We introduce impulsive cellular neural network models with piecewise alternately advanced and retarded argument (in short IDEPCA). The model with the advanced argument is system with strong anticipation. Some sufficient conditions are established for the existence and global exponential stability of a unique equilibrium. The approaches are based on employing Banach's fixed point theorem and a new IDEPCA integral inequality of Gronwall type. The criteria given are easily verifiable, possess many adjustable parameters, and depend on impulses and piecewise constant argument deviations, which provides exibility for the design and analysis of cellular neural network models. Several numerical examples and simulations are also given to show the feasibility and effectiveness of our results.

1. Introduction

Chua and Yang [1] proposed a novel class of information-processing systems called cellular neural networks (CNNs) in 1988. Like neural networks, it is a large-scale nonlinear analog circuit which processes signals in real time. Like cellular automata [2] it is made of a massive aggregate of regularly spaced circuit clones, called cells, which communicate with each other directly only through its nearest neighbors. Each cell is made of a linear capacitor, a nonlinear voltage-controlled current source, and a few resistive linear circuit elements. The key features of neural networks are asynchronous parallel processing and global interaction of network elements. Impressive applications of neural networks have been proposed for various fields such as optimization, linear and nonlinear programming, associative memory, pattern recognition, and computer vision. For the circuit diagram and connection pattern implementing the CNN, one can refer to [1]. The CNN can be applied in signal processing and can also be used to solve some image processing and pattern recognition problems [3]. However, it is necessary to solve some dynamic image processing and

pattern recognition problems by using delayed cellular neural networks (DCNN) [4–6]. The study of the stability of CNN and DCNN is known to be an important problem in theory and applications.

On the other hand, in real world, many evolutionary processes are characterized by abrupt changes at certain time. These changes are known to be impulsive phenomena, which are included in many fields such as physics, chemistry, population dynamics, and optimal control. Fundamental theory of impulsive differential equations has been developed in [7]. Furthermore, researches of impulsive differential equations have been received much interesting in recent years [8–18]. Meanwhile, several kinds of neural networks with impulse have been investigated. In particular, Xu and Yang established the delay differential inequalities with impulsive initial conditions; some new sufficient conditions for global exponential stability of impulsive delay model were obtained [15, 16].

Most neural networks can be classified into two types, continuous or discrete. However, many real-world systems and natural processes cannot be categorized into one of them. They display characteristics both continuous and discrete

styles. For instance, some biological neural networks in biology, bursting rhythm models in pathology, and optimal control models in economics are characterized by abrupt changes of state. These are the familiar impulsive phenomena.

It is well known that applications of CNN depend crucially on the dynamical behavior of the networks. In these applications, stability and convergence of neural networks are prerequisites. However, in the design of neural networks one is interested not only in the uniform asymptotic stability but also in the global exponential stability, which guarantees a neural network to converge fast enough in order to achieve fast response. In addition, in the analysis of dynamical neural networks for parallel computation and optimization, to increase the rate of convergence to the equilibrium point of the networks and reduce the neural computing time, it is necessary to ensure a desired exponential convergence rate of the networks' trajectories, starting from arbitrary initial states to the equilibrium point which corresponds to the optimal solution. Thus, from the mathematical and engineering points of view, it is required that the neural networks have a unique equilibrium point which is globally exponentially stable. Therefore, the problem of stability analysis has received great attention and many results on this topic have been reported in the literature. See, for instance, [4, 9, 13, 19–27] and references cited therein.

1.1. Piecewise Constant Impulsive Systems. Differential equations with piecewise constant argument (in short DEPCA) are first considered by Shah and Wiener [28] and Cooke and Wiener [29] in the 80s and have been developed by many authors. Applications of DEPCAs are discussed in [30]. Theory and practice of DEPCA of general type, have been discussed extensively in [31–37]. Piecewise constant systems exist in widely expanded areas such as biomedicine, chemistry, mechanical engineering, and physics. The systematical studies with mathematical models involving piecewise constant arguments were initiated for solving some biomedical problems. These kinds of equations are similar in structure to those found in certain sequential-continuous models of disease dynamics. In [38], the following system of equations describing the dynamics of the disease for generation $n = 1, 2, \dots$ is investigated:

$$\begin{aligned} \frac{dI^{(n)}}{dt}(t) &= -c(t)I^{(n)}(t) + k(t)S^{(n)}(t)I^{(n)}(t), \\ n < t \leq n+1, \\ \frac{dS^{(n)}}{dt}(t) &= -c(t)S^{(n)}(t) - k(t)S^{(n)}(t)I^{(n)}(t), \\ n < t \leq n+1, \end{aligned} \quad (1)$$

while

$$I^{(1)}(1) = I_0, \quad S^{(1)}(1) = S_0, \quad (2)$$

where c is the death rate and k is the horizontal transmission factor. These types of models are special cases of the general form

$$\begin{aligned} \frac{dx(t)}{dt} &= F(t, x_t), \quad [t] < t \leq [t] + 1, \quad x_{[t]} = \phi_{[t]}, \\ \phi_{[t]} &= G([t], x_{[t]}), \quad [t] \geq 2, \quad \phi_1 = H, \end{aligned} \quad (3)$$

which arise naturally in a number of models of epidemic. DEPCAs usually describe hybrid dynamical systems (a combination of continuous and discrete) and so combine properties of both differential and difference equations.

Impulsive differential equations with discontinuous argument are proposed as an open problem by Wiener [30] in 1994, namely, the impulsive differential equations with piecewise constant argument: IDEPCA. As we know, impulsive differential equations with piecewise constant arguments (in short IDEPCA) are studied in a few papers [8, 39, 40].

1.2. Model Description. First, let us give a general description of the mathematical model of ICNNs with piecewise alternately advanced and retarded argument:

$$\begin{aligned} \frac{dx_i(t)}{dt} &= -a_i x_i(t) \\ &+ \sum_{j=1}^n \left\{ b_{ij} f_j(x_j(t)) + c_{ij} g_j \left(x_j \left(m \left[\frac{t+l}{m} \right] \right) \right) \right\} \\ &+ d_i, \quad t \neq mk - l, \end{aligned} \quad (4a)$$

$$\Delta x_i|_{t=mk-l} = J_{ik}(x_i(mk-l^-)), \quad i = 1, 2, \dots, n, \quad k \in \mathbb{N}, \quad (4b)$$

where $[\cdot]$ signifies the greatest integer function, l and m are positive real numbers such that $l < m$, $t, x_i \in \mathbb{R}^+$, $i = 1, 2, \dots, n$, $\Delta x_i(mk-l) = x_i(mk-l) - x_i(mk-l^-)$, and $x_i(mk-l^-) = \lim_{h \rightarrow 0^-} x_i(mk-l+h)$. Moreover, n denotes the number of neurons in the network, $x_i(t)$ corresponds to the state of the i th unit at time t , $f_j(x_j(t))$ and $g_j(x_j(m[(t+l)/m]))$ denote, respectively, the measures of activation to its incoming potentials of the unit j at time t and discrete-time $m[(t+l)/m]$, a_i denotes the rate with which the unit i resets its potential to the resting state when isolated from other units and inputs, b_{ij} denotes the synaptic connection weight of the unit j on the unit i at time t , c_{ij} denotes the synaptic connection weight of the unit j on the unit i at discrete-time $m[(t+l)/m]$, and d_i is the input from outside the network to the unit i . The numbers $x_i(mk-l^-)$ and $x_i(mk-l)$ are, respectively, the states of the i th unit before and after impulse perturbation at the moment $mk-l$, $k \in \mathbb{N}$, and represent the abrupt change of the state $J_{ik}(x_i(mk-l^-))$ at the impulsive moment $mk-l$.

