem, which can also be written in the form of (1.8). However, (1.4) is very general, it covers the problems mentioned above as special cases.

In 2007, S. Takahashi and W. Takahashi [20] and Tada and Takahashi [21, 22] proved weak and strong convergence theorems for finding a common element of the set of solution of an equilibrium problem (1.8) and the set of fixed points of a nonexpansive mapping in a Hilbert space. Takahashi et al. [9] studied a strong convergence theorem by the hybrid method for a family of nonexpansive mappings in Hilbert spaces as follows: $x_0 \in H$, $C_1 = C$ and $x_1 = P_{C_1} x_0$, and let

$$\begin{aligned} y_n &= \alpha_n x_n + (1 - \alpha_n) T_n x_n, \\ C_{n+1} &= \{z \in C_n : \|y_n - z\| \leq \|x_n - z\|\}, \\ x_{n+1} &= P_{C_{n+1}} x_0, \quad n \in \mathbb{N}, \end{aligned} \quad (1.10)$$

where $0 \leq \alpha_n \leq a < 1$ for all $n \in \mathbb{N}$ and $\{T_n\}$ is a sequence of nonexpansive mappings of C into itself such that $\bigcap_{n=1}^{\infty} F(T_n) \neq \emptyset$. They proved that if $\{T_n\}$ satisfies some appropriate conditions, then $\{x_n\}$ converges strongly to $P_{\bigcap_{n=1}^{\infty} F(T_n)} x_0$.

Motivated by Takahashi et al. [9], Takahashi and Zembayashi [23] (see also [24]) introduced and proved a hybrid projection algorithm for solving equilibrium problems and fixed point problems of a relatively nonexpansive mapping S in the framework of uniformly smooth and uniformly convex Banach space as follows:

$$\begin{aligned}
 x_0 &= x, & C_0 &= C, \\
 y_n &= J^{-1}(\alpha_n Jx_n + (1 - \alpha_n)JSx_n), \\
 u_n &\in C \text{ such that } \Theta(u_n, y) + \frac{1}{r_n} \langle y - u_n, Ju_n - Jy_n \rangle \geq 0, \quad \forall y \in C, \\
 C_{n+1} &= \{z \in C_n : \phi(z, u_n) \leq \phi(z, x_n)\}, \\
 x_{n+1} &= \Pi_{C_{n+1}} x,
 \end{aligned} \tag{1.11}$$

where $\Pi_{C_{n+1}}(\cdot)$ is the generalized projection from E onto C_{n+1} . Under some appropriate assumptions on Θ , $\{\alpha_n\}$, and $\{r_n\}$, they proved that the sequence $\{x_n\}$ converges strongly to $\Pi_{F(S) \cap \text{EP}(\Theta)}(x_0)$.

In 2010, Zhou and Gao [25] introduced the definition of a quasi-strict pseudocontraction related to the function ϕ and proved a hybrid projection algorithm for finding a fixed point of a closed and quasi-strict pseudocontraction in more general framework than uniformly smooth and uniformly convex Banach spaces as follows:

$$\begin{aligned}
 x_0 &\in E, \text{ chosen arbitrarily,} \\
 C_1 &= C, \\
 x_1 &= \Pi_{C_1}(x_0), \\
 u_n &\in C \text{ such that} \\
 C_{n+1} &= \left\{ z \in C_n : \phi(x_n, Tx_n) \leq \frac{2}{1-k} \langle x_n - z, Jx_n - JT x_n \rangle \right\}, \\
 x_{n+1} &= \Pi_{C_{n+1}}(x_0),
 \end{aligned} \tag{1.12}$$

where $\Pi_{C_{n+1}}$ is the generalized projection from E onto C_{n+1} . They proved that the sequence $\{x_n\}$ converges strongly to $\Pi_{F(T)}(x_0)$.

Motivated and inspired by the above research work, in this paper, we provide some new type of mappings associated with pseudocontractions by introducing some actual examples in smooth and strictly convex Banach spaces. Furthermore, by employing the inequality that appeared in Lemma 2.10 together with (1.12) and some facts of Zhou and Gao [25], we create an iterative shrinking projection method for finding a common solution of generalized mixed equilibrium problems and fixed point problems of closed and ϕ -quasi-strict pseudocontractions in the framework of reflexive, strictly convex, and smooth Banach spaces with the property (K) . The results of this research improve and extend the corresponding results of Zhou and Gao [25] and many others.

2. Preliminaries

In this paper, we denote by E and E^* a real Banach space and the dual space of E , respectively. Let C be a nonempty closed convex subset of E . We denote by J the normalized duality mapping from E to 2^{E^*} defined by (1.1). Let $S(E) := \{x \in E : \|x\| = 1\}$ be the unit sphere of E . Then, a Banach space E is said to be *strictly convex* $\|(x + y)/2\| < 1$ for all $x, y \in S(E)$ and $x \neq y$. It is also said to be *uniformly convex* if $\lim_{n \rightarrow \infty} \|x_n - y_n\| = 0$ for any two sequences $\{x_n\}$ and $\{y_n\}$ in $S(E)$ such that $\lim_{n \rightarrow \infty} \|(x_n + y_n)/2\| = 1$. The Banach space E is said to be *smooth* provided

$$\lim_{t \rightarrow 0} \frac{\|x + ty\| - \|x\|}{t} \quad (2.1)$$

exists for each $x, y \in S(E)$. In this case, the norm of E is said to be *Gâteaux differentiable*. The norm of E is said to be *Fréchet differentiable* if for each $x \in S(E)$, the limit (2.1) is attained uniformly for $y \in S(E)$. The norm of E is said to be *uniformly Fréchet differentiable* (and E is said to be *uniformly smooth*) if the limit (2.1) is attained uniformly for $x, y \in S(E)$.

A Banach space E is said to have the *property (K)* (or *Kadec-Klee property*) if for any sequence $\{x_n\} \subset E$ such that $x_n \rightarrow x$ weakly and $\|x_n\| \rightarrow \|x\|$, then $\|x_n - x\| \rightarrow 0$. For more information concerning property (K) the reader is referred to [26] and references cited there.

A mapping $T : C \rightarrow C$ is said to be *closed* if for any sequence $\{x_n\} \subset C$ with $x_n \rightarrow x$ and $Tx_n \rightarrow y$, $x = y$.

