A codimension-4 homoclinic bifurcation with one orbit flip and one inclination flip at principal eigenvalue direction resonance is considered. By introducing a local active coordinate system in some small neighborhood of homoclinic orbit, we get the Poincaré return map and the bifurcation equation. A detailed investigation produces the number and the existence of 1-homoclinic orbit, 1-periodic orbit, and double 1-periodic orbits. We also locate their bifurcation surfaces in certain regions.

1. Introduction and Hypotheses

The study of homoclinic flip bifurcations is comprehensively developed from the last two decades with the beginning work of Yanagida (1987) for homoclinic-doubling bifurcations. Generally there exist two kinds of homoclinic flips, namely the orbit flips and the inclination flips corresponding to non-principal homoclinic orbits or critically twisted homoclinic orbits, respectively. Kisaka et al. in [1, 2] and Naudot in [3] studied some cases of codimension two inclination flips; Morales and Pacifico in [4] and Naudot in [5] considered the orbit flips cases, while Homburg and Krauskopf in [6] proposed several unfoldings of the resonant homoclinic flip bifurcations around the central codimension-three point (the organizing centre) in parameter space to study the qualitative structure of bifurcation curves on a sphere and also that of Oldeman et al. in [7] by a numerical investigation with some software into these bifurcations in a specific three-dimensional vector field.

Recently, Zhang et al. in [8–10] studied a kind of multiple flips homoclinic resonant bifurcation and got the existence of some saddle-node bifurcations and homoclinic-doubling bifurcations. Meanwhile Geng et al. in [11], Lu et al. in [12], and Liu in [13] discussed, respectively, a heterodimensional cycle flip or accompanied by transcritical bifurcation; they found the double and triple periodic orbit bifurcations and gave also some coexistence conditions for homoclinic orbits and periodic orbits.

As mentioned in [6, 7], due to the break of three genericity conditions, there are many complicated homoclinic flips cases to study. In this paper, we confine our attention to a principal eigenvalue resonance of one orbit flip and one inclination flip homoclinic bifurcation. Compared with the above-mentioned work, our subject is very challenging and difficult because of the stronger degeneracy and the higher codimension. By constructing specifically a local active coordinate in a small tubular neighborhood of homoclinic orbit, we establish a regular map and then combine it with a singular map defined by the approximation solutions of system to build Poincaré return map (see also [14]). We obtain the existence of several 1-periodic orbit, 1-homoclinic orbit, and double 1-periodic orbits, as well as some bifurcation surfaces with the analysis of the bifurcation equation.

We first consider a $C^{r}$ system

$$\dot{z} = f (z) + g (z, \mu)$$  \hspace{1cm} (1)

and its unperturbed system

$$\dot{z} = f (z),$$  \hspace{1cm} (2)
where $r \geq 3$, $z \in \mathbb{R}^4$, $\mu \in \mathbb{R}^l$, $l \geq 4$, $0 < |\mu| \ll 1$, $f(0) = 0$, and $g(0, \mu) = g(z, 0) = 0$. Suppose that the linearization $Df(0)$ has four simple real eigenvalues $\lambda_1, \lambda_2, -\rho_1$, and $-\rho_2$ with $\lambda_2 > \lambda_1 > 0 > -\rho_1 > -\rho_2$. Accordingly, the stable manifold $W_s$ and the unstable manifold $W_u$ are both two-dimensional. Let $W_s^u$ and $W_u^s$ be the strong stable manifold and the strong unstable manifold of the saddle $z = 0$, respectively. Assume further that system (2) has a homoclinic orbit $\Gamma = \{z = r(t) : t \in \mathbb{R}, r(\pm \infty) = 0\}$. Hereinafter, our arguments will spread based on the following three hypotheses.

(H1) **Resonance.** $\lambda_1(\mu) = \rho_1(\mu)$, $|\mu| \ll 1$, where $\lambda_1(0) = \lambda_1$ and $\rho_1(0) = \rho_1$.