Let us clarify why the IDEPCA (4a)-(4b) is of alternately advanced and retarded type; that is, the argument can change its deviation character during the motion. The argument is deviated if it is advanced or retarded. Fix $k \in \mathbb{N}$, and consider the IDEPCA on the interval $I_k = [mk -$

$l, m(k+1) - l$). Then, the identification function $m[(t+l)/m]$ is equal to mk . If $t \in I_k^+ = [mk - l, mk)$, then $m[(t+l)/m] \geq t$ and IDEPCA (4a)-(4b) is an equation with advanced argument. Similarly, if $t \in I_k^- = (mk, m(k+1) - l)$ then $m[(t+l)/m] < t$ and IDEPCA (4a)-(4b) is an equation with retarded argument. Consequently, IDEPCA (4a)-(4b) changes the type of deviation of the argument during the process. In other words, the IDEPCA (4a)-(4b) is of alternately advanced and retarded type.

For any solution $x(t) = (x_1(t), \dots, x_n(t))^T$ of IDEPCA (4a)-(4b), the model can be summarized as follows:

$$\frac{dx(t)}{dt} = -Ax(t) + Bf(x(t)) + Cg\left(x\left(m\left[\frac{t+l}{m}\right]\right)\right) + D, \quad t \neq mk - l, \quad (5a)$$

$$\Delta x|_{t=mk-l} = J_k(x(mk-l^-)), \quad k \in \mathbb{N}, \quad (5b)$$

where $A = \text{diag}(a_1, \dots, a_n)$, $B = (b_{ij})_{n \times n}$, and $C = (c_{ij})_{n \times n}$ are constant matrices and $D = (d_1, \dots, d_n)$ is a constant vector. Moreover, the functions $f: \mathbb{R}^n \mapsto \mathbb{R}^n$, $g: \mathbb{R}^n \mapsto \mathbb{R}^n$ satisfy $(\partial f_i / \partial x_j) = (\partial g_i / \partial x_j) = 0$ when $i \neq j$.

To the best of our knowledge, cellular neural network with piecewise constant argument has been developed by few authors, for example, Huang et al. Reference [41] considered first the following cellular neural network with piecewise constant delay:

$$\frac{dx_i(t)}{dt} = -a_i([t])x_i(t) + \sum_{j=1}^n \{c_{ij}([t])g_j(x_j([t]))\} + d_i([t]), \quad (6)$$

where $[\cdot]$ signifies the greatest integer function. Some sufficient conditions of existence and attractivity of almost periodic sequence solution were given for the corresponding discrete-time analogue:

$$x_i(k+1) = x_i(k)e^{-a_i(k)} + \frac{1 - e^{-a_i(k)}}{a_i(k)} \times \left\{ \sum_{j=1}^n c_{ij}(k)g_j(x_j(k)) + d_i(k) \right\}. \quad (7)$$

In 2010, Akhmet and Yilmaz [8] considered first the following impulsive neural network with only piecewise constant retarded argument:

$$\begin{aligned} \frac{dx_i(t)}{dt} &= -a_i x_i(t) + \sum_{j=1}^m \{b_{ij} f_j(x_j(t)) + c_{ij} g_j(x_j(\beta(t)))\} \\ &\quad + d_i, \quad t \neq \theta_k, \\ \Delta x_i|_{t=\theta_k} &= I_k(x_i(\theta_k^-)), \quad i = 1, 2, \dots, m, \quad k \in \mathbb{N}, \end{aligned} \quad (8)$$

where $\beta(t) = \theta_k$ if $\theta_k < t < \theta_{k+1}$, $k \in \mathbb{N}$, $t \in \mathbb{R}^+$, is an identification function and $\theta_k > 0$, $k \in \mathbb{N}$, is a sequence

of real numbers. Several sufficient conditions are obtained for the existence and stability of a unique ω -periodic solution.

In this paper, we for the first time study the dynamic behavior of impulsive cellular neural network models that combine the properties of impulsive differential equations and discrete-time difference equations, that is, the following impulsive cellular neural network with piecewise alternately advanced and retarded argument:

$$\begin{aligned} \frac{dx_i(t)}{dt} &= -a_i x_i(t) \\ &\quad + \sum_{j=1}^n \left\{ b_{ij} f_j(x_j(t)) + c_{ij} g_j\left(x_j\left(m\left[\frac{t+l}{m}\right]\right)\right) \right\} \\ &\quad + d_i, \quad t \neq mk - l, \\ \Delta x_i|_{t=mk-l} &= J_{ik}(x_i(mk-l^-)), \quad i = 1, 2, \dots, n, \quad k \in \mathbb{N}. \end{aligned} \quad (9)$$

The purpose of this paper is to derive some new and simple sufficient conditions for the existence and uniqueness of solutions of the ICNNs with IDEPCA system (5a)-(5b), which is globally exponentially stable. This paper is organized as follows. In Section 2, we establish several criteria for the existence and uniqueness of a unique equilibrium of the ICNNs with IDEPCA system and the equivalence lemma for (5a)-(5b). Here, a new IDEPCA Gronwall-type inequality is very useful. In Section 3, we derive some sufficient conditions which ensure that a unique equilibrium of the ICNNs with IDEPCA system (5a)-(5b) is globally exponentially stable. In Section 4, two illustrative examples and the numerical simulations are given to demonstrate the effectiveness of our results. The conclusions are drawn in Section 5.

2. Existence and Uniqueness Theorems

In this section, sufficient conditions that govern the network parameters and the activation functions are established for the existence of a unique equilibrium state of the impulsive cellular neural network models (5a)-(5b).

2.1. Preliminaries and Definition. In this section, we will focus our attention on some preliminary results which will be used in the existence and uniqueness of solutions of the ICNNs with IDEPCA system (5a)-(5b).

For every $t \in \mathbb{R}$, let $i = i(t) \in \mathbb{N}$ be the unique integer such that $t \in I_i = [mi - l, m(i+1) - l)$.

For the sake of convenience, two of the standing assumptions are formulated below.

Lipschitz Condition

(L) The activation functions f_j and g_j with $f_j(0) = 0$, $g_j(0) = 0$ ($j = 1, 2, \dots, n$) satisfy the Lipschitz

condition; that is, there are constants $\mathcal{L}_j^f, \mathcal{L}_j^g > 0$ such that

$$|f_j(u) - f_j(v)| \leq \mathcal{L}_j^f |u - v|, \quad (10)$$

$$|g_j(u) - g_j(v)| \leq \mathcal{L}_j^g |u - v|$$

for all $u, v \in \mathbb{R}^+$.

The impulsive operator J_k satisfies

$$|J_{jk}(u) - J_{jk}(v)| \leq \mathcal{L}_k^J |u - v|, \quad (11)$$

for all $u, v \in \mathbb{R}^+$, $j = 1, \dots, n$, $k \in \mathbb{N}$, where $\mathcal{L}_k^J$ is a positive Lipschitz constant.

Existence condition

(E) Consider

$$\max_{i \in [1, \dots, n]} \left\{ \frac{1 - e^{-l a_*}}{a_*} \left(\sum_{j=1}^n [\mathcal{L}_j^f |b_{ij}| + \mathcal{L}_j^g |c_{ij}|] \right) \right\} < 1, \quad (12)$$

where $\min_{i \in [1, \dots, n]} a_i = a_*$.