We also know the following properties (see [27–29] for details):

- (i) if E is smooth ($\Leftrightarrow E^*$ is strictly convex), then J is single-valued,
- (ii) if E is strictly convex ($\Leftrightarrow E^*$ is smooth), then J is one-to-one (i.e., $J(x) \cap J(y) = \emptyset$ for all $x \neq y$),
- (iii) if E is reflexive ($\Leftrightarrow E^*$ is reflexive), then J is surjective,
- (iv) if E^* is smooth and reflexive, then $J^{-1} : E^* \rightarrow 2^E$ is single-valued and demicontinuous (i.e., if $\{x_n^*\} \subset E^*$ such that $x_n^* \rightarrow x^*$, then $J^{-1}(x_n^*) \rightarrow J^{-1}(x^*)$),
- (v) E is uniformly smooth if and only if E^* is uniformly convex,
- (vi) if E is uniformly convex, then
  - (a) it is strictly convex,
  - (b) it is reflexive,
  - (c) it satisfies the property (K),
- (vii) if E is a Hilbert space, then J is the identity operator.

It is also very well known that if C is a nonempty closed convex subset of a Hilbert space H and $P_C : H \rightarrow C$ is the metric projection of H onto C , then P_C is nonexpansive. This fact actually characterizes Hilbert spaces, and, consequently, it is not available in more general Banach spaces. In this connection, Alber [10] recently introduced a generalized projection operator Π_C in a Banach space E that is an analogue of the metric projection in Hilbert spaces.

Let C be a nonempty closed convex subset of a smooth, strictly convex, and reflexive Banach space E , for any $x \in E$. The *generalized projection* $\Pi_C : E \rightarrow C$ is a map that assigns to

an arbitrary point $x \in E$ the minimum point of the functional $\phi(x, y)$, that is, $\Pi_C x = \bar{x}$, where $\bar{x}$ is the solution to the minimization problem

$$\phi(\bar{x}, x) = \min_{y \in C} \phi(y, x). \quad (2.2)$$

Existence and uniqueness of the operator Π_C follow from the properties of the functional $\phi(x, y)$ and strict monotonicity of the mapping J (see, e.g., [10, 11, 27, 29, 30]). In Hilbert spaces, $\phi(y, x) = \|y - x\|^2$ and Π_C coincides with the metric projection P_C .

It is obvious from the definition of function ϕ that

$$(\|y\| - \|x\|)^2 \leq \phi(y, x) \leq (\|y\| + \|x\|)^2, \quad \forall x, y \in E, \quad (2.3)$$

$$\phi(x, y) = \phi(x, z) + \phi(z, y) + 2\langle x - z, Jz - Jy \rangle, \quad \forall x, y, z \in E. \quad (2.4)$$

Remark 2.1. If E is a reflexive strictly convex and smooth Banach space, then, for $x, y \in E$, $\phi(x, y) = 0$ if and only if $x = y$. It is sufficient to show that if $\phi(x, y) = 0$, then $x = y$. From (2.3), we have $\|x\| = \|y\|$. This implies $\langle x, Jy \rangle = \|x\|^2 = \|Jy\|^2$. From the definitions of J , we have $Jx = Jy$. That is, $x = y$; one may consult [27, 29] for the details.

T is said to be a ϕ -quasi-strict pseudocontraction [25, page 230] if there exists a constant $k \in [0, 1)$ and $F(T) \neq \emptyset$ such that $\phi(p, Tx) \leq \phi(p, x) + k\phi(x, Tx)$ for all $x \in C$ and $p \in F(T)$. In particular, T is said to be ϕ -quasi-nonexpansive if $k = 0$ and T is said to be ϕ -quasi-pseudocontractive if $k = 1$.

Let C be a nonempty closed convex subset of a real Banach space E with the dual E^* . A mapping $A : D(A) \subset E \rightarrow E^*$ is said to be *monotone* if, for each $x, y \in D(A)$, the following inequality holds:

$$\langle x - y, Ax - Ay \rangle \geq 0. \quad (2.5)$$

A is said to be *r -inverse strongly monotone* if there exists a positive real number r such that

$$\langle x - y, Ax - Ay \rangle \geq r \|Ax - Ay\|_{E^*}^2, \quad \forall x, y \in D(A). \quad (2.6)$$

A is said to be *r -quasi inverse strongly monotone* if $A^{-1}(0) = \{z \in D(A) : Az = 0\} \neq \emptyset$ and there exists a positive real number r such that for each $u \in A^{-1}(0)$, the following inequality holds:

$$\langle x - u, Ax \rangle \geq r \|Ax\|_{E^*}^2, \quad \forall x \in D(A). \quad (2.7)$$

Without loss of generality we can assume that the constant $r \in (0, 1/2]$ since if A is $\hat{r}$ -quasi inverse strongly monotone (or $\hat{r}$ -inverse strongly monotone), then we can find $r \in (0, 1/2]$ such that $\hat{r} \geq r$ and then $\hat{r} \|Ax\|_{E^*}^2 \geq r \|Ax\|_{E^*}^2$ (or $\hat{r} \|Ax - Ay\|_{E^*}^2 \geq r \|Ax - Ay\|_{E^*}^2$) for all $\hat{r} > 0$ (i.e., A is r -quasi inverse strongly monotone).

The following is the example of ϕ -quasi-strict pseudocontractions in the framework of a smooth and strictly convex Banach space E .

Example 2.2. Let E be a smooth and strictly convex Banach space E with dual E^* and J a normalized duality mapping. Let $\alpha \in [0, 1]$, and define the mapping $A_\alpha : E \rightarrow E$ by

$$A_\alpha(x) = \alpha x, \quad \forall x \in E. \quad (2.8)$$

It follows that the mapping $JA_\alpha : E \rightarrow E^*$ with the set of zero points is given as

$$\begin{aligned} (JA_\alpha)^{-1}(0) &= \{z \in E : 0 = JA_\alpha(z) = J(\alpha z) = \alpha Jz\} \\ &= \begin{cases} \{0\}, & \text{if } 0 < \alpha \leq 1, \\ E, & \text{if } \alpha = 0. \end{cases} \end{aligned} \quad (2.9)$$

