We constructed three two-step semi-implicit hybrid methods (SIHMs) for solving oscillatory second order ordinary differential equations (ODEs). The first two methods are three-stage fourth-order and three-stage fifth-order with dispersion order six and zero dissipation. The third is a four-stage fifth-order method with dispersion order eight and dissipation order five. Numerical results show that SIHMs are more accurate as compared to the existing hybrid methods, Runge-Kutta Nyström (RKN) and Runge-Kutta (RK) methods of the same order and Diagonally Implicit Runge-Kutta Nyström (DIRKN) method of the same stage. The intervals of absolute stability or periodicity of SIHM for ODE are also presented.

1. Introduction

Second-order ordinary differential equations (ODEs) which are oscillatory in nature often arise in many scientific areas of engineering and applied sciences such as celestial mechanics, molecular dynamics, and quantum mechanics. Consider the numerical solution of the initial value problem (IVP) for second-order ODEs in the form

\[
y'' = f(t, y), \quad y(t_0) = y_0, \quad y'(t_0) = y'_0, \tag{1}
\]

in which the first derivative does not appear explicitly. Apparently, some of the most common methods used for solving second-order ODEs numerically are Runge-Kutta Nyström (RKN) and Runge-Kutta methods for Runge-Kutta method the IVPs need to be reduced to a system of first-order ODEs twice the dimension. The IVP can be solved using a particular explicit hybrid algorithms which were developed by Franco [1] or a multistep method for special second-order ODEs as in Yap et al. [2]. Franco [3] proposed that (1) can be solved using a particular explicit hybrid algorithms or special multistep methods for second-order ODEs. Franco [3] constructed explicit two-step hybrid methods of order four up to order six for solving second-order IVPs by considering the local truncation error and order conditions developed by Coleman [4].

Most of the IVPs represented by (1) have solutions which are oscillatory in nature, making it difficult to get the accurate numerical results. To address the problem several authors [5–7] focused their research on developing methods with reduced phase lag and dissipation, where phase-lag or dispersion error is the difference of the angle for the computed solution and the exact solution and dissipation is the distance of the computed solution from the standard cyclic solution. The analysis of phase-lag or dispersion errors was first introduced by Brusa and Nigro [8]. Van der Houwen and Sommeijer [9] proposed explicit RKN methods of order four, five, and six with reduced phase-lag of order \( q = 6, 8, 10 \), respectively. Senu et al. [7, 10] developed diagonally implicit RKN method with dispersion of higher order for solving oscillatory problems. In a related work Kosti et al. [11] constructed an optimized RKN method (OPRKN) based on the existing explicit four-stage fifth-order RKN method for the integration of oscillatory IVPs. In his derivation he used the phase-lag, amplification factor and the first derivative of the amplification factor by equating them to zero. Later, Kosti et al. [12] also developed an OPRKN method based on the same explicit RKN method, in which he used the phase lag, amplification factor, and the first
derivative of the phase-lag properties instead of using only the first derivative of amplification factor in his previous work.

In this paper, we constructed three-stage fourth-order and three-stage fifth-order methods with dispersion order six and zero dissipation and also four-stage fifth-order method with dispersion order eight and dissipation order five. It is done by taking the dispersion relations for the semi-implicit hybrid methods and solving them together with the algebraic conditions of the methods. The intervals of stability of the methods are also presented. Finally, numerical tests on second-order differential equation for oscillatory problems are given.