First, we prove the existence and uniqueness of solutions of IDEPCA system (5a)-(5b). A natural extension of the original definition of a solution of DEPCA [28–30, 42] allows us to define a solution of IDEPCA system.

Definition 1. A function x is a solution of IDEPCA system (5a)-(5b) in $\mathbb{R}^+ = [0, \infty)$ if

- (i) $x(t)$ is continuous for $t \in \mathbb{R}^+$ with the possible exception of the points $t = mk - l$, $k \in \mathbb{N}$,
- (ii) $x(t)$ is right continuous and has left-hand limits at the points $t = mk - l$, $k \in \mathbb{N}$,
- (iii) $x(t)$ is differentiable and satisfies (5a) for any $t \in \mathbb{R}^+$, with the possible exception of the points $t = mk - l$, $k \in \mathbb{N}$, where one-sided derivatives exist,
- (iv) $x(n)$ satisfies (5b) for $n = km - l$, $k \in \mathbb{N}$.

To study nonlinear IDEPCA system, we will use the approach based on the construction of an equivalent integral equation. Let us give the following proposition.

Proposition 2. Let $(\tau, x_0) \in \mathbb{R}^+ \times \mathbb{R}^n$. The function $x(t) = x(t, \tau, x_0)$ is a solution on $\mathbb{R}^+$ of the IDEPCA system (5a)-(5b) in the sense of Definition 1 if and only if it is a solution of the integral equation

$$\begin{aligned} x(t) &= e^{-A(t-\tau)} x_0 \\ &+ \int_{\tau}^t e^{-A(t-s)} \left[Bf(x(s)) \right. \\ &\quad \left. + Cg \left(x \left(m \left[\frac{s+l}{m} \right] \right) \right) + D \right] ds \\ &+ \sum_{k=i(\tau)+1}^{i(t)} e^{-A(t-(mk-l))} J_k(x(mk-l^-)), \quad t \in \mathbb{R}^+. \end{aligned} \quad (13)$$

In particular, one has the following integral equations: for $i = 1, \dots, n$, $t \in \mathbb{R}^+$,

$$\begin{aligned} x_i(t) &= e^{-a_i(t-\tau)} x_i(\tau) \\ &+ \int_{\tau}^t e^{-a_i(t-s)} \left[\sum_{j=1}^n b_{ij} f_j(x_j(s)) \right. \\ &\quad \left. + \sum_{j=1}^n c_{ij} g_j \left(x_j \left(m \left[\frac{s+l}{m} \right] \right) \right) + d_i \right] ds \\ &+ \sum_{k=i(\tau)+1}^{i(t)} e^{-a_i(t-(mk-l))} J_{ik}(x_i(mk-l^-)). \end{aligned} \quad (14)$$

The proof of Proposition 2 is almost identical to the verification in [7] with slight changes which are caused by the piecewise constant argument.

In the next, we give the following lemma about IDEPCA integral inequality of Gronwall type, which is one of the most important auxiliary results of the present paper.

Lemma 3. Let $u : \mathbb{R} \rightarrow [0, \infty)$ be a function such that u is continuous with possible points of discontinuity of the first kind at $t = mk - l$, $k \in \mathbb{N}$, and η_1, η_2 are nonnegative real constants satisfying

$$v := (\eta_1 + \eta_2)l < 1. \quad (15)$$

Suppose that for $t \geq \tau$ the inequality

$$\begin{aligned} u(t) &\leq u(\tau) + \int_{\tau}^t \left(\eta_1 u(s) + \eta_2 u \left(m \left[\frac{s+l}{m} \right] \right) \right) ds \\ &+ \sum_{k=i(\tau)+1}^{i(t)} \beta_k u(mk-l^-) \end{aligned} \quad (16)$$

holds. Then for $t \geq \tau$,

$$u(t) \leq u(\tau) \prod_{k=i(\tau)+1}^{i(t)} (1 + \beta_k) \exp \left\{ \left(\eta_1 + \frac{\eta_2}{1-v} \right) (t - \tau) \right\}, \quad (17)$$

$$\begin{aligned} u \left(m \left[\frac{t+l}{m} \right] \right) &\leq \frac{u(\tau)}{1-v} \prod_{k=i(\tau)+1}^{i(t)} (1 + \beta_k) \\ &\times \exp \left\{ \left(\eta_1 + \frac{\eta_2}{1-v} \right) (t - \tau) \right\}, \end{aligned} \quad (18)$$

$$u(mi) \leq (1-v)^{-1} u(mi-l), \quad i \in \mathbb{N}. \quad (19)$$

Proof. Call $v(t)$ the right member of (16). So $v(\tau) = u(\tau)$, $u \leq v$, and v is a piecewise differentiable and nondecreasing function and, by (16), it satisfies

$$\begin{aligned} v'(t) &\leq \eta_1 v(t) + \eta_2 v \left(m \left[\frac{t+l}{m} \right] \right), \\ v(mk-l) &\leq (1 + \beta_k) v(mk-l^-), \end{aligned} \quad (20)$$

$k \in \mathbb{N}$ and for any $t \geq r$ with $t, r \in I_i$

$$v(t) - v(r) \leq \int_r^t \left(\eta_1 v(s) + \eta_2 v \left(m \left\lfloor \frac{s+l}{m} \right\rfloor \right) \right) ds. \quad (21)$$

With $t = mi$ and $r = mi - l$ in (21) for $t \in I_i$, since v is a nondecreasing function, we get

$$\begin{aligned} v(mi) &\leq v(mi - l) + \int_{mi-l}^{mi} (\eta_1 v(s) + \eta_2 v(mi)) ds \\ &\leq v(mi - l) + (\eta_1 + \eta_2) l \cdot v(mi). \end{aligned} \quad (22)$$

Considering the particular case $\tau = t_i$ and taking $v(t_i) = u(t_i)$ and $u \leq v$, by (15) and (22), estimate (19) follows. Take now in (21) $t \in I_i$ and $r = mi - l$ to obtain

$$\begin{aligned} v(t) &\leq v(mi - l) + \int_{mi-l}^t (\eta_1 v(s) + \eta_2 v(mi)) ds \\ &\leq v(mi - l) + \int_{mi-l}^t \left(\eta_1 v(s) + \frac{\eta_2}{1-v} v(mi - l) \right) ds \\ &\leq v(mi - l) + \int_{mi-l}^t \left(\eta_1 + \frac{\eta_2}{1-v} \right) v(s) ds \end{aligned} \quad (23)$$

because v is a nondecreasing function. Now, we can apply the classical Gronwall's Lemma to get

$$v(t) \leq v(mi - l) \exp \left\{ \left(\eta_1 + \frac{\eta_2}{1-v} \right) (t - (mi - l)) \right\} \quad (24)$$

for $t \in I_i$.

By the impulsive effect (20), we have

$$\begin{aligned} v(m(i+1) - l) &\leq (1 + \beta_{i+1}) v(mi - l) \\ &\quad \times \exp \left\{ m \cdot \left(\eta_1 + \frac{\eta_2}{1-v} \right) \right\}. \end{aligned} \quad (25)$$

From (25), recursively we obtain

$$\begin{aligned} u(t) &\leq v(t) \leq v(\tau) \prod_{k=i(\tau)+1}^{i(t)} (1 + \beta_k) \\ &\quad \times \exp \left\{ \left(\eta_1 + \frac{\eta_2}{1-v} \right) (t - \tau) \right\}, \end{aligned} \quad (26)$$

using $v(\tau) = u(\tau)$ and (19); then we give (17) and (18). The proof is complete. This IDEPCA inequality of Gronwall type seems to be new. $\square$

We need to have the global unique existence of solutions $x(t) = x(t, \tau, x_0)$ on $\mathbb{R}^+$ of the nonlinear IDEPCA system (5a)-(5b).