(H2) **Orbit Flip.** Define $e^r = \lim_{r \to -\infty} r(t)/|r(t)|$; $e^s = \lim_{r \to +\infty} r(t)/|r(t)|$; then $e^r \in T_0 W_s^u$ and $e^s \in T_0 W_u^s$ are unit eigen-vectors corresponding to $\lambda_1$ and $-\rho_1$, respectively, where $T_0 W_s^u$ (resp., $T_0 W_u^s$) is the tangent space of the corresponding manifold $W_s^u$ (resp., $W_u^s$) at the saddle $z = 0$.

(H3) **Inclination Flip.** Let $e_u^r$ and $e_u^s$ be the unit eigenvectors corresponding to $\lambda_2$ and $-\rho_2$, respectively, and
\[
\lim_{t \to +\infty} \left\{ T_r(0) W_s^u, T_r(0) W_u^s, e_u^r \right\} = \mathbb{R}^4, \\
\lim_{t \to -\infty} \left\{ T_r(0) W_s^u, T_r(0) W_u^s, e_u^s \right\} = \mathbb{R}^4.
\]

Remark 1. Hypothesis (H2) is called an orbit flip because homoclinic orbit trends from the weak unstable manifold toward the strong stable manifold. Hypothesis (H3) means an inclination flip for its equivalence to
\[
T_r(0) W_s^u \to \text{span} \{ e_u^r, e^s \}, \\
T_r(0) W_u^s \to \text{span} \{ e_u^s, e^r \}.
\]

### 2. Poincaré Return Map

This section treats mainly the establishment of Poincaré return map with two steps. To begin we first need to transform system (1) into a normal form in some neighborhood of the origin $O$.

It is well known that there are always two $C^r$ and $C^{r-1}$ transformations successively, also by the stable (or unstable) manifold theorem in [15], to straighten the local manifolds $W_s^u$ and $W_u^s$ as $W_s^{loc} = \{ z \in U, x = u \ = \ 0 \}$ and $W_u^{loc} = \{ z \in U, y = v = 0 \}$, respectively, $W_s^{loc} = \{ z \in U, x = y = u = 0 \}$ (resp., $W_u^{loc} = \{ z \in U, x = y = v \}$); see [8–10]. Notice that now $\Gamma \cap W_s^{loc} = \{ z \in U, u = u(x), y = v = 0 \}$ and $\Gamma \cap W_u^{loc} = \Gamma^{u\text{loc}}$, where $z = (x, y, u, v) \in \mathbb{R}^4$, and $u(0) = u'(0) = 0$. Thus, system (1) can be changed to a $C^{r-2}$ form in the neighborhood $U$ as follows:
\[
\dot{x} = [\lambda_1(\mu) + a(\mu) xv + o(|xv|)] x \\
+ O(u) \left[ O(x^2v) + O(y) \right], \\
\dot{y} = [-\rho_1(\mu) + b(\mu) xv + o(|xv|)] y \\
+ O(v) \left[ O(xvy) + O(u) \right],
\]
and its adjoint system
\[
\dot{z} = -(Df(r(t)))^* z. 
\]
Lemma 2. There exists a fundamental solution matrix \( Z(t) = (z_1(t), z_2(t), z_3(t), z_4(t)) \) of system (8) satisfying

\[
Z(-T) = \begin{pmatrix}
  w_{11} & w_{12} & 0 & w_{41} \\
  w_{12} & 0 & 0 & w_{42} \\
  w_{13} & w_{32} & 1 & w_{43} \\
  0 & 0 & 0 & w_{44}
\end{pmatrix},
\]

(10)

\[
Z(T) = \begin{pmatrix}
  0 & 0 & w_{31} & 0 \\
  w_{14} & w_{22} & 1 & 0 \\
  w_{32} & w_{33} & 0 & 0 \\
  0 & 1 & w_{34} & 0
\end{pmatrix},
\]

where \( z_i(t) \in (T_{r(T)}W^u)^c \cap (T_{r(T)}W^s)^c \), \( z_2(t) = -\dot{r}(t)/|\dot{r}(T)| \in T_{r(T)}W^s \), \( z_3(t) \in T_{r(T)}W^u \), and \( w_{12}w_{21}w_{31}w_{44} \neq 0 \). Moreover, \( |w_{31}| < 1 \). For \( r(T), 0 = 1, i = 2, \) and \( i \neq 4 \) for \( T \to +\infty \).