Thus for each $u \in (JA_\alpha)^{-1}(0)$ and $r \in (0, 1/2]$ if $0 < \alpha \leq 1$, we obtain

$$\begin{aligned} \langle x - u, JA_\alpha x \rangle &= \langle x - 0, JA_\alpha x \rangle = \langle x, J(\alpha x) \rangle = \langle x, \alpha J(x) \rangle = \alpha \|x\|^2 \\ &\geq \alpha^2 \|x\|^2 = \langle \alpha x, J(\alpha x) \rangle = \langle A_\alpha x, J(A_\alpha x) \rangle = \|A_\alpha x\|^2 \\ &= \|JA_\alpha x\|_{E^*}^2 \\ &\geq r \|JA_\alpha x\|_{E^*}^2, \quad \forall x \in E. \end{aligned} \quad (2.10)$$

On the other hand, if $\alpha = 0$, we have $\langle x - u, JA_\alpha x \rangle = 0 = r \|0\|_{E^*}^2 = r \|JA_\alpha x\|_{E^*}^2$, for all $x \in E$. Therefore, JA_α is r -quasi inverse strongly monotone. So, we can define the following set:

$$Q = \left\{ J\tilde{A} : E \rightarrow E^* \mid \langle x - u, J\tilde{A}x \rangle \geq r \|J\tilde{A}x\|_{E^*}^2, \quad \forall x \in E, \quad u \in (J\tilde{A})^{-1}(0) \right\}, \quad (2.11)$$

where $\tilde{A} : E \rightarrow E$ and $r \in (0, 1/2]$ (note that $JA_\alpha \in Q \neq \emptyset$). In the same way, let $\hat{A} : E \rightarrow E$, and define

$$\mathcal{L} = \left\{ J\hat{A} \in Q \mid J(x - \hat{A}x) = Jx - J\hat{A}x, \quad \langle x, J\hat{A}x \rangle = \langle \hat{A}x, Jx \rangle, \quad \forall x \in E \right\}. \quad (2.12)$$

We claim that $JA_\alpha \in \mathcal{L}$. Note that $JA_\alpha \in Q$, and let us consider

$$\begin{aligned} J(x - A_\alpha x) &= J(x - \alpha x) = (1 - \alpha)Jx = Jx - \alpha Jx = Jx - J(\alpha x) \\ &= Jx - JA_\alpha x. \end{aligned} \quad (2.13)$$

Furthermore, it is also found that

$$\langle x, JA_\alpha x \rangle = \langle x, J(\alpha x) \rangle = \langle \alpha x, Jx \rangle = \langle A_\alpha x, Jx \rangle. \quad (2.14)$$

This means that $JA_\alpha \in \mathcal{L} \neq \emptyset$. So, we have the claim.

Now, we pick arbitrarily $J\hat{A} \in \mathcal{L}$ and claim that $(I - \hat{A}) : E \rightarrow E$ is a ϕ -quasi-strict pseudocontraction (i.e., $\exists k \in [0, 1)$ s.t. $\phi(q, (I - \hat{A})x) \leq \phi(q, x) + k\phi(x, (I - \hat{A})x)$ for all $x \in E$ and $q \in F(I - \hat{A})$).

Since $J\hat{A} \in \mathcal{L}$, we have

$$\begin{aligned}
\|\hat{A}x\|^2 &= \langle \hat{A}x, J\hat{A}x \rangle = \langle x - (I - \hat{A})x, Jx - (Jx - J\hat{A}x) \rangle \\
&= \langle x - (I - \hat{A})x, Jx \rangle - \langle x - (I - \hat{A})x, J(I - \hat{A})x \rangle \\
&= \|x\|^2 - \langle (I - \hat{A})x, Jx \rangle - \langle x, J(I - \hat{A})x \rangle + \|(I - \hat{A})x\|^2 \\
&= \left(\|x\|^2 - 2\langle x, J(I - \hat{A})x \rangle + \|(I - \hat{A})x\|^2 \right) + \langle x, J(I - \hat{A})x \rangle - \langle (I - \hat{A})x, Jx \rangle \\
&= \phi(x, (I - \hat{A})x) + \langle x, Jx \rangle - \langle x, J\hat{A}x \rangle - \langle x, Jx \rangle + \langle \hat{A}x, Jx \rangle \\
&= \phi(x, (I - \hat{A})x).
\end{aligned} \tag{2.15}$$

Note that $\mathcal{L} \subset \mathcal{Q}$, and thus $(J\hat{A})^{-1}(0) \neq \emptyset$. It is not difficult to check that $(J\hat{A})^{-1}(0) = F(I - \hat{A})$. Therefore, for each $q \in F(I - \hat{A})$, we have

$$\begin{aligned}
\phi(q, (I - \hat{A})x) &= \|q\|^2 - 2\langle q, J(I - \hat{A})x \rangle + \|(I - \hat{A})x\|^2 \\
&= \|q\|^2 - 2\langle q, Jx - J\hat{A}x \rangle + \|(I - \hat{A})x\|^2 \\
&= \left(\|q\|^2 - 2\langle q, Jx \rangle + \|x\|^2 \right) - \|x\|^2 + 2\langle q, J\hat{A}x \rangle + \|(I - \hat{A})x\|^2 \\
&= \phi(q, x) - \|x\|^2 - 2\langle x - q, J\hat{A}x \rangle + 2\langle x, J\hat{A}x \rangle + \|(I - \hat{A})x\|^2 \\
&\leq \phi(q, x) - \|x\|^2 - 2r\|J\hat{A}x\|^2 + 2\langle x, Jx \rangle - 2\langle x, Jx - J\hat{A}x \rangle + \|(I - \hat{A})x\|^2 \\
&= \phi(q, x) - 2r\|\hat{A}x\|^2 + \left(\|x\|^2 - 2\langle x, J(I - \hat{A})x \rangle + \|(I - \hat{A})x\|^2 \right) \\
&= \phi(q, x) - 2r\phi(x, (I - \hat{A})x) + \phi(x, (I - \hat{A})x) \\
&= \phi(q, x) + (1 - 2r)\phi(x, (I - \hat{A})x) \\
&= \phi(q, x) + k\phi(x, (I - \hat{A})x),
\end{aligned} \tag{2.16}$$

where $k := (1 - 2r)$. So, we obtain the desired result.

Next, we claim that the mapping $(I - A_\alpha)$ as mentioned previously is closed. Let $\{x_n\} \subset E$ such that $x_n \rightarrow x$; then we have

$$\begin{aligned} (I - A_\alpha)x_n &= x_n - A_\alpha x_n = x_n - \alpha x_n = (1 - \alpha)x_n \\ &\longrightarrow (1 - \alpha)x \quad \text{as } n \longrightarrow \infty. \end{aligned} \quad (2.17)$$

Moreover, $(I - A_\alpha)x = x - A_\alpha x = x - \alpha x = (1 - \alpha)x$. This shows that $(I - A_\alpha)$ is a closed mapping.