One can easily see that IDEPCA system (5a)-(5b) has the form of DEPCA system without impulsive effect within the intervals $[mi - l, m(i+1) - l]$, $i \in \mathbb{N}$; then using the same technique of [34, 35, 37] we have the following results.

Proposition 4. Suppose that conditions (L) and (E) hold. For any $(\tau, x_0) \in \mathbb{R}^+ \times \mathbb{R}^n$ there exists a unique solution $x(t) = x(t, \tau, x_0)$ of the IDEPCA system (5a)-(5b) on $[mi(\tau) - l, m(i(\tau) + 1) - l]$.

Theorem 5. Under conditions (L) and (E), for every $(\tau, x_0) \in \mathbb{R}^+ \times \mathbb{R}^n$, there exists a unique solution $x(t) = x(t, \tau, x_0)$ of the IDEPCA system (5a)-(5b) with $x(\tau) = x_0$ for $t \in [\tau, \infty)$ in the sense of Definition 1.

Proof. Fix $\tau \in \mathbb{R}^+$; then $\tau \in I_{i(\tau)} = [mi(\tau) - l, mi(\tau) + m - l]$. Use Proposition 4 with $x(\tau) = x_0$ to obtain the unique solution $x(t) = x(t, \tau, x_0)$ on $I_{i(\tau)}$. Then apply the impulse condition to evaluate uniquely

$$\begin{aligned} &x(mi(\tau) + m - l, \tau, x_0) \\ &= x(mi(\tau) + m - l^-, \tau, x_0) \\ &\quad + J_{i(\tau)+1}(x(mi(\tau) + m - l^-, \tau, x_0)). \end{aligned} \quad (27)$$

Next, on the interval $I_{i(\tau)+1} = [mi(\tau) + m - l, mi(\tau) + 2m - l]$ the solution satisfies the DEPCA:

$$\begin{aligned} \frac{dy_i(t)}{dt} &= -a_i y_i(t) \\ &\quad + \sum_{j=1}^n \left\{ b_{ij} f_j(y_j(t)) + c_{ij} g_j \left(y_j \left(m \left\lfloor \frac{t+l}{m} \right\rfloor \right) \right) \right\} \\ &\quad + d_i, \quad i = 1, 2, \dots, n. \end{aligned} \quad (28)$$

The IDEPCA system has a unique solution $y(t, mi(\tau) + m - l, x(mi(\tau) + m - l, \tau, x_0))$. By definition of the solution of IDEPCA system (5a)-(5b), $x(t, \tau, x_0) = y(t, mi(\tau) + m - l, x(mi(\tau) + m - l, \tau, x_0))$ on $I_{i(\tau)+1} = [mi(\tau) + m - l, mi(\tau) + 2m - l]$. The mathematical induction completes the proof. $\square$

2.2. Existence and Uniqueness of Equilibrium. When impulsive cellular neural network models are used for the solution of optimization problems, one of the fundamental issues in the design of a network is concerned with the existence of a unique globally exponentially stable equilibrium state of network (5a)-(5b). Without requiring the boundedness, differentiability, or monotonicity, we establish easily verifiable sufficient conditions for the existence of a unique equilibrium state in this section.

Let us denote an equilibrium state of the impulsive cellular neural network models (5a)-(5b) by the constant vector $x^* = (x_1^*, x_2^*, \dots, x_n^*)^T \in \mathbb{R}^n$, where each x_i^* is governed by the algebraic system

$$\begin{aligned} 0 &= -a_i x_i^* + \sum_{j=1}^n \left\{ b_{ij} f_j(x_j^*) + c_{ij} g_j(x_j^*) \right\} \\ &\quad + d_i, \quad i = 1, \dots, n. \end{aligned} \quad (29)$$

Here, it is assumed that the impulse functions $J_{ik}(\cdot)$ satisfy $J_{ik}(x_i^*) = 0$ for all $i = 1, \dots, n, k \in \mathbb{N}$.

In the following theorem, we obtain sufficient conditions for the existence of a unique equilibrium, $x^* = (x_1^*, x_2^*, \dots, x_n^*)^T \in \mathbb{R}^n$, of the impulsive cellular neural network models (5a)-(5b).

Theorem 6. Suppose that conditions (L) and (E) hold and the neural parameters a_i , b_{ij} , and c_{ij} and Lipschitz constants $\mathcal{L}_i^f$, $\mathcal{L}_i^g$ satisfy

$$a_i > \mathcal{L}_i^f \sum_{j=1}^n |b_{ij}| + \mathcal{L}_i^g \sum_{j=1}^n |c_{ij}|, \quad i, j = 1, \dots, n. \quad (30)$$

Then there exists a unique equilibrium state x^* of the ICNNs with IDEPCA system (5a)-(5b).

Proof. Let us consider a mapping $G(u) = (G_1(u), G_2(u), \dots, G_n(u))^T \in \mathbb{R}^n$, where $u = (u_1, u_2, \dots, u_n)^T \in \mathbb{R}^n$ and

$$G_i(u) = \frac{1}{a_i} \left[\sum_{j=1}^n \{b_{ij} f_j(u_j) + c_{ij} g_j(u_j)\} + d_i \right], \quad (31)$$

$$i = 1, \dots, n.$$

By applying the hypotheses,

$$\begin{aligned} & \max_{1 \leq i \leq n} |G_i(u) - G_i(v)| \\ &= \max_{1 \leq i \leq n} \left| \frac{1}{a_i} \left[\sum_{j=1}^n \{b_{ij} f_j(u_j) + c_{ij} g_j(u_j)\} + d_i \right] - \frac{1}{a_i} \left[\sum_{j=1}^n \{b_{ij} f_j(v_j) + c_{ij} g_j(v_j)\} + d_i \right] \right| \\ &\leq \max_{1 \leq i \leq n} \left\{ \frac{1}{a_i} \sum_{j=1}^n \{|b_{ij}| |f_j(u_j) - f_j(v_j)|\} + \frac{1}{a_i} \sum_{j=1}^n \{|c_{ij}| |g_j(u_j) - g_j(v_j)|\} \right\} \\ &\leq \max_{1 \leq i \leq n} \left\{ \frac{1}{a_i} \sum_{j=1}^n \{\mathcal{L}_j^f |b_{ij}| |u_j - v_j|\} + \frac{1}{a_i} \sum_{j=1}^n \{\mathcal{L}_j^g |c_{ij}| |u_j - v_j|\} \right\} \\ &\leq \max_{1 \leq i \leq n} \left\{ \frac{1}{a_i} \sum_{j=1}^n \{\mathcal{L}_j^f |b_{ij}| + \mathcal{L}_j^g |c_{ij}|\} \right\} \cdot \max_{1 \leq j \leq n} |u_j - v_j|, \end{aligned} \quad (32)$$

where the number

$$\rho = \frac{1}{a_i} \sum_{j=1}^n \{\mathcal{L}_j^f |b_{ij}| + \mathcal{L}_j^g |c_{ij}|\} \quad (33)$$

satisfies $0 < \rho < 1$ by virtue of condition (30). Thus,

$$\max_{1 \leq i \leq n} |G_i(u) - G_i(v)| \leq \rho \max_{1 \leq j \leq n} |u_j - v_j| \quad (34)$$

for any two vectors $u, v \in \mathbb{R}^n$ implying that the mapping $G : \mathbb{R}^n \rightarrow \mathbb{R}^n$ is a global contraction on $\mathbb{R}^n$ endowed with the supremum norm. Hence, there is a unique fixed point $x^* \in \mathbb{R}^n$ that satisfies $G(x^*) = x^*$ (i.e., $G_i(x^*) = x_i^*$ for $i = 1, \dots, n$). This point defines the unique equilibrium state of the impulsive cellular neural network models (5a)-(5b). The proof is now complete. $\square$