Proof. Notice that the tangent subspace \( T_{r(T)}W^u \) is invariant and \( W^s \cap U \) is straightened to be \( U \) axis; it is possible to choose \( z_2(T) = (0, 0, 1, 0) \) since \( z_3(T) \in T_{r(T)}W^u \). While for \( w_{31} \neq 0 \), it is because \( \lim_{T \to +\infty} T_{r(T)}W^u \) corresponding to \( x \) axis.

As to \( z_2(0) \) or \( z_2(T), i = 1, 2, 4 \), one may refer to [8,9] for the similar proof, but we omit the details here.

Remark 3. The matrix \((Z^{-1}(t))^*\) is a fundamental solution matrix of system (9). We denote it as \( \Phi(t) = (\phi_1(t), \phi_2(t), \phi_3(t), \phi_4(t)) = (Z^{-1}(t))^* \); then \( \phi_i(t) \in (T_{r(T)}W^u)^c \cap (T_{r(T)}W^s)^c \) is bounded and tends to zero exponentially as \( |t| \to +\infty \). Due to \( \phi(t), z_j(t) \geq 1 \) and \( z_j(t) \) tends exponentially to infinity.

In fact, \((z_1(t), z_2(t), z_3(t), z_4(t))\) can be regarded as a new local coordinate system along \( \Gamma \). So we may make a coordinate change as

\[
s(t) = r(t) + Z(t)N
\]

(11)

\[
= r(t) + z_1(t)n_1 + z_3(t)n_3 + z_4(t)n_4,
\]

where \( N = N(t) = (n_1(t), 0, n_3(t), n_4(t))^t \). Note that the new \( s(t) \) should satisfy system (1); that is,

\[
s(t) = f(s(t)) + g(s(t), \mu) = f(r(t) + Z(t)N) + g(r(t) + Z(t)N, \mu).
\]

An asymptotic expansion with respect to \( r(t) \) shows that

\[
n_i = \phi_i^*(t) \mu + O(\|\mu\|^2)
\]

+ \( O(|N|^2) + O(\|\mu\||N)|, \quad i = 1, 3, 4, \)

Via integrating both sides from \(-T\) to \( T \) of this equation, one can finally obtain

\[
n_i(T) = n_i(-T) + M_i\mu + \text{h.o.t.}, \quad i = 1, 3, 4,
\]

Equation (14) defines exactly the map \( F_1 : S \rightarrow S \); \( N(-T) \to N(T) \) under the new coordinate system; see Figure 1(b).

In order to combine \( F_0 \) and \( F_1 \) into the Poincaré return map, we still need to establish a relationship between the original and the new coordinate systems. In doing so, recall that \( z(t) = r(t) + Z(t)N(t) \); then by taking time \( t = T \) and \( T = -T \), respectively, together with \( z(T) = \phi_1(x_{2j}, y_{2j}, u_{2j}, v_{2j}) \in S \), \( z(-T) = \phi_1(x_{2j+1}, y_{2j+1}, u_{2j+1}, v_{2j+1}) \in S \) and \( N(T) = (n_{2j,1}, 0, n_{2j,3}, n_{2j,4}), N(-T) = (n_{2j+1,1}, 0, n_{2j+1,3}, n_{2j+1,4}) \), \( j = 0, 1, 2, \ldots \), we obtain immediately the following formulas:

\[
n_{2j,1} = u_{2j} - w_{33}w_{31}x_{2j},
\]

\[
n_{2j,3} = w_{33}x_{2j},
\]

\[
n_{2j,4} = y_{2j} - w_{14}u_{2j} - (w_{33}w_{33} - w_{34})w_{31}x_{2j},
\]

\[
n_{2j+1,1} = w_{12}^{-1}y_{2j+1} - w_{42}w_{14}^{-1}w_{44}^{-1}v_{2j+1},
\]

\[
n_{2j+1,3} = u_{2j+1} - \delta_u - w_{13}w_{14}^{-1}y_{2j+1}
\]

\[
+ (w_{13}w_{42}w_{14}^{-1} - w_{33})w_{44}^{-1}v_{2j+1},
\]

\[
n_{2j+1,4} = w_{44}^{-1}v_{2j+1},
\]