2. Analysis Phase Lag of the Methods

An s-stage two-step hybrid method for the numerical integration of the IVP(I) is of the form

\[
Y_i = (1 + c_i) y_n - c_i y_{n-1} + h^2 \sum_{j=1}^{s} a_{ij} f \left( t_n + c_j h, Y_j \right), \\
i = 1, \ldots, s, \\
y_{n+1} = 2y_n - y_{n-1} + h^2 \sum_{j=1}^{s} b_j f \left( t_n + c_j h, Y_j \right),
\]

where \( b_j, c_i \), and \( a_{ij} \) can be represented in Butcher notation by the table of coefficients as follows:

\[
\begin{bmatrix}
c & A \\
b^T
\end{bmatrix} = \begin{bmatrix}
c_1 & a_{1,1} & \cdots & a_{1,s} \\
\vdots & \vdots & \ddots & \vdots \\
c_s & a_{s,1} & \cdots & a_{s,s} \\
\end{bmatrix}
\]

The methods of the form (2) are defined by

\[
Y_1 = y_{n-1}, \quad Y_2 = y_n, \\
y_i = \left(1 + c_i\right) y_n - c_i y_{n-1} + h^2 \sum_{j=1}^{s} a_{ij} f \left( t_n + c_j h, Y_j \right), \\
i = 3, \ldots, s, \\
y_{n+1} = 2y_n - y_{n-1} + h^2 \left[ b_1 f_{n-1} + b_2 f_n + \sum_{i=3}^{s} b_i f \left( t_n + c_i h, Y_i \right) \right],
\]

where \( f_{n-1} = f(t_{n-1}, y_{n-1}), f_n = f(t_n, y_n), h = \Delta t = t_{n+1} - t_n \) and the first two nodes are \( c_1 = -1 \) and \( c_2 = 0 \). The method only requires to evaluate \( f(t_n, y_n), f(t_n + c_j h, Y_j), \ldots, f(t_n + c_j h, Y_e) \) for each step after the starting procedure. This method is considered as a two-step hybrid method with \( s-1 \) stages per step and the semi-implicit hybrid with the diagonal elements being equal can be written in Butcher tableau as follows:

\[
\begin{bmatrix}
-1 & a_{3,1} & a_{3,2} & \gamma \\
\vdots & \vdots & \ddots & \vdots \\
\gamma & c_1 & a_{2,1} & a_{2,2} & \cdots & a_{2,s} & \cdots & a_{s-1,1} & \gamma \\
\end{bmatrix} \begin{bmatrix} b_1 \\
\vdots \\
\vdots \\
\vdots \\
b_{s-1} \\
b_s
\end{bmatrix}
\]

Phase analysis can be divided into two parts. First is the inhomogeneous part, in which the phase error is constant in time and second is the homogeneous one, in which the phase error is accumulated as \( n \) increases. As proposed by Franco [3], the phase analysis is investigated using the second-order homogeneous linear test model

\[
y''(t) = -\lambda^2 y(t) \quad \text{for} \quad \lambda > 0, \lambda \in \mathbb{R}. \tag{8}
\]

Alternatively when (2) are applied to (8), they can be written in vector form as

\[
Y = (e + c) y_n - c y_{n-1} - H^2 AY, \tag{9}
\]

\[
y_{n+1} = 2y_n - y_{n-1} - H^2 b^T Y, \tag{10}
\]

where \( H = \lambda h, Y = (Y_1, \ldots, Y_s)^T, c = (c_1, \ldots, c_s)^T \), and \( e = (1, \ldots, 1)^T \). From (9) we obtain

\[
Y = \left(1 + H^2 A \right)^{-1} (e + c) y_n - \left(1 + H^2 A \right)^{-1} c y_{n-1}. \tag{11}
\]

Substituting (II) into (10), the following recursion relation is obtained:

\[
y_{n+1} - S\left(H^2\right) y_n + P\left(H^2\right) y_{n-1} = 0, \tag{12}
\]

where

\[
S\left(H^2\right) = 2 - H^2 b^T \left(1 + H^2 A\right)^{-1} (e + c), \tag{13}
\]

\[
P\left(H^2\right) = 1 - H^2 b^T \left(1 + H^2 A\right)^{-1} c.
\]

Solving the difference system (12), the computed solution is given by

\[
y_n = 2|c| |\rho|^n \cos(\omega + n\chi), \tag{14}
\]

where \( \rho \) is the amplification factor, \( \phi \) is the phase, \( \omega \) and \( c \) are real constants determined by \( y_0 \) and \( y_0' \) and the hybrid parameters. The exact solution of (8) is given by

\[
y(t_n) = 2|\sigma| \cos(\chi + nh), \tag{15}
\]

where \( n \) is the number of term, \( \sigma \) and \( \chi \) are real constants determined by initial conditions. Equations (14) and (15) led to the following definition.