3. Global Exponential Stability of Equilibrium

The existence and stability of a unique equilibrium state are usually a requirement in the design of cellular neural network models for various applications, particularly when there are destabilizing agents such as retarded arguments and impulses. However, even if the unique stable state exists, these agents may affect the convergence speed of the network, which in turn can downgrade the performance of the network in applications that demand fast computation in real-time mode. Thus, exponential stability is usually desirable for an impulsive network, and sufficient conditions for the global exponential stability of the unique equilibrium state x^* of the ICNNs with IDEPCA system (5a)-(5b) are obtained in this section.

For analytical convenience, the ICNNs with IDEPCA system (5a)-(5b) can be simplified as follows. Let

$$\begin{aligned} z_i(t) &= x_i(t) - x_i^*, \quad \hat{f}(z_i(t)) = f(x_i(t) + x_i^*) - f(x_i^*), \\ \hat{g}\left(z_i\left(m\left[\frac{t+l}{m}\right]\right)\right) &= g\left(x_i\left(m\left[\frac{t+l}{m}\right]\right) + x_i^*\right) - g(x_i^*), \\ \hat{J}_{ik}(z_i(mk-l)) &= J_{ik}(x_i(mk-l) + x_i^*), \end{aligned} \quad (35)$$

so that the ICNNs with IDEPCA system (5a)-(5b) can be written as

$$\begin{aligned} \frac{dz(t)}{dt} &= -Az(t) + B\hat{f}(z(t)) \\ &\quad + C\hat{g}\left(z\left(m\left[\frac{t+l}{m}\right]\right)\right), \quad t \neq mk-l, \end{aligned} \quad (36)$$

$$\Delta x|_{t=mk-l} = \hat{J}_k(z(mk-l)), \quad k \in \mathbb{N},$$

where $\hat{f}(z(t)) = [\hat{f}_1(z_1(t)), \dots, \hat{f}_n(z_n(t))]^T$, $\hat{g}(z(m[(t+l)/m])) = [\hat{g}_1(z_1(m[(t+l)/m])), \dots, \hat{g}_n(z_n(m[(t+l)/m]))]^T$ and $\hat{J}_k(z(mk-l)) = [J_{1k}(x_1(mk-l) + x_1^*), \dots, J_{nk}(x_n(mk-l) + x_n^*)]^T$.

The activation functions $\hat{f}_i(\cdot)$, inheriting the properties of $f_i(\cdot)$, satisfy

$$\hat{f}_i(0) = 0, \quad |\hat{f}_i(u) - \hat{f}_i(v)| \leq \mathcal{L}_i^f |u - v|, \quad (37)$$

the functions $\hat{g}_i(\cdot)$ inherit the properties of $g_i(\cdot)$, namely,

$$\hat{g}_i(0) = 0, \quad |\hat{g}_i(u) - \hat{g}_i(v)| \leq \mathcal{L}_i^g |u - v|, \quad (38)$$

and the impulsive operator $\hat{J}_k$ satisfies

$$\hat{J}_k(0) = 0, \quad \left| \hat{J}_k(u) - \hat{J}_k(v) \right| \leq \mathcal{L}_k^J |u_i - v_i|, \quad (39)$$

for all $u, v \in \mathbb{R}^+$, $i = 1, \dots, n$, $k \in \mathbb{N}$.

It is clear that the stability of the zero solution of (36) is equivalent to that of the equilibrium x^* of the ICNNs with IDEPCA system (4a)-(4b). Therefore, we restrict our discussion to the stability of the zero solution of (36).

First of all, we give the following definition and lemma, which will be used in the proof of the stability of the zero solution for the ICNNs with IDEPCA system.

Definition 7. The equilibrium x^* of the ICNNs with IDEPCA system (5a)-(5b) is said to be globally exponentially stable if there exist positive constants α and λ such that the estimation

$$|x(t) - x^*| \leq \alpha |x(\tau) - x^*| e^{-\lambda(t-\tau)} \quad (40)$$

is valid for all $t \geq \tau$.

Lemma 8. If (L) and (E) are satisfied, then the solutions φ and ψ of the IDEPCA system (5a)-(5b) satisfy for all $t \geq \tau$ the inequality

$$|\varphi(t) - \psi(t)| \leq |\varphi(\tau) - \psi(\tau)| \exp(-\lambda_{i(t)} \cdot (t - \tau)), \quad (41)$$

where $\lambda_{i(t)} = a_* - \beta^* - \mathcal{L}_{i(t)}$, $a_* = \min_{i \in [1, \dots, n]} a_i$, $\mathcal{L}_{i(t)} = \max_{i(\tau)+1 \leq k \leq i(t)} (\ln(1 + \mathcal{L}_k^J)/m)$,

$$\begin{aligned} \beta^* &= \max_{i \in [1, \dots, n]} \beta_i \\ &= \max_{i \in [1, \dots, n]} \sum_{j=1}^n (\mathcal{L}_j^f |b_{ij}| + \mathcal{L}_j^g |c_{ij}| (1 - \tilde{\nu})^{-1} \\ &\quad \times \exp(a_* \cdot (m - l))), \\ \tilde{\nu} &= \max_{i \in [1, \dots, n]} \left(\sum_{j=1}^n \mathcal{L}_j^f |b_{ij}| + \mathcal{L}_j^g |c_{ij}| \exp(a_* \cdot (m - l)) \right) \\ &\quad \cdot l < 1. \end{aligned} \quad (42)$$

Proof. Suppose that $\varphi(t) = (\varphi_1, \dots, \varphi_n)^T$ and $\psi(t) = (\psi_1, \dots, \psi_n)^T$ are arbitrary solutions of the IDEPCA system (5a)-(5b). Let $y(t) = \varphi(t) - \psi(t)$ and by (5a) and (5b) it follows that $y(\cdot)$ satisfies

$$\begin{aligned} \dot{y}(t) &= -Ay(t) + B(f(y(t) + \psi(t)) - f(\psi(t))) \\ &\quad + C \left\{ g \left(y \left(m \left[\frac{t+l}{m} \right] \right) + \psi \left(m \left[\frac{t+l}{m} \right] \right) \right) \right. \\ &\quad \left. - g \left(\psi \left(m \left[\frac{t+l}{m} \right] \right) \right) \right\}, \\ \Delta y|_{t=mk-l} &= J_k(y(mk-l^-) + \psi(mk-l^-)) \\ &\quad - J_k(\psi(mk-l^-)), \quad k \in \mathbb{N}. \end{aligned} \quad (43)$$