Remark 2.3. A relatively nonexpansive mapping is a ϕ -quasi-strict pseudocontraction, but the converse may be not true.

Example 2.4. Let E be a reflexive, strictly convex, and smooth Banach space. Let $A \subset E \times E^*$ be a maximal monotone mapping such that $A^{-1}(0)$ is nonempty. Then, $J_r = (J + rA)^{-1}J$ is a closed and ϕ -quasi-strict pseudocontraction from E onto $D(A)$ with constant $k = 0$ and $F(J_r) = A^{-1}(0)$.

Example 2.5. Let Π_C be the generalized projection from a smooth, strictly convex, and reflexive Banach space E onto a nonempty closed convex subset C of E . Then, Π_C is a closed and ϕ -quasi-strict pseudocontraction from E onto C with constant $k = 0$ and $F(\Pi_C) = C$.

For solving the equilibrium problem for a bifunction $\Theta : C \times C \rightarrow \mathbb{R}$, let us assume that Θ satisfies the following conditions:

$$(A1) \quad \Theta(x, x) = 0 \text{ for all } x \in C,$$

$$(A2) \quad \Theta \text{ is monotone, that is, } \Theta(x, y) + \Theta(y, x) \leq 0 \text{ for all } x, y \in C,$$

$$(A3) \quad \text{for each } x, y, z \in C,$$

$$\lim_{t \downarrow 0} \Theta(tz + (1 - t)x, y) \leq \Theta(x, y), \quad (2.18)$$

$$(A4) \quad \text{for each } x \in C, y \mapsto \Theta(x, y) \text{ is convex and lower semicontinuous.}$$

Lemma 2.6 (Blum and Oettli [19]). *Let C be a nonempty closed convex subset of a smooth, strictly convex, and reflexive Banach space E , and let Θ be a bifunction of $C \times C$ into $\mathbb{R}$ satisfying (A1)–(A4). Let $r > 0$ and $x \in E$. Then, there exists $z \in C$ such that*

$$\Theta(z, y) + \frac{1}{r} \langle y - z, Jz - Jx \rangle \geq 0, \quad \forall y \in C. \quad (2.19)$$

Lemma 2.7 (Takahashi and Zembayashi [24]). *Let C be a closed convex subset of a uniformly smooth, strictly convex, and reflexive Banach space E , and let Θ be a bifunction from $C \times C$ to $\mathbb{R}$ satisfying (A1)–(A4). For $r > 0$ and $x \in E$, define a mapping $T_r : E \rightarrow C$ as follows:*

$$T_r x = \left\{ z \in C : \Theta(z, y) + \frac{1}{r} \langle y - z, Jz - Jx \rangle \geq 0, \forall y \in C \right\} \quad (2.20)$$

for all $x \in C$. Then, the following hold:

- (i) T_r is single valued,
- (ii) T_r is firmly nonexpansive-type mapping, that is, for any $x, y \in H$,

$$\langle T_r x - T_r y, JT_r x - JT_r y \rangle \leq \langle T_r x - T_r y, Jx - Jy \rangle, \quad (2.21)$$

- (iii) $F(T_r) = \text{EP}(\Theta)$,
- (iv) $\text{EP}(\Theta)$ is closed and convex

Lemma 2.8 (Takahashi and Zembayashi [24]). *Let C be a closed convex subset of a smooth, strictly convex and reflexive Banach space E , let Θ be a bifunction from $C \times C$ to $\mathbb{R}$ satisfying (A1)–(A4), and let $r > 0$. Then, for $x \in E$ and $q \in F(T_r)$,*

$$\phi(p, T_r x) + \phi(T_r x, x) \leq \phi(p, x). \quad (2.22)$$

Lemma 2.9 (Zhang [31]). *Let C be a closed convex subset of a smooth, strictly convex, and reflexive Banach space E . Let $A : C \rightarrow E^*$ be a continuous and monotone mapping, $\varphi : C \rightarrow \mathbb{R}$ a lower semi-continuous and convex function, and Θ a bifunction from $C \times C$ to $\mathbb{R}$ satisfying (A1)–(A4). For $r > 0$ and $x \in E$, there exists $u \in C$ such that*

$$\Theta(u, y) + \langle Au, y - u \rangle + \varphi(y) - \varphi(u) + \frac{1}{r} \langle y - u, Ju - Jx \rangle \geq 0, \quad \forall y \in C. \quad (2.23)$$

Define a mapping $K_r : C \rightarrow C$ as follows:

$$K_r(x) = \left\{ u \in C : \Theta(u, y) + \langle Au, y - u \rangle + \varphi(y) - \varphi(u) + \frac{1}{r} \langle y - u, Ju - Jx \rangle \geq 0, \forall y \in C \right\} \quad (2.24)$$

for all $x \in C$. Then, the following conclusions hold:

- (1) K_r is single valued,
- (2) K_r is firmly nonexpansive type, that is, for all $x, y \in E$,

$$\langle K_r x - K_r y, JK_r x - JK_r y \rangle \leq \langle K_r x - K_r y, Jx - Jy \rangle, \quad (2.25)$$

- (3) $F(K_r) = \text{GMEP}(\Theta, A, \varphi)$,
- (4) $\text{GMEP}(\Theta, A, \varphi)$ is closed and convex,
- (5) $\phi(p, K_r x) + \phi(K_r x, x) \leq \phi(p, x) \quad \forall p \in F(K_r), x \in E$.

The following lemmas are crucial for the proofs of the main results in this paper.

Lemma 2.10. *Let E be a reflexive, strictly convex, and smooth Banach space. Assume that C is a nonempty closed convex subset of E . Let $T : C \rightarrow C$ be a ϕ -quasi-strict pseudocontraction, and let $K_r : C \rightarrow C$ be as in Lemma 2.9 such that $\Omega := F(T) \cap \text{GMEP}(\Theta, A, \varphi) \neq \emptyset$. Then*

$$\phi(x, K_rTx) + \phi(K_rTx, Tx) \leq \frac{2}{1-k} \langle x - p, Jx - JTx \rangle + 2 \langle x - p, JTx - JK_rTx \rangle \quad (2.26)$$

for all $x \in C$ and $p \in \Omega$.