\[
x_{2j+1} = \delta, \quad v_{2j} = \delta.
\]
With all of the above, the Poincaré return map is given as $F = F_1 * F_0$. Therefore, the associated successor function $G(s, u_1, y_0) = (G_1, G_2, G_3, G_4) = F(q_0) - q_0$ is

$$G(s, u_1, y_0) = w_{42} w_{44}^{-1} s^3 \delta^2 + w_{32} w_{33}^3 \delta s,$$

and $G_4 = M_4 \mu + h.o.t.$

$$G(s, u_1, y_0) = w_{32} - w_{33} w_{43}, \quad G_4 = M_4 \mu + h.o.t.$$

where $G = \partial(G_1, G_2, G_3, G_4) / \partial Q(u_1, y_0)$. Implicit function theorem reveals that (16) has a unique solution as

$$s = s(\mu), \quad u_1 = u_1(\mu), \quad y_0 = y_0(\mu).$$

with $s(0) = 0, u_1(0) = 0$, and $y_0(0) = 0$. It means that system (1) has a unique periodic orbit as $s > 0$ or a unique homoclinic orbit as $s = 0$, and they cannot coexist.

**Theorem 4.** Suppose that $M_1 \neq 0$ and $w_{33} \neq 0$ are true; then system (1) has a unique 1-periodic orbit near $\Gamma$ for $w_{33} \neq 0$ or has a unique 1-homoclinic orbit $\Gamma_0$ near $\Gamma$ as $\mu \in H^1$ with $M_1 \mu + h.o.t. = 0$, and they do not coexist.

**Proof.** Clearly $F(\mu) = 0$ has a small positive solution $s = -\delta^{-1} w_{33}^{-1} w_{31} M_1 \mu + h.o.t.$, for $w_{33} > 0$, and has a zero solution $s = 0$ for $\mu \in H^1$ which is a codimension-one hypersurface.

In the following part we restrict our attention on the case $w_{33} = 0$, $2 \lambda_1 > \lambda_2 > \rho_2$. Define

$$R_{\pm} = \{ \mu : \lambda_2^2 \mu > \rho_2 \},$$

where $\lambda_1, \lambda_2, \rho_2$ are defined in (18). Then $F(s, \mu) = 0$ holds; then $F(s, \mu) = 0$ has a unique small positive solution $s = w_{33} \neq 0$ and $w_{33} \neq 0$ hold; then $F(s, \mu) = 0$ has a unique small positive solution $s \in (0, s^*)$ for $\mu \in E^{-1}$, where $s^* = [w_{33} w_{44}^3 \delta^2 (2 w_{12} M_1 \mu + M_4 \mu)]^{1/\lambda_2}$.

Then there are firstly the following conclusions based on an analysis of the relative position of the line $W = P(s, \mu)$ and the curve $W = Q(s, \mu)$.

**Lemma 5.** Suppose that $2 \lambda_1 > \lambda_2 > \rho_2$, $w_{33} = 0$, and $w_{34} \neq 0$ hold; then $F(s, \mu) = 0$ has a unique small positive solution $s \in (0, s^*)$ for $\mu \in E^{-1}$, where $s^* = [w_{33} w_{44}^3 \delta^2 (2 w_{12} M_1 \mu + M_4 \mu)]^{1/\lambda_2}$.

**Proof.** It is clear that

$$P(0, \mu) = w_{12} M_1 \mu + h.o.t., \quad Q(0, \mu) = 0,$$

$$Q'(s, \mu) = \rho_2 \lambda_1^{-1} w_{42} w_{44}^{-1} \delta^2 (\eta^1 \lambda_1)^{-1} + h.o.t..$$

Therefore, the line $W = P(s, \mu)$ intersects the curve $W = Q(s, \mu)$ at a unique point $s$ for $\mu \in E^{-1}$. Notice that $Q(s^*, \mu) = w_{12} M_1 \mu + M_4 \mu + h.o.t. > w_{12} M_1 \mu + M_4 \mu^* + h.o.t. = P'(s^*, \mu), \quad s^* \in (0, s^*)$.

$\square$
Theorem 6. Suppose that $2\lambda_1 > \lambda_2 > \rho_2, w_{33} = 0, \text{and } w_{42} \neq 0$ hold; then system (1) has exactly a unique (resp., not any) 1-periodic orbit for $\mu \in E^0_1$ (resp., $\mu \in E^{11}_1 \cap R^{11}_{14}$).