By the variation of parameters formula, it can be proved that

$$\begin{aligned} y(t) &= e^{-A(t-\tau)} y(\tau) + \int_{\tau}^t e^{-A(t-s)} \mathcal{R}(s, y(s)) ds \\ &\quad + \sum_{k=i(\tau)+1}^{i(t)} e^{-A(t-(mk-l))} \mathcal{J}_k(y(mk-l^-)), \end{aligned} \quad (44)$$

where

$$\begin{aligned} \mathcal{R}(s, y(s)) &:= B \\ &\quad \cdot \{f(y(s) + \psi(s)) - f(\psi(s))\} \\ &\quad + C \cdot \left\{ g \left(y \left(m \left[\frac{s+l}{m} \right] \right) \right. \right. \\ &\quad \left. \left. + \psi \left(m \left[\frac{s+l}{m} \right] \right) \right) \right. \\ &\quad \left. - g \left(\psi \left(m \left[\frac{s+l}{m} \right] \right) \right) \right\}, \end{aligned} \quad (45)$$

$$\begin{aligned} \mathcal{J}_k(y(mk-l^-)) &:= J_k(y(mk-l^-) + \psi(mk-l^-)) \\ &\quad - J_k(\psi(mk-l^-)). \end{aligned}$$

Notice that (L) implies that

$$\begin{aligned} |\mathcal{R}_i(s, y(s))| &\leq \left(\sum_{j=1}^n \mathcal{L}_j^f |b_{ij}| |y_i(s)| \right. \\ &\quad \left. + \sum_{j=1}^n \mathcal{L}_j^g |c_{ij}| \left| y_i \left(m \left[\frac{s+l}{m} \right] \right) \right| \right), \\ |\mathcal{R}_i(s, y(s))| &\leq \max_{i \in [1, \dots, n]} \left(\sum_{j=1}^n \mathcal{L}_j^f |b_{ij}| |y(s)| \right. \\ &\quad \left. + \sum_{j=1}^n \mathcal{L}_j^g |c_{ij}| \left| y \left(m \left[\frac{s+l}{m} \right] \right) \right| \right), \\ |\mathcal{J}_k(y(mk-l^-))| &\leq \mathcal{L}_k^J |y(mk-l^-)|. \end{aligned} \quad (46)$$

By (44), we can deduce that $v_i(t) = \exp(a_* \cdot (t - \tau)) |y_i(t)|$ satisfies

$$\begin{aligned} |v_i(t)| &\leq |\varphi_i(\tau) - \psi_i(\tau)| \\ &\quad + \int_{\tau}^t \left[\sum_{j=1}^n \mathcal{L}_j^f |b_{ij}| |v_j(s)| \right. \\ &\quad \left. + \sum_{j=1}^n \mathcal{L}_j^g |c_{ij}| \left| v_j \left(m \left[\frac{s+l}{m} \right] \right) \right| \right] ds \end{aligned}$$

$$\begin{aligned} & \times \exp \left(a_* \cdot \left(s - m \left\lfloor \frac{s+l}{m} \right\rfloor \right) \right) \Big] ds \\ & + \sum_{k=i(\tau)+1}^{i(t)} \mathcal{L}_k^J |v_i(mk-l^-)|, \end{aligned} \quad (47)$$

or

$$\begin{aligned} |v(t)| & \leq |\varphi(\tau) - \psi(\tau)| \\ & + \max_{i \in [1, \dots, n]} \int_{\tau}^t \left[\sum_{j=1}^n \mathcal{L}_j^f |b_{ij}| |v(s)| \right. \\ & \quad \left. + \sum_{j=1}^n \mathcal{L}_j^g |c_{ij}| \left| v \left(m \left\lfloor \frac{s+l}{m} \right\rfloor \right) \right| \right] \\ & \quad \times \exp \left(a_* \cdot \left(s - m \left\lfloor \frac{s+l}{m} \right\rfloor \right) \right) \Big] ds \\ & + \sum_{k=i(\tau)+1}^{i(t)} \mathcal{L}_k^J |v(mk-l^-)| \\ & \leq |\varphi(\tau) - \psi(\tau)| + \max_{i \in [1, \dots, n]} \\ & \quad \times \int_{\tau}^t \left[\sum_{j=1}^n \mathcal{L}_j^f |b_{ij}| |v(s)| + \sum_{j=1}^n \mathcal{L}_j^g |c_{ij}| \right. \\ & \quad \left. \times \exp \left(a_* \cdot (m-l) \right) \left| v \left(m \left\lfloor \frac{s+l}{m} \right\rfloor \right) \right| \right] ds \\ & + \sum_{k=i(\tau)+1}^{i(t)} \mathcal{L}_k^J |v(mk-l^-)|, \end{aligned} \quad (48)$$

for any finite $t \in [\tau, \infty)$.

Hence, by Lemma 3 of IDEPCA Gronwall's inequality implies

$$\begin{aligned} |v(t)| & \leq |\varphi(\tau) - \psi(\tau)| \prod_{k=i(\tau)+1}^{i(t)} (1 + \mathcal{L}_k^J) \\ & \times \exp \left(\max_{i \in [1, \dots, n]} \left\{ \sum_{j=1}^n \mathcal{L}_j^f |b_{ij}| + \frac{1}{1-\tilde{v}} \sum_{j=1}^n \mathcal{L}_j^g |c_{ij}| \right. \right. \\ & \quad \left. \left. \times \exp(a_* \cdot (m-l)) \right\} (t-\tau) \right). \end{aligned} \quad (49)$$

Then, we have

$$|\varphi(t) - \psi(t)| \leq |\varphi(\tau) - \psi(\tau)| \prod_{k=i(\tau)+1}^{i(t)} (1 + \mathcal{L}_k^J) \quad (50)$$

$$\times \exp \left\{ - \left(a_* - \max_{i \in [1, \dots, n]} \beta_i \right) (t-\tau) \right\},$$

or

$$\begin{aligned} |\varphi(t) - \psi(t)| & \leq |\varphi(\tau) - \psi(\tau)| \\ & \times \exp \left\{ - \left(a_* - \max_{i \in [1, \dots, n]} \beta_i \right. \right. \\ & \quad \left. \left. - \max_{i(\tau)+1 \leq k \leq i(t)} \frac{\ln(1 + \mathcal{L}_k^J)}{m} \right) (t-\tau) \right\}, \end{aligned} \quad (51)$$

and the statement (41) follows. $\square$

The following result will show sufficient conditions for the global exponential stability of the unique equilibrium of the ICNNs with IDEPCA system (5a)-(5b).

Theorem 9. *If the assumptions of Theorem 6, (42) and*

$$a_* - \beta^* - \mathcal{L}_{i(t)} > 0, \quad t \in \mathbb{R}^+, \quad (52)$$

are satisfied, then the unique equilibrium x^ of the ICNNs with IDEPCA system (5a)-(5b) is globally exponentially stable.*

Proof. By Theorem 6, we know that the IDEPCA system (5a)-(5b) has a unique equilibrium x^* . Let $x(t, x_0)$ be an arbitrary solution of (5a)-(5b) with initial condition x_0 and define $z(t) = x(t, x_0) - x^*$. By Lemma 8 and (42), we obtain

$$|z(t)| \leq |z(\tau)| \exp(-\lambda_{i(t)} \cdot (t-\tau)), \quad (53)$$

where $\lambda_{i(t)} = a_* - \beta^* - \mathcal{L}_{i(t)}$. So, using (52), we see that $|z(t)| \rightarrow 0$ as $t \rightarrow \infty$. That is, the zero solution of ICNNs with IDEPCA system (36) is globally exponentially stable. Therefore, the unique equilibrium x^* of the ICNNs with IDEPCA system (5a)-(5b) is globally exponentially stable. $\square$

Remark 10. To the best of the author's knowledge, this is the first time we investigate impulsive cellular neural network models with piecewise alternately advanced and retarded argument in equilibrium case. Sufficient conditions are gained for the existence and exponential stability of a unique equilibrium of the ICNNs with IDEPCA system. And our results can be extended to a unique equilibrium of the CNNs with DEPCA system. See Corollaries 11–12. Our results about exponential stability of a unique equilibrium of the ICNNs with IDEPCA system may give some insight into the application of neural networks.