Proof. Let $x \in C$ and $p \in \Omega$. By the ϕ -quasi-strict pseudocontractility of T and (2.4) we have

$$\begin{aligned} \phi(p, Tx) &\leq \phi(p, x) + k\phi(x, Tx) \\ &\Leftrightarrow \phi(p, x) + \phi(x, Tx) + 2 \langle p - x, Jx - JTx \rangle \leq \phi(p, x) + k\phi(x, Tx) \\ &\Leftrightarrow \phi(x, Tx) \leq \frac{2}{1-k} \langle x - p, Jx - JTx \rangle. \end{aligned} \quad (2.27)$$

It follows from (2.4), Lemma 2.9 (5), and (2.27) that

$$\begin{aligned} &\phi(p, x) + \phi(x, K_rTx) + 2 \langle p - x, Jx - JK_rTx \rangle \\ &= \phi(p, K_rTx) \\ &\leq \phi(p, Tx) - \phi(K_rTx, Tx) \\ &\leq \phi(p, x) + k\phi(x, Tx) - \phi(K_rTx, Tx) \\ &\leq \phi(p, x) + 2 \frac{k}{1-k} \langle x - p, Jx - JTx \rangle - \phi(K_rTx, Tx), \end{aligned} \quad (2.28)$$

and then

$$\begin{aligned} &\phi(x, K_rTx) + \phi(K_rTx, Tx) \\ &\leq 2 \frac{k}{1-k} \langle x - p, Jx - JTx \rangle + 2 \langle x - p, Jx - JK_rTx \rangle \\ &= 2 \frac{k}{1-k} \langle x - p, Jx - JTx \rangle + 2 \langle x - p, Jx - JTx \rangle + 2 \langle x - p, JTx - JK_rTx \rangle \\ &= \left(2 \frac{k}{1-k} + 2 \right) \langle x - p, Jx - JTx \rangle + 2 \langle x - p, JTx - JK_rTx \rangle \\ &= \frac{2}{1-k} \langle x - p, Jx - JTx \rangle + 2 \langle x - p, JTx - JK_rTx \rangle. \end{aligned} \quad (2.29)$$

□

Lemma 2.11 (Alber and Reich [10]). *Let C be a nonempty closed convex subset of a smooth Banach space E , $x_0 \in C$, and $x \in E$. Then, $x_0 = \Pi_C x$ if and only if*

$$\langle x_0 - y, Jx - Jx_0 \rangle \geq 0, \quad \forall y \in C. \quad (2.30)$$

Lemma 2.12 (Alber [30]). *Let E be a reflexive, strictly convex, and smooth Banach space, let C be a nonempty closed convex subset of E , and let $x \in E$. Then*

$$\phi(y, \Pi_C x) + \phi(\Pi_C x, x) \leq \phi(y, x), \quad \forall y \in C. \quad (2.31)$$

3. Main Result

Theorem 3.1. *Let E be a reflexive, strictly convex, and smooth Banach space such that E and E^* have the property (K). Assume that C is a nonempty closed convex subset of E . Let $T : C \rightarrow C$ be a closed and ϕ -quasi-strict pseudocontraction, Θ a bifunction from $C \times C$ to $\mathbb{R}$ satisfying (A1)–(A4), $\varphi : C \rightarrow \mathbb{R}$ a lower semi-continuous and convex function, and $A : C \rightarrow E^*$ a continuous and monotone mapping such that $\Omega := F(T) \cap \text{GMEP}(\Theta, A, \varphi) \neq \emptyset$. Define a sequence $\{x_n\}$ in C by the following algorithm:*

$x_0 \in E$, chosen arbitrarily,

$C_1 = C$,

$x_1 = \Pi_{C_1}(x_0)$,

$u_n \in C$ such that

$$\Theta(u_n, y) + \langle Au_n, y - u_n \rangle + \varphi(y) - \varphi(u_n) + \frac{1}{r_n} \langle y - u_n, Ju_n - JTx_n \rangle \geq 0, \quad \forall y \in C, \quad (3.1)$$

$$C_{n+1} = \left\{ z \in C_n : \phi(x_n, u_n) + \phi(u_n, Tx_n) \leq \frac{2}{1-k} \langle x_n - z, Jx_n - JTx_n \rangle + 2 \langle x_n - z, JTx_n - Ju_n \rangle \right\},$$

$x_{n+1} = \Pi_{C_{n+1}}(x_0)$,

where $k \in [0, 1)$ and $r_n > 0$ for all $n \in \mathbb{N}$ with $\liminf_{n \rightarrow \infty} r_n > 0$. Then, $\{x_n\}$ converges strongly to $\Pi_\Omega(x_0)$.

Proof. The proof is divided into seven steps.

Step 1. Show that Ω is closed and convex.

From step 1 of Zhou and Gao [25], $F(T)$ is closed and convex and by Lemma 2.9(4) $\text{GMEP}(\Theta, A, \varphi)$ is closed and convex. So, $\Omega := F(T) \cap \text{GMEP}(\Theta, A, \varphi)$ is closed and convex.

Step 2. Show that C_n is closed and convex for all $n \geq 1$.

For $n = 1$, $C_1 = C$ is closed and convex. Assume that C_k is closed and convex for some $k \in \mathbb{N}$. For $z \in C_{k+1}$, one obtains that

$$\phi(x_k, u_k) + \phi(u_k, Tx_k) \leq \frac{2}{1-k} \langle x_k - z, Jx_k - JTx_k \rangle + 2 \langle x_k - z, JTx_k - Ju_k \rangle. \quad (3.2)$$

It is not hard to see that the continuity and linearity of $\langle \cdot, Jx_k - JTx_k \rangle$ and $\langle \cdot, JTx_k - Ju_k \rangle$ allow C_{k+1} to be closed and convex. Then, for all $n \geq 1$, C_n is closed and convex.

Step 3. Show that $\Omega \subset C_n$ for all $n \geq 1$.

It is obvious that $\Omega := F(T) \cap \text{GMEP}(\Theta, A, \varphi) \subset C = C_1$. Suppose that $\Omega \subset C_k$ for some $k \in \mathbb{N}$. For any $p \in \Omega$, we have $p \in C_k$. Notice that $x_k = \Pi_{C_k}(x_0)$, and then by Lemma 2.9 we obtain $u_k = K_{r_k}Tx_k$. So, it follows from Lemma 2.10 that

$$\phi(x_k, u_k) + \phi(u_k, Tx_k) \leq \frac{2}{1-k} \langle x_k - p, Jx_k - JTx_k \rangle + 2 \langle x_k - p, JTx_k - Ju_k \rangle. \quad (3.3)$$

This means that $p \in C_{k+1}$. By mathematical induction, $\Omega \subset C_n$ for all $n \geq 1$. Therefore, $\Omega \subset \bigcap_{n=1}^{\infty} C_n =: D \neq \emptyset$.