Definition 1 (phase lag). Apply the hybrid method (2) to (8). Next we define the phase lag \( \varphi(H) = H - \phi \). If \( \varphi(H) = O(H^{m+1}) \), and then the hybrid method is said to have phase-lag order \( q \). Additionally, the quantity \( d(H) = 1 - |\rho| \) is called amplification error. If \( d(H) = O(H^{r+1}) \), then the hybrid method is said to have dissipation order \( r \).
From Definition 1, it follows that

\[ \varphi(H) = H - \cos^{-1}\left( \frac{S(H^2)}{\sqrt{P(H^2)}} \right), \quad \text{(16)} \]

\[ d(H) = 1 - \sqrt{P(H^2)} \]

Let us denote \( S(H^2) \) and \( P(H^2) \) to be the following:

\[ S(H^2) = \frac{2 + \sum_{i=1}^{s-1} \alpha_i H^{2i}}{(1 + \gamma H^2)^{s-2}}, \]

\[ P(H^2) = \frac{1 + \sum_{i=1}^{s-1} \beta_i H^{2i}}{(1 + \gamma H^2)^{s-2}}. \quad \text{(17)} \]

Based on the definition of phase lag, the dispersion relations are developed. For a zero dissipative method with three-stage \((s=3)\), the dispersion relation of order six \((q=6)\) is given by the following:

**Order 6:**

\[ \alpha_2 = \frac{1}{y} \left( \frac{1}{360} - y^2 \right), \quad \text{(18)} \]

and the dispersion relations up to order eight for \( s = 4 \) are given by

**Order 6:**

\[ \beta_3 - 2\beta_2 y - \alpha_3 + \gamma \alpha_2 - \frac{3}{2} y^2 + \frac{1}{360} - 2y^3, \quad \text{(19)} \]

**Order 8:**

\[ \frac{1}{4} \beta_2^3 - \left( \frac{7}{2} y^2 + y + \frac{1}{24} \right) \beta_2 - \gamma \alpha_3 + y^2 \alpha_2 + \left( 2y + \frac{1}{7} \right) \beta_3 = \frac{1}{20160} - \frac{1}{24} y^2 - 2y^3 - \frac{13}{4} y^4. \quad \text{(20)} \]

The following quantity is used to determine that the dissipation constant of the formula for \( s = 3, 4 \) is

(i) for \( s = 3 \)

\[ 1 - \sqrt{P(H^2)} = \left( -\frac{1}{2} \beta_1 + \frac{1}{2} y \right) H^2 \]

\[ + \left( \frac{1}{2} \beta_2 - \frac{1}{4} \gamma \beta_1 - \frac{3}{8} y^2 + \frac{1}{8} \beta_1^2 \right) H^4 \]

\[ + \left( \frac{1}{4} \gamma \beta_2 - \frac{3}{16} y \beta_1 + \frac{5}{16} y^3 + \frac{1}{4} \beta_1 \beta_2 - \frac{1}{16} y \beta_1^2 - \frac{1}{16} \beta_1 \beta_2 \right) H^6 \]

\[ + \left( \frac{5}{128} \beta_3^2 - \frac{3}{16} y \beta_2 + \frac{5}{32} y^3 \beta_1 + \frac{3}{64} y^2 \beta_2^2 + \frac{1}{8} \beta_2 y^2 \beta_3 - \frac{3}{16} \beta_2 \beta_3 + \frac{1}{32} \beta_3 y^3 \right) H^8 + O(H^{10}), \quad \text{(21)} \]