As immediate corollaries of Lemma 8 and Theorem 9, the following results without impulsive effects are true.

Corollary 11. If (L) and (E) are satisfied, then the solutions φ and ψ of the DEPCA system (5a) satisfy for all $t \geq \tau$ the inequality

$$|\varphi(t) - \psi(t)| \leq |\varphi(\tau) - \psi(\tau)| \exp(-\lambda \cdot (t - \tau)), \quad (54)$$

where $\lambda = a_* - \beta^*$, $a_* = \min_{i \in [1, \dots, n]} a_i$,

$$\begin{aligned} \beta^* &= \max_{i \in [1, \dots, n]} \beta_i = \max_{i \in [1, \dots, n]} \sum_{j=1}^n (\mathcal{L}_j^f |b_{ij}| + \mathcal{L}_j^g |c_{ij}| (1 - \tilde{\nu})^{-1} \\ &\quad \times \exp(a_* \cdot (m - l))), \\ \tilde{\nu} &= \max_{i \in [1, \dots, n]} \left(\sum_{j=1}^n \mathcal{L}_j^f |b_{ij}| \right. \\ &\quad \left. + \mathcal{L}_j^g |c_{ij}| \exp(a_* \cdot (m - l)) \right) \cdot l < 1. \end{aligned} \quad (55)$$

Corollary 12. If the assumptions of Corollary 11 and

$$a_* - \beta^* > 0 \quad (56)$$

are satisfied, then the unique equilibrium x^* of the CNNs with DEPCA system (5a) is globally exponentially stable.

Remark 13. In [41], authors investigated discrete-time cellular neural network without impulsive effects in almost periodic case. Simple sufficient conditions are gained for a unique almost periodic sequence solution which is globally attractive. When $m = 1$, $l = 0$, this conclusion of Corollary 12 cannot be derived by applying the corresponding stability result for cellular neural networks given in the literature [41] with a_i , b_{ij} , c_{ij} , and d_i being constant coefficients.

4. Examples and Simulations

In this section, we give two examples with numerical simulations to illustrate the effectiveness of the proposed method and results.

Example 1. Consider the following impulsive cellular neural networks with piecewise alternately advanced and retarded argument:

$$\begin{aligned} \frac{dx(t)}{dt} &= - \begin{pmatrix} 1.2 & 0 \\ 0 & 0.9 \end{pmatrix} \begin{pmatrix} x_1(t) \\ x_2(t) \end{pmatrix} \\ &\quad + \begin{pmatrix} 0.15 & 0.25 \\ 0.25 & 0.15 \end{pmatrix} \begin{pmatrix} \tanh\left(\frac{x_1(t)}{2}\right) \\ \tanh\left(\frac{x_2(t)}{8}\right) \end{pmatrix} \end{aligned}$$

$$\begin{aligned} &+ \begin{pmatrix} 0.15 & 0.25 \\ 0.25 & 0.15 \end{pmatrix} \begin{pmatrix} \tanh\left(\frac{x_1(3[(t+1)/3])}{8}\right) \\ \tanh\left(\frac{x_2(3[(t+1)/3])}{2}\right) \end{pmatrix} \\ &+ \begin{pmatrix} 0.2 \\ 0.1 \end{pmatrix}, \\ \Delta x|_{t=3k-1} &= \begin{pmatrix} J_{1k}(x_1(3k-1^-)) \\ J_{2k}(x_2(3k-1^-)) \end{pmatrix} \\ &= \begin{pmatrix} \frac{x_1(3k-1^-) - x_1^*}{2} \\ \frac{x_2(3k-1^-) - x_2^*}{3} \end{pmatrix}, \quad k \in \mathbb{N}, \end{aligned} \quad (57)$$

where $x_1^* = 1.943$, $x_2^* = 1.57$. One can check that the point $x^* = (x_1^*, x_2^*)^T$ satisfies the algebraic system

$$-a_i x_i^* + \sum_{j=1}^2 \{b_{ij} f_j(x_j^*) + c_{ij} g_j(x_j^*)\} + d_i = 0, \quad i = 1, 2, \quad (58)$$

approximately. And it is clear that $J_{ik}(x_i^*) = 0$ for $i = 1, 2$. By simple calculation, we can see that $a_* = 0.9$, $\mathcal{L}_1^f = \mathcal{L}_2^g = \mathcal{L}_1^f = 1/2$, $\mathcal{L}_2^f = \mathcal{L}_1^g = 1/8$, $\mathcal{L}_2^g = 1/3$, and $\sup_{t \in \mathbb{R}^+} \mathcal{L}_{i(t)} = \ln(1 + \mathcal{L}_1^f)/3 \approx 0.1351$. Then

$$\begin{aligned} \frac{1 - e^{-l a_*}}{a_*} \left(\sum_{j=1}^n [\mathcal{L}_j^f |b_{1j}| + \mathcal{L}_j^g |c_{1j}|] \right) &\approx 0.1813 < 1, \\ \frac{1 - e^{-l a_*}}{a_*} \left(\sum_{j=1}^n [\mathcal{L}_j^f |b_{2j}| + \mathcal{L}_j^g |c_{2j}|] \right) &\approx 0.1648 < 1, \end{aligned} \quad (59)$$

$$a_1 = 1.2 > 0.275 = \mathcal{L}_1^f \sum_{j=1}^2 |b_{1j}| + \mathcal{L}_1^g \sum_{j=1}^2 |c_{1j}|,$$

$$a_2 = 0.9 > 0.25 = \mathcal{L}_2^f \sum_{j=1}^2 |b_{2j}| + \mathcal{L}_2^g \sum_{j=1}^2 |c_{2j}|.$$

By Theorem 6, we know that the ICNNs with IDEPCA system (57) have a unique equilibrium state x^* , approximately with the error, which is less than 10^{-11} (evaluated by MATLAB).

Moreover, we have

$$\begin{aligned} \tilde{\nu} &= \max_{i \in [1, \dots, n]} \left(\sum_{j=1}^n \mathcal{L}_j^f |b_{ij}| + \mathcal{L}_j^g |c_{ij}| \exp(a_* \cdot (m - l)) \right) \\ &\quad \cdot l \approx 0.7522 < 1, \\ \sum_{j=1}^n (\mathcal{L}_j^f |b_{1j}| + \mathcal{L}_j^g |c_{1j}| (1 - \tilde{\nu})^{-1} \exp(a_* \cdot (m - l))) &\end{aligned}$$

FIGURE 1: (a) The simulation, where the initial value is chosen as $(1, 3)^T$, illustrates that all trajectories uniformly converge to the unique equilibrium $x^* = (1.943, 1.57)^T$ for the ICNNs (57) with impulsive effects. (b) The simulation, where the initial value is chosen as $(1, 3)^T$, illustrates that all trajectories uniformly converge to the unique equilibrium $x^* = (1.943, 1.57)^T$ for the ICNNs (57) without impulsive effects.

$$\begin{aligned}
 &\approx 0.7607 < 0.7648 \approx a_* - \sup_{t \in \mathbb{R}^+} \mathcal{L}_{i(t)}, \\
 &\sum_{j=1}^n (\mathcal{L}_j^f |b_{2j}| + \mathcal{L}_j^g |c_{2j}| (1 - \tilde{\nu})^{-1} \exp(a_* \cdot (m - l))) \\
 &\approx 0.58302 < 0.7648 \approx a_* - \sup_{t \in \mathbb{R}^+} \mathcal{L}_{i(t)}.
 \end{aligned} \tag{60}$$

Thus, according to Theorem 9, the ICNNs with IDEPCA system (57) have a unique globally exponentially stable equilibrium. The numerical simulations, showing the convergence of the unique equilibrium x^* of the ICNNs with and without impulses (57), are given in Figures 1(a) and 1(b).