Step 4. Show that $\lim_{n \rightarrow \infty} \phi(x_n, x_0)$ exists.

By $x_n = \Pi_{C_n}x_0$ and Lemma 2.12, we have

$$\phi(x_n, x_0) = \phi(\Pi_{C_n}x_0, x_0) \leq \phi(w, x_0) - \phi(w, x_n) \leq \phi(w, x_0), \quad (3.4)$$

for each $w \in \Omega \subset C_n$ and for all $n \geq 1$. Therefore, the sequence $\{\phi(x_n, x_0)\}$ is bounded.

On the other hand, noticing that $x_n = \Pi_{C_n}x_0$ and $x_{n+1} = \Pi_{C_{n+1}}x_0 \in C_{n+1} \subset C_n$, $\phi(x_n, x_0) = \min_{z \in C_n} \phi(z, x_0) \leq \phi(x_{n+1}, x_0)$ for all $n \geq 1$. Therefore, $\phi(x_n, x_0)$ is nondecreasing. It follows that the limit of $\phi(x_n, x_0)$ exists.

Step 5. Show that $x_n \rightarrow q$ as $n \rightarrow \infty$, where $q = \Pi_Dx_0$.

Since $x_{n+1} = \Pi_{C_{n+1}}x_0 \in C_{n+1} \subset C_n$ for any positive integer n and by Lemma 2.12, we have

$$\phi(x_{n+1}, x_n) = \phi(x_{n+1}, \Pi_{C_n}x_0) \leq \phi(x_{n+1}, x_0) - \phi(\Pi_{C_n}x_0, x_0) = \phi(x_{n+1}, x_0) - \phi(x_n, x_0). \quad (3.5)$$

Letting $n \rightarrow \infty$ in (3.5), one has $\phi(x_{n+1}, x_n) \rightarrow 0$ as $n \rightarrow \infty$. Without loss of generality, we can assume that $x_n \rightarrow q$ weakly as $n \rightarrow \infty$ (passing to a subsequence if necessary). It is easy to show that $q \in C_n$ for all $n \geq 1$. Hence $q \in \bigcap_{n=1}^{\infty} C_n = D$. Noticing that $\phi(x_n, x_0) \leq \phi(x_{n+1}, x_0) \leq \phi(q, x_0)$, we have

$$(q, x_0) \leq \liminf_{n \rightarrow \infty} \phi(x_n, x_0) \leq \limsup_{n \rightarrow \infty} \phi(x_n, x_0) \leq \phi(q, x_0), \quad (3.6)$$

which implies that $\phi(x_n, x_0) \rightarrow \phi(q, x_0)$ as $n \rightarrow \infty$. Hence $\|x_n\| \rightarrow \|q\|$. By the property (K) of E , we have $x_n \rightarrow q$. From Lemma 2.11, we have

$$\langle x_n - y, Jx_0 - Jx_n \rangle \geq 0, \quad \forall y \in D. \quad (3.7)$$

Hence

$$\langle q - y, Jx_0 - Jq \rangle \geq 0, \quad \forall y \in D, \quad (3.8)$$

which implies that $q = \Pi_Dx_0$.

Step 6. Show that $q \in \Omega$.

We prove first that $\{Tx_n\}$ and $\{u_n\} = \{K_{r_n}Tx_n\}$ are bounded. Indeed, taking $p \in \Omega = F(T) \cap \text{GMEP}(\Theta, A, \varphi) \subset C_{n+1}$, we have

$$\begin{aligned}
 & \|p\|^2 - 2\|p\|\|Tx_n\| + \|Tx_n\|^2 \\
 &= (\|p\| - \|Tx_n\|)^2 \leq \phi(p, Tx_n) \\
 &\leq \phi(p, x_n) + k\phi(x_n, Tx_n) \\
 &\leq \phi(p, x_n) + \frac{2k}{1-k} \langle x_n - p, Jx_n - JTx_n \rangle \\
 &\leq \phi(p, x_n) + \frac{2k}{1-k} \|x_n - p\| \|x_n\| + \frac{2k}{1-k} \|x_n - p\| \|Tx_n\|.
 \end{aligned} \tag{3.9}$$

Then

$$\begin{aligned}
 \|Tx_n\|^2 &\leq \left(\phi(p, x_n) - \|p\|^2 + \frac{2k}{1-k} \|x_n - p\| \|x_n\| \right) + \left(\frac{2k}{1-k} \|x_n - p\| + 2\|p\| \right) \|Tx_n\| \\
 &\leq M + K\|Tx_n\| = M + \frac{1}{2}(2K\|Tx_n\|) \\
 &\leq M + \frac{1}{2}(K^2 + \|Tx_n\|^2) = M + \frac{1}{2}K^2 + \frac{1}{2}\|Tx_n\|^2,
 \end{aligned} \tag{3.10}$$

where $M := \sup\{\phi(p, x_n) - \|p\|^2 + (2k/(1-k))\|x_n - p\|\|x_n\| : n \in \mathbb{N}\}$ and $K := \sup\{(2k/(1-k))\|x_n - p\| + 2\|p\| : n \in \mathbb{N}\}$. Thus

$$\|Tx_n\|^2 \leq 2M + K^2 \tag{3.11}$$

for all $n \in \mathbb{N}$. Therefore $\{Tx_n\}$ is bounded. Note that $\phi(p, K_{r_n}Tx_n) \leq \phi(p, Tx_n)$ for all $n \in \mathbb{N}$. Therefore $\{u_n\} = \{K_{r_n}Tx_n\}$ is also bounded. From $x_{n+1} \in C_{n+1}$, one has

$$\phi(x_n, u_n) + \phi(u_n, Tx_n) \leq \frac{2}{1-k} \langle x_n - x_{n+1}, Jx_n - JTx_n \rangle + 2\langle x_n - x_{n+1}, JTx_n - Ju_n \rangle. \tag{3.12}$$