(ii) for \( s = 4 \)

\[ 1 - \sqrt{P(H^2)} = \left( y - \frac{1}{2} \beta_1 \right) H^2 \]

\[ + \left( \frac{1}{2} \beta_1 y - y^2 - \frac{1}{2} \beta_2 + \frac{1}{8} \beta_1^2 \right) H^4 \]

\[ + \left( -\frac{1}{2} \beta_1 y + \frac{1}{2} \beta_2 y + y^3 - \frac{1}{2} \beta_3 - \frac{1}{8} \beta_2^2 \right) H^6 \]

\[ + \left( -y^4 + \frac{1}{2} \beta_1 y^3 - \frac{1}{2} \beta_2 y^3 \right) H^8 \]

\[ + \left( \frac{1}{2} \beta_2 y + \frac{1}{4} \beta_1 \beta_2 y + \frac{1}{8} \beta_2^2 \right) y^2 \]

\[ + \left( \frac{1}{4} \beta_1 \beta_3 + \frac{1}{8} \beta_2^2 + \frac{1}{16} \beta_1 \gamma \right) \]

\[ - \frac{3}{16} \beta_1 \beta_2 + \frac{5}{128} \beta_3^2 \right) H^8 + O(H^{10}). \quad \text{(22)} \]

From (12), the stability polynomial of hybrid method can be written as

\[ \xi^2 - S(H^2) \xi + P(H^2) = 0. \quad \text{(23)} \]

The numerical solution defined by (12) should be periodic. The necessary conditions are

\[ P(H^2) \equiv 1, \quad |S(H^2)| < 2, \quad \forall H^2 \in (0, H_s^2), \quad \text{(24)} \]

and interval \((0, H_s^2)\) is known as the periodicity interval of the method. The method is called zero dissipative when \( d(H) = 0 \), that is, if it satisfies conditions (16). Otherwise, as the method possesses a finite order of dissipation, the integration process is stable if the coefficients of polynomial in (23) satisfy the conditions

\[ P(H^2) < 1, \quad |S(H^2)| < 1 + P(H^2), \quad \forall H^2 \in (0, H_s^2), \quad \text{(25)} \]

and interval \((0, H_s^2)\) is known as the interval of absolute stability of the method.

**3. Construction of the Methods**

In this section, the fourth- and fifth-order SIHMs which require only three and four stages respectively are obtained. The derivations of the methods are based on the order conditions, dispersive and dissipative error, and minimization of the error constant \( C_{p+1} \) of the method. The error constant is defined by

\[ C_{p+1} = \left\| (e_{p+1}(t_1), \ldots, e_{p+1}(t_k)) \right\|_2, \quad \text{(26)} \]

where \( k \) is the number of trees of order \( p + 2(p(t_i) = p + 2) \), for the \( p \)-th order method and \((e_{p+1}(t_i))\) is the local truncation error defined in Coleman [4].
The Order conditions of hybrid method given in [4] are
Order 2
\[ \sum b_i = 1, \quad (27) \]
Order 3
\[ \sum b_i c_i = 0, \quad (28) \]
Order 4
\[ \sum b_i c_i^2 = \frac{1}{6}, \quad \sum b_i a_j = \frac{1}{12}, \quad (29) \]
Order 5
\[ \sum b_i c_i^4 = 0, \quad \sum b_i c_i a_j = \frac{1}{12}, \quad \sum b_i a_j c_j = 0, \quad (30) \]
Order 6
\[ \sum b_i c_i^6 = 0, \quad \sum b_i c_i^2 a_j = \frac{1}{30}, \quad \sum b_i c_i c_j = -\frac{1}{60}, \quad (31) \]
For the method, \( c_i \) need to satisfy
\[ \sum a_j = \frac{1}{2} (c_i^2 + c_i), \quad (i = 1, \ldots, s). \quad (32) \]