Proof. From Lemma 5, we know that $F(s, \mu) = 0$ has exactly a unique small positive solution for $\mu \in E^0_1$ which corresponds exactly to a 1-periodic orbit of system (1). Moreover, $F(s, \mu) = 0$ does not have any small positive solutions for $\mu \in E^{11}_1 \cap R^{11}_{14}$.

Theorem 7. Suppose that $2\lambda_1 > \lambda_2 > \rho_2, w_{33} = 0, \text{and } w_{42} \neq 0$ hold; then, for $\mu \in E^{11}_1 \cap R^{11}_{14}$ and $\text{Rank } (M_1, M_4) = 2$, system (1) has a unique double 1-periodic orbit near $\Gamma$ on the bifurcation surface

$$SN^1 : w_{12} M_1 \mu + \frac{\rho_2 - \lambda_1}{\rho_4} M_1 \mu = \left( \frac{\lambda_1 w_{44} M_1 \mu}{\rho_2 w_{42} \delta} \right)^{\lambda_i/(\rho_i - \lambda_i)} \times (M_4 \mu + \frac{\rho_1}{\rho_4})^{\rho_j/(\rho_j - \lambda_i)} + \text{h.o.t.},$$

which has a normal vector $M_1$ at $\mu = 0$. The corresponding double positive zero point is

$$s_* = \left( \frac{\lambda_1 w_{44} M_1 \mu}{\rho_2 w_{42} \delta} \right)^{\lambda_i/(\rho_i - \lambda_i)} + \text{h.o.t.}$$

as $\mu \in E^0_1$ (see Figure 2(a)).

Proof. We know that the existence of a double 1-periodic orbit corresponds to the equations

$$P(s, \mu) = Q(s, \mu), P'(s, \mu) = Q'(s, \mu), \text{and } P''(s, \mu) \neq Q''(s, \mu),$$

that is,

$$M_{4\mu} + w_{12} M_1 \mu = w_{42} w_{44}^{-1} \delta^{s_0/(\rho_4 - \lambda_1)} + \delta_i w_{12} s^{\lambda_i/(\rho_i - \lambda_1)} - w_{12} M_1 \mu s^{\lambda_j/(\rho_j - \lambda_1)} - w_{42} w_{33}^{-1} \delta s^{\lambda_j/(\rho_j - \lambda_1)} - w_{44}^{-1} \delta^{s/(\rho_i + \rho_2 - \lambda_1)} + w_{12} w_{33}^{-1} \delta^{s/(\rho_i + \lambda_j - \lambda_1)} + \text{h.o.t.},$$

having solutions. Indeed, the second equation of (26) permits the double positive zero point $s_*$ as $\mu \in E^0_1$. Putting it into the first equation of (26), there is

$$M_{4\mu} \left( \frac{\lambda_1 w_{44} M_4 \mu}{\rho_2 w_{42} \delta} \right)^{\lambda_i/(\rho_i - \lambda_i)} + w_{12} M_1 \mu + \delta_i w_{12} s^{\lambda_i/(\rho_i - \lambda_1)} - w_{42} w_{33}^{-1} \delta s^{\lambda_j/(\rho_j - \lambda_1)} - w_{44}^{-1} \delta^{s/(\rho_i + \rho_2 - \lambda_1)} + w_{12} w_{33}^{-1} \delta^{s/(\rho_i + \lambda_j - \lambda_1)} + \text{h.o.t.}$$

Then $SN^1$ exists for $\mu \in E^{11}_1 \cap R^{11}_{14}$. \Box

From the above proof, we see that, when $M_{4\mu} > 0$ and $w_{12} M_1 \mu < 0$, the line $W = P(s, \mu)$ has a positive slope lying under the curve $W = Q(s, \mu)$ when $w_{42} w_{44} > 0$, so if $w_{12} M_1 \mu > 0$.
increases, the line must intersect the curve at two sufficiently small positive points, which can be equal to the existence of two 1-periodic orbits of system (1). For $M_2\mu < 0$, $\omega_{42}\omega_{43} < 0$, and $\omega_{12}M_1\mu > 0$, the arguments are similar. So we have immediately a complement of Theorem 7.