By Step 5, we obtain that $x_{n+1} - x_n \rightarrow 0$. Taking limit on both sides of (3.12), we obtain $\phi(x_n, u_n) + \phi(u_n, Tx_n) \rightarrow 0$ as $n \rightarrow \infty$. Noting that $0 \leq (\|x_n\| - \|u_n\|)^2 \leq \phi(x_n, u_n)$, $0 \leq (\|u_n\| - \|Tx_n\|)^2 \leq \phi(u_n, Tx_n)$, and $\|x_n\| \rightarrow \|q\|$, it is implied that

$$\|q\| = \lim_{n \rightarrow \infty} \|x_n\| = \lim_{n \rightarrow \infty} \|u_n\| = \lim_{n \rightarrow \infty} \|Tx_n\|, \tag{3.13}$$

and consequently

$$\|Jq\| = \lim_{n \rightarrow \infty} \|Jx_n\| = \lim_{n \rightarrow \infty} \|Ju_n\| = \lim_{n \rightarrow \infty} \|JTx_n\|. \tag{3.14}$$

This implies that $\{J(u_n)\}$ and $\{J(Tx_n)\}$ are bounded. Since E is reflexive, E^* is also reflexive. So we can assume that

$$J(u_n) \longrightarrow f \in E^* \quad (3.15)$$

weakly. On the other hand, in view of the reflexivity of E , one has $J(E) = E^*$, which means that, for $f \in E^*$, there exists $x_f \in E$, such that $Jx_f = f$. It follows that

$$\phi(x_n, u_n) = \|x_n\|^2 - 2\langle x_n, J(u_n) \rangle + \|u_n\|^2 = \|x_n\|^2 - 2\langle x_n, J(u_n) \rangle + \|J(u_n)\|^2. \quad (3.16)$$

Taking $\liminf_{n \rightarrow \infty}$ on both sides of the equality above, we have

$$\begin{aligned} 0 &\geq \|q\|^2 - 2\langle q, f \rangle + \|f\|^2 \\ &= \|q\|^2 - 2\langle u_0, Jx_f \rangle + \|Jx_f\|^2 \\ &= \phi(q, x_f). \end{aligned} \quad (3.17)$$

Therefore $\phi(q, x_f) = 0$ and consequently $q = x_f$, which implies that $f = Jq$. Hence

$$J(u_n) \longrightarrow Jq \in E^* \quad (3.18)$$

weakly. Since $\|J(u_n)\| \rightarrow \|Jq\|$ and E^* has the property (K), we have

$$\|J(u_n) - Jq\| \longrightarrow 0. \quad (3.19)$$

Noting that $J^{-1} : E^* \rightarrow E$ is demicontinuous, we have

$$u_n \longrightarrow q \in E \quad (3.20)$$

weakly. Since $\|u_n\| \rightarrow \|q\|$ and E has the property (K), we obtain that $u_n \rightarrow q$ as $n \rightarrow \infty$. Similarly, it is not difficult to show that $Tx_n \rightarrow q$ as $n \rightarrow \infty$. From $x_n \rightarrow q$ and the closeness property of T , we have $Tq = q$.

Next, we want to show that $q \in \text{GMEP}(\Theta, A, \varphi)$. Define $G : C \times C \rightarrow \mathbb{R}$ by $G(x, y) = \Theta(x, y) + \langle Ax, y - x \rangle + \varphi(y) - \varphi(x)$ for all $x, y \in C$. It is not hard to verify that G satisfies conditions (A1)–(A4). It follows from $u_n = K_{r_n}Tx_n$ and (A2) that

$$\frac{1}{r_n} \langle y - u_n, Ju_n - Jx_n \rangle \geq G(y, u_n), \quad \forall y \in C. \quad (3.21)$$

By using (A4) and $\liminf_{n \rightarrow \infty} r_n > 0$, we obtain $0 \geq G(y, q)$ for all $y \in C$. For $t \in (0, 1]$ and $y \in C$, let $y_t = ty + (1 - t)q$. So, from (A1) and (A4), we have

$$0 = G(y_t, y_t) = G(y_t, ty + (1 - t)q) \leq tG(y_t, y) + (1 - t)G(y_t, q) \leq tG(y_t, y). \quad (3.22)$$

Dividing by t , we have

$$G(y_t, y) \geq 0, \quad \forall y \in C. \quad (3.23)$$

From (A3) we have $0 \leq \lim_{t \rightarrow 0} G(y_t, y) = \lim_{t \rightarrow 0} G(ty + (1-t)q, y) \leq G(q, y)$ for all $y \in C$, and hence $q \in \text{GMEP}(\Theta, A, \varphi)$. So, $q \in F(T) \cap \text{GMEP}(\Theta, A, \varphi) = \Omega$.

Step 7. Show that $q = \Pi_\Omega x_0$.

It follows from Steps 5 and 6 that

$$\phi(q, x_0) \leq \phi(\Pi_\Omega x_0, x_0) \leq \phi(q, x_0), \quad (3.24)$$

which implies that $\phi(\Pi_\Omega x_0, x_0) = \phi(q, x_0)$. Hence, $q = \Pi_\Omega x_0$. Then $\{x_n\}$ converges strongly to $q = \Pi_\Omega x_0$. This completes the proof. $\square$

If T is closed ϕ -quasi-nonexpansive, then Theorem 3.1 is reduced to the following corollary.

Corollary 3.2. *Let E be a reflexive, strictly convex, and smooth Banach space such that E and E^* have the property (K). Assume that C is a nonempty closed convex subset of E . Let $T : C \rightarrow C$ be a ϕ -closed quasi-nonexpansive mapping, Θ a bifunction from $C \times C$ to $\mathbb{R}$ satisfying (A1)–(A4), $\varphi : C \rightarrow \mathbb{R}$ a lower semi-continuous and convex function, and $A : C \rightarrow E^*$ a continuous and monotone mapping such that $\Omega := F(T) \cap \text{GMEP}(\Theta, A, \varphi) \neq \emptyset$. Define a sequence $\{x_n\}$ in C by the following algorithm:*

$x_0 \in E$, chosen arbitrarily,

$C_1 = C$,

$x_1 = \Pi_{C_1}(x_0)$,

$u_n \in C$ such that

$$\Theta(u_n, y) + \langle Au_n, y - u_n \rangle + \varphi(y) - \varphi(u_n) + \frac{1}{r_n} \langle y - u_n, Ju_n - JTx_n \rangle \geq 0, \forall y \in C, \quad (3.25)$$

$C_{n+1} = \{z \in C_n : \phi(x_n, u_n) + \phi(u_n, Tx_n) \leq 2\langle x_n - z, Jx_n - Ju_n \rangle\}$,

$x_{n+1} = \Pi_{C_{n+1}}(x_0)$,

where $r_n > 0$ for all $n \in \mathbb{N}$ with $\liminf_{n \rightarrow \infty} r_n > 0$. Then $\{x_n\}$ converges strongly to $\Pi_\Omega(x_0)$.