3.1. SIHM with Three Stages. To derive the fourth-order SIHM method, we use the algebraic conditions up to order four (27)–(29), simplifying condition (32), zero dissipation conditions \( (\beta_1 = \gamma, \beta_2 = 0) \), and dispersion relation of order six \( (q = 6) \), (19). The resulting system of equations consists of five nonlinear equations with seven unknown variables to be solved. Therefore, we have two degrees of freedom. The coefficients of the methods are determined in terms of the arbitrary parameters \( c_i \) and \( a_{33} \) which are given by the expressions

\[ b_1 = \frac{1}{6 + 6c_3}, \quad b_2 = \frac{6c_3 - 1}{6c_3}, \quad b_3 = \frac{1}{6c_3 (1 + c_3)}, \]
\[ a_{31} = -c_3 \left( 30a_{33}c_3 - c_3 - 1 \right), \quad (33) \]
\[ a_{32} = \frac{7}{15} c_3^2 + a_{33} c_3^2 + \frac{7}{15} c_3 - a_{33}. \]

By minimizing the error constant from (26) we have \( c_3 = 9/10 \) and \( a_{33} = 1/30 \). This method is denoted as SIHM3(4) which is given below:

\[
\begin{array}{cccc}
-1 & 0 & 0 & 0 \\
0 & 0 & 19 & 1 \\
9 & 24 & 100 & 30 \\
5 & 22 & 50 & 57 \\
57 & 27 & 513 & \\
\end{array}
\]

With this solution, the norms of the principal local truncation error coefficient for \( y_n \) are given by
\[ \| r^{(5)} \|_2 = 1.863 \times 10^{-2}, \quad (35) \]

3.2. SIHM Order Five with Four Stages. The SIHM method of order five is obtained by considering the order conditions up to order five which are (27) to (30) and (32) together with dispersion relations up to order eight, ((19) and (20)). Solving all the conditions simultaneously, and then the following family of solutions in terms of free parameters \( a_{41} \) and \( b_3 \) is obtained:

\[ a_{31} = \frac{360a_{41}b_3 - 30a_{41} + 1}{360b_3}, \]
\[ a_{32} = -\frac{360a_{41}b_3 + 30a_{41} - 1 + 360b_3^2 + 330b_3}{360b_3}, \]
\[ a_{42} = \frac{-360a_{41}b_3 + 30a_{41} - 29 + 360b_3^2 + 330b_3}{30 (12b_3 - 1)}, \]
\[ a_{43} = -\frac{-1 + 20b_3}{20 (12b_3 - 1)}, \]
\[ a_{33} = -b_3 + \frac{1}{12}, \quad a_{44} = -b_3 + \frac{1}{12}. \]

\[ b_1 = \frac{1}{12}, \quad b_2 = \frac{5}{6}, \quad b_4 = -b_3 + \frac{1}{12}, \]
\[ c_3 = 1, \quad c_4 = 1. \]
Table 1: Summary of the properties of the SIHM3(4), SIHM3(5), and SIHM4(5) methods.

Note that DPC is dispersion constant, DSC is dissipation constant, PI is periodicity interval, and S.I is stability interval.

By minimizing the error norm expression, we have \( a_{k1} = 150617/771120 \) and \( b_k = 23/324 \).

With this solution, the norm of the principal local truncation error coefficient for \( y_n \) is given by

\[
\|e(6)\|_2 = 9.772 \times 10^{-2}.
\]

This fifth-order formula is dispersive order eight and dissipative order five with dispersion and dissipation constants \( \frac{150617}{771120} \) and \( \frac{23}{324} \) respectively. This method is denoted as SIHM4(5), the coefficients are given below (see: The SIHM4(5) method) and the interval of absolute stability of the method is \((0, 5.75)\).