Example 2. Consider the following impulsive cellular neural networks model with piecewise constant argument:

$$\begin{aligned}
 &\frac{dx(t)}{dt} \\
 &= - \begin{pmatrix} 1.3 & 0 \\ 0 & 0.8 \end{pmatrix} \begin{pmatrix} x_1(t) \\ x_2(t) \end{pmatrix} + \begin{pmatrix} 0.1 & 0.25 \\ 0.25 & 0.35 \end{pmatrix} \\
 &\quad \times \begin{pmatrix} \tanh\left(\frac{x_1(t)}{3}\right) \\ \tanh\left(\frac{x_2(t)}{4}\right) \end{pmatrix} + \begin{pmatrix} 0.16 & 0.26 \\ 0.25 & 0.15 \end{pmatrix} \\
 &\quad \times \begin{pmatrix} \frac{|x_1(4\lceil \frac{t+1}{4} \rceil) + 1| - |x_1(4\lceil \frac{t-1}{4} \rceil) - 1|}{10} \\ \frac{|x_2(4\lceil \frac{t+1}{4} \rceil) + 1| - |x_2(4\lceil \frac{t-1}{4} \rceil) - 1|}{8} \end{pmatrix} \\
 &\quad + \begin{pmatrix} 3 \\ 4 \end{pmatrix},
 \end{aligned}$$

$$\begin{aligned}
 \Delta x|_{t=4k-1} &= \begin{pmatrix} J_{1k}(x_1(4k-1^-)) \\ J_{2k}(x_2(4k-1^-)) \end{pmatrix} \\
 &= \begin{pmatrix} \frac{x_1(4k-1^-) - x_1^*}{x_2(4k-1^-) - x_2^*} \\ \frac{4}{10} \end{pmatrix}, \quad k \in \mathbb{N},
 \end{aligned} \tag{61}$$

where $x_1^* = 2.608$, $x_2^* = 5.719$. One can check that the point $x^* = (x_1^*, x_2^*)^T$ satisfies the algebraic system (29) approximately and it is clear that $J_{ik}(x_i^*) = 0$ for $i = 1, 2$. The output functions are $f_1(x_1) = \tanh(x_1/3)$, $f_2(x_2) = \tanh(x_2/4)$, $g_1(x_1) = (|x_1 + 1| - |x_1 - 1|)/10$, and $g_2(x_2) = (|x_2 + 1| - |x_2 - 1|)/8$.

We can easily obtain that $a_* = 0.8$, $\mathcal{L}_1^f = 1/3$, $\mathcal{L}_2^f = \mathcal{L}_2^g = \mathcal{L}_1^g = 0.25$, $\mathcal{L}_1^g = 0.2$, $\mathcal{L}_2^g = 0.1$, and $\sup_{t \in \mathbb{R}^+} \mathcal{L}_{i(t)} = \ln(1 + \mathcal{L}_1^f)/4 \approx 0.0557$.

Then we give

$$\begin{aligned}
 &\frac{1 - e^{-l a_*}}{a_*} \left(\sum_{j=1}^n [\mathcal{L}_j^f |b_{1j}| + \mathcal{L}_j^g |c_{1j}|] \right) \approx 0.1904 < 1, \\
 &\frac{1 - e^{-l a_*}}{a_*} \left(\sum_{j=1}^n [\mathcal{L}_j^f |b_{2j}| + \mathcal{L}_j^g |c_{2j}|] \right) \approx 0.1996 < 1,
 \end{aligned} \tag{62}$$

$$a_1 = 1.3 > 0.2766 \approx \mathcal{L}_1^f \sum_{j=1}^2 |b_{1j}| + \mathcal{L}_1^g \sum_{j=1}^2 |c_{1j}|,$$

$$a_2 = 0.8 > 0.29 = \mathcal{L}_2^f \sum_{j=1}^2 |b_{2j}| + \mathcal{L}_2^g \sum_{j=1}^2 |c_{2j}|.$$

By Theorem 6, we know that the ICNNs with IDEPCA system (61) have a unique equilibrium.

FIGURE 2: (a) The simulation, where the initial value is chosen as $(3, 3)^T$, illustrates that all trajectories uniformly converge to the unique equilibrium $x^* = (2.608, 5.719)^T$ for the ICNNs (61) with impulsive effects. (b) The simulation, where the initial value is chosen as $(3, 3)^T$, illustrates that all trajectories uniformly converge to the unique equilibrium $x^* = (2.608, 5.719)^T$ for the ICNNs (61) without impulsive effects.

In addition, we have

$$\begin{aligned}
 \tilde{v} &= \max_{i \in [1, \dots, m]} \left(\sum_{j=1}^n \mathcal{L}_j^f |b_{ij}| + \mathcal{L}_j^g |c_{ij}| \exp(a_* \cdot (m-l)) \right) \\
 &\cdot l \approx 0.4615 < 1, \\
 \sum_{j=1}^n (\mathcal{L}_j^f |b_{1j}| + \mathcal{L}_j^g |c_{1j}| (1 - \tilde{v})^{-1} \exp(a_* \cdot (m-l))) \\
 &\approx 0.5826 < 0.7442 \approx a_* - \sup_{t \in \mathbb{R}^+} \mathcal{L}_{i(t)}, \\
 \sum_{j=1}^n (\mathcal{L}_j^f |b_{2j}| + \mathcal{L}_j^g |c_{2j}| (1 - \tilde{v})^{-1} \exp(a_* \cdot (m-l))) \\
 &\approx 0.7286 < 0.7442 \approx a_* - \sup_{t \in \mathbb{R}^+} \mathcal{L}_{i(t)}.
 \end{aligned} \tag{63}$$

From Theorem 9, the ICNNs with IDEPCA system (61) have the unique equilibrium x^* which is globally asymptotically stable and all other solutions of the IDEPCA system (61) converge exponentially to it as $t \rightarrow \infty$. The numerical simulations, showing the convergence of the unique equilibrium x^* of the ICNNs with and without impulses (61), are given in Figures 2(a) and 2(b).

5. Conclusions

This is the first time that impulsive differential equations with alternately advanced and retarded argument have been applied to the model of cellular neural network models, and this paper has provided sufficient conditions guaranteeing the existence, uniqueness, and global exponential stability of the unique equilibrium of the impulsive cellular neural network models for the considered system based on a new IDEPCA integral inequality of Gronwall type and fixed point theorem. In addition, our method gives new ideas not only from the modeling point of view but also from that of theoretical

opportunities since the impulsive cellular neural network model equation involves piecewise constant arguments of both advanced and delayed types. The obtained results could be useful in the design and applications of impulsive cellular neural network models. Furthermore, the examples with numerical simulations are given to show the effectiveness of the proposed method and results.

Acknowledgments

The author thanks the referees and editor very much for their valuable suggestions which made this paper much improved. This research was in part supported by FIBE 01-12 DIUMCE.