If $E = H$ is a Hilbert space, then Theorem 3.1 is reduced to the following corollary.

Corollary 3.3. *Let H be a Hilbert space. Assume that C is a nonempty closed convex subset of H . Let $T : C \rightarrow C$ be a closed and ϕ -quasi-strict pseudocontraction, Θ a bifunction from $C \times C$ to $\mathbb{R}$ satisfying (A1)–(A4), $\varphi : C \rightarrow \mathbb{R}$ a lower semi-continuous and convex function, and $A : C \rightarrow H$*

a continuous and monotone mapping such that $\Omega := F(T) \cap \text{GMEP}(\Theta, A, \varphi) \neq \emptyset$. Define a sequence $\{x_n\}$ in C by the following algorithm:

$x_0 \in H$, chosen arbitrarily,

$C_1 = C$,

$x_1 = \Pi_{C_1}(x_0)$,

$u_n \in C$ such that,

$$\Theta(u_n, y) + \langle Au_n, y - u_n \rangle + \varphi(y) - \varphi(u_n) + \frac{1}{r_n} \langle y - u_n, u_n - Tx_n \rangle \geq 0, \quad \forall y \in C, \quad (3.26)$$

$$C_{n+1} = \left\{ z \in C_n : \|x_n - u_n\|^2 + \|u_n - Tx_n\|^2 \leq \frac{2}{1-k} \langle x_n - z, x_n - Tx_n \rangle + 2 \langle x_n - z, Tx_n - u_n \rangle \right\},$$

$x_{n+1} = \Pi_{C_{n+1}}(x_0)$,

where $k \in [0, 1)$ and $r_n > 0$ for all $n \in \mathbb{N}$ with $\liminf_{n \rightarrow \infty} r_n > 0$. Then $\{x_n\}$ converges strongly to $\Pi_\Omega(x_0)$.

If $A = 0$ and $\varphi = 0$, then we have the following corollary.

Corollary 3.4. Let E be a reflexive, strictly convex, and smooth Banach space such that E and E^* have the property (K) . Assume that C is a nonempty closed convex subset of E . Let $T : C \rightarrow C$ be a closed and ϕ -quasi-strict pseudocontraction and Θ a bifunction from $C \times C$ to $\mathbb{R}$ satisfying (A1)–(A4) such that $\Lambda := F(T) \cap \text{EP}(\Theta) \neq \emptyset$. Define a sequence $\{x_n\}$ in C by the following algorithm:

$x_0 \in E$, chosen arbitrarily,

$C_1 = C$,

$x_1 = \Pi_{C_1}(x_0)$,

$u_n \in C$ such that

$$\Theta(u_n, y) + \frac{1}{r_n} \langle y - u_n, Ju_n - JT x_n \rangle \geq 0 \quad \forall y \in C, \quad (3.27)$$

$$C_{n+1} = \left\{ z \in C_n : \phi(x_n, u_n) + \phi(u_n, Tx_n) \leq \frac{2}{1-k} \langle x_n - z, Jx_n - JT x_n \rangle + 2 \langle x_n - z, JT x_n - Ju_n \rangle \right\},$$

$x_{n+1} = \Pi_{C_{n+1}}(x_0)$,

where $k \in [0, 1)$ and $r_n > 0$ for all $n \in \mathbb{N}$ with $\liminf_{n \rightarrow \infty} r_n > 0$. Then $\{x_n\}$ converges strongly to $\Pi_\Omega(x_0)$.

Corollary 3.5 ([25, Theorem 3.1]). *Let E be a reflexive, strictly convex and smooth Banach space such that E and E^* have the property (K). Assume that C is a nonempty closed convex subset of E . Let $T : C \rightarrow C$ be a ϕ -closed quasi-strict pseudocontraction. Define a sequence $\{x_n\}$ in C by the following algorithm:*

$$\begin{aligned}
 & x_0 \in E, \text{ chosen arbitrarily,} \\
 & C_1 = C, \\
 & x_1 = \Pi_{C_1}(x_0), \\
 & u_n \in C \text{ such that} \\
 & C_{n+1} = \left\{ z \in C_n : \phi(x_n, Tx_n) \leq \frac{2}{1-k} \langle x_n - z, Jx_n - JT x_n \rangle \right\}, \\
 & x_{n+1} = \Pi_{C_{n+1}}(x_0)
 \end{aligned} \tag{3.28}$$

where $k \in [0, 1)$. Then $\{x_n\}$ converges strongly to $\Pi_\Omega(x_0)$.

Proof. Put $\Theta = 0$, $A = 0$, $\varphi = 0$, and $r_n = 1$ for all $n \geq 1$ in Theorem 3.1. Then, $K_{r_n} = \Pi_C$ for all $n \geq 1$. So, $u_n = \Pi_C T x_n$ for all $n \geq 1$ (note that $x_1 = \Pi_C x_0$). Since $x_n = \Pi_{C_n} x_0 \in C_n \subset C$ and then $T x_n \in C$ for all $n \geq 1$, we have $u_n = T x_n$ for all $n \geq 1$. Thus $\phi(x_n, u_n) + \phi(u_n, T x_n) = \phi(x_n, T x_n)$ and $J T x_n - J u_n = 0$ for all $n \geq 1$. For this reason, (1.12) is a special case of (3.1). Applying Theorem 3.1, we have the desired result. $\square$

Remark 3.6. It is well known that every uniformly convex and uniformly smooth Banach space satisfies all assumptions of Banach space in Theorem 3.1. On the other hand, in general, Musielak-Orlicz space [26] need not be uniformly convex or uniformly smooth, however, any strictly convex, reflexive and smooth Musielak-Orlicz space [26] satisfies all Banach-space assumptions of Theorem 3.1. It can be written as the following diagram:

For this reason, Theorem 3.1 can be viewed as a more general one and can be applied widely in both the fixed point problems and the equilibrium problems.