4. Problems Tested and Numerical Results

In this section, SIHM3(4) is compared with five other fourth-order methods: DIRKN three-stage fourth-order derived by Senu et al. [10], DIRKN three-stage fourth-order derived by Sommeijer [13], Classical Runge-Kutta fourth-order given in Dormand [14], explicit three-stage fourth-order hybrid method derived by Franco [3], and Classical RKN fourth order given in Hairer et al. [15]. The fifth-order methods, SIHM3(5) and SIHM4(5) are compared with four other methods: DIRKN four-stage fourth-order derived by Senu et al. [7], Classical Runge-Kutta fifth order derived by Butcher [16], explicit four-stage fifth-order hybrid method derived by Franco [3], and Classical RKN fifth-order method given from Hairer et al. [15]. All the problems were executed for \( t_{end} = 10^6 \) except for Orbital problem \( t_{end} = 100 \). The test problems used are listed below.

#### Problem 1 (Chawla and Rao [17]). We have

\[
y''(t) = -100y(t), \quad y(0) = 1, \quad y'(0) = -2.
\]

Exact solution is \( y = - (1/5) \sin(10t) + \cos(10t) \)

#### Problem 2 (Attili et al. [18]). We have

\[
y''(t) = -64y(t), \quad y(0) = \frac{1}{4}, \quad y'(0) = -\frac{1}{2}.
\]

Exact solution is \( y = (\sqrt{17}/16) \sin(8t + \theta), \quad \theta = \pi - \tan^{-1}(4) \)

#### Problem 3 (Lambert and Watson [5]). We have

\[
\begin{align*}
\frac{d^2 y_1(t)}{dt^2} &= -y_1(t) + y_2(t) + y_3(t), \\
\frac{d^2 y_2(t)}{dt^2} &= -y_2(t) + \frac{3}{8}y_1(t) + y_3(t), \\
\end{align*}
\]

Exact solution is \( y_1(t) = a \cos(\sqrt{5}t) + f(t), \quad y_2(t) = a \sin(\sqrt{5}t) + f(t), \quad \) and \( f(t) \) is chosen to be \( e^{-0.05t} \) and parameters \( a \) and \( \nu \) are 20 and 0.1 respectively.

#### Problem 4 (an almost periodic orbit problem given in Stiefel and Bettis [19]). We have

\[
\begin{align*}
y_1''(t) + y_1(t) &= 0.001 \cos(t), \\
y_1(0) &= 1, \quad y_1'(0) = 0, \\
y_2''(t) + y_2(t) &= 0.001 \sin(t), \\
y_2(0) &= 0, \quad y_2'(0) = 0.9995.
\end{align*}
\]

Exact solution is \( y_1 = \cos(t) + 0.0005\sin(t), \quad y_2 = \sin(t) - 0.0005t \cos(t) \)

#### Problem 5 (inhomogeneous system studied by Franco [1]). We have

\[
\begin{align*}
y''(t) + \begin{pmatrix} 13 & -12 \\ -12 & 13 \end{pmatrix} y(t) &= \begin{pmatrix} g_1(t) \\ g_2(t) \end{pmatrix}, \\
y(0) &= \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad y'(0) = \begin{pmatrix} -4 \\ 8 \end{pmatrix}, \\
g_1(t) &= 9 \cos(2t) - 12 \sin(2t), \\
g_2(t) &= -12 \cos(2t) + 9 \sin(2t).
\end{align*}
\]

Exact solutions are

\[
y(t) = \begin{pmatrix} \sin(t) - \sin(5t) + \cos(2t) \\ \sin(t) + \sin(5t) + \cos(2t) \end{pmatrix}.
\]
Problem 6 (Allen and Wing [20]). We have
\[ y''(t) = -y(t) + t, \quad y(0) = 1, \quad y'(0) = 2. \] (47)
Exact solution is \( y = \sin(t) + \cos(t) + t. \)

Problem 7 (inhomogeneous problem studied by Papadopoulos et al. [21]). We have
\[ y''(t) = -v^2 y(t) + \left(v^2 - 1\right) \sin(t), \]
\[ y(0) = 1, \quad y'(0) = v + 1, \] (48)
where \( v \gg 1. \)

Exact solution is \( y(t) = \cos(vt) + \sin(vt) + \sin(t). \)
Numerical result is for the case \( v = 10. \)

Problem 8 (orbital problem studied by van der Houwen and Sommeijer [22]). We have
\[ y_1''(t) = -4t^2 y_1 - \frac{2y_2}{\sqrt{y_1^2 + y_2^2}}, \] (49)
\[ y_1(t_0) = 0, \quad y_1'(t_0) = -\sqrt{2\pi}, \]
\[ y_2''(t) = -4t^2 y_2 + \frac{2y_1}{\sqrt{y_1^2 + y_2^2}}, \] (50)
\[ y_2(t_0) = 1, \quad y_2'(t_0) = 0, \quad \sqrt{\frac{\pi}{2}} \leq t \leq t_{\text{end}}. \]

Exact solution is \( y_1(t) = \cos(t^2), \quad y_2(t) = \sin(t^2) \)
The following notations are used in Figures 1–16.

(i) SIHM3(4): a semi-implicit hybrid method of order four with dispersive order six and zero dissipation.

(ii) SIHM3(5): a semi-implicit hybrid method of order five with dispersive order six and zero dissipation.

(iii) SIHM4(5): a semi-implicit hybrid method of order five with dispersive order eight and dissipative order five.

(iv) DIRKN(S1): a three-stage fourth-order dispersive order six method with “small” dissipation constant and principal local truncation errors derived by Senu et al. [7].

(v) DIRKN(HS): a three-stage fourth-order derived by Sommeijer [13].

(vi) DIRKN(S2): a four-stage fourth-order dispersive order eight method with “small” dissipation constant derived by Senu et al. [10].

(vii) RKN4: a classical RKN method order four in [14].

(viii) RK4: a classical RK method order four in [14].

(ix) RKN5: a five-stage fifth-order RKN method derived by Butcher [16].

(x) RK6: a seven-stage sixth-order RK method derived by Hairer et al. [15].
In order to evaluate the effectiveness of the semi-implicit hybrid methods, we solved several problems which have oscillatory solutions. To make a comparison of SIHM and other existing methods, one measure of the accuracy is examined using the absolute error which is defined by

$$\text{Absolute error} = \max \left\{ \left| y(t_n) - y_n \right| \right\}, \quad (51)$$

where $y(t_n)$ is the exact solution and $y_n$ is the computed solution.

For comparison purposes, in analyzing the numerical results, methods of the same order will be compared. The results are given in Figures 1–16. We present the efficiency curves where the common logarithm of the maximum global error along the integration versus the CPU time is taken. From Figures 1, 2, 3, 4, 5, 6, 7, and 8, we observed that the new SIHM(4) is the most efficient for integrating second-order differential equations possessing oscillatory solutions, followed by diagonally implicit DIRKN(S1), original explicit hybrid method EXHBRD4, and other methods like DIRKN(HS), RKN4, and RK4.
From Figures 9, 10, 11, 12, 13, 14, 15, and 16, for the fifth-order methods we observed that SIHM4(5) is the most efficient, followed by SIHM3(5) and EXHBRD5 and the rest of the methods. Even though the new methods are semi-implicit and fairly expensive in terms of time consumed, they are still more efficient compared to the explicit counterpart.

5. Conclusion

In this paper three-stage semi-implicit hybrid methods of order four and five are developed and denoted by SIHM3(4) and SIHM3(5), respectively, they have dispersion order six and zero dissipation. We also developed method of four-stage and fifth order denoted by SIHM4(5) which has dispersion order eight and dissipation order five. All the three methods developed are suitable for solving second-order IVPs which are oscillatory in nature. From the efficiency curves shown in Figures 1–16, we can conclude that all the methods are very efficient compared to the well-known existing methods of the same order in the scientific literature.