**Corollary 8.** Assume that the hypotheses of Theorem 7 are valid, system (1) then has two (resp., not any) 1-periodic orbits near $\Gamma$ when $\mu$ lies on the side of $SN^1$ which points to the direction $(\text{sgn}\,\omega_{12}\omega_{42}\omega_{43}) M_1$ (resp., in the opposite direction) (see Figures 2(b) and 2(c)).

As Melnikov functions generally play an important role in bifurcation study, the following theorem shows also the existence of some double 1-periodic orbits relying on the investigation of $M_i = 0$ for $i = 1, 3, 4$.

**Theorem 9.** Suppose $2\lambda_1 > \lambda_2 > \rho_1$, $\omega_{33} = 0$, and $\omega_{42} \neq 0$ are valid; then the following applies.

1. For $M_1 = 0$ or $M_1^2 + M_2^2 = 0$, system (1) has exactly one 1-homoclinic orbit and one (resp., not any) 1-periodic orbit near $\Gamma$ and they (resp., do not) coexist as $\mu \in E_0^{00}$ (resp., $\mu \in E_1^{11}$).

2. For $M_4 = 0$, system (1) has exactly one (resp., not any) 1-periodic orbit near $\Gamma$ as $\mu \in E_0^{01}$ (resp., $\mu \in E_1^{11} \cap R_1^{01}$). System (1) has a unique double 1-periodic orbit near $\Gamma$ as $\mu \in E_0^{01} \cap R_1^{01}$ and $\mu \in E_1^{11} \cap R_1^{01}$ and Rank $(M_1, M_4) = 2$. Accordingly, the double 1-periodic orbit bifurcation surface is $SN^1 : \omega_{12}M_1\mu + ((\rho_2 - \lambda_1)\omega_{42}\lambda_1\omega_{33}(\lambda_1\omega_{42}M_1\mu/\rho_2\omega_{42}\lambda_1)^{\rho_2/(\rho_2 - \lambda_1)} + \omega_{12}M_4\mu) + \omega_{42}\omega_{43}h.o.t. = 0$ with a normal vector $M_1$ at $\mu = 0$, and it may generate two 1-periodic orbits when $\mu$ lies in the direction $(\text{sgn}\,\omega_{42}\omega_{43}\omega_{43}) M_1$ of $SN^1$ and no such a 1-periodic orbit in the opposite direction.

3. For $M_4 = 0$ or $M_1^2 + M_2^2 = 0$, system (1) has only one (resp., not any) 1-periodic orbit near $\Gamma$ as $\mu \in E_0^{01}$ (resp., $\mu \in E_1^{11}$).

4. For $M_1^2 + M_2^2 = 0$, system (1) does not have any 1-periodic orbit near $\Gamma$.

5. For $M_1^2 + M_2^2 + M_3^2 = 0$, system (1) has only one 1-homoclinic orbit near $\Gamma$.

**Proof.** When $M_1 = 0$ or $M_1^2 = 0$, $F(s, \mu) = 0$. For some $s \in R$ and $\mu \in R_0$, system (1) has exactly one 1-homoclinic orbit and one (resp., not any) 1-periodic orbit near $\Gamma$ as $\mu \in E_0^{01}$ (resp., $\mu \in E_1^{11} \cap R_1^{01}$). System (1) has a unique double 1-periodic orbit near $\Gamma$ as $\mu \in E_0^{01} \cap R_1^{01}$ and $\mu \in E_1^{11} \cap R_1^{01}$ and Rank $(M_1, M_4) = 2$. Accordingly, the double 1-periodic orbit bifurcation surface is $SN^1 : \omega_{12}M_1\mu + ((\rho_2 - \lambda_1)\omega_{42}\lambda_1\omega_{33}(\lambda_1\omega_{42}M_1\mu/\rho_2\omega_{42}\lambda_1)^{\rho_2/(\rho_2 - \lambda_1)} + \omega_{12}M_4\mu) + \omega_{42}\omega_{43}h.o.t. = 0$ with a normal vector $M_1$ at $\mu = 0$, and it may generate two 1-periodic orbits when $\mu$ lies in the direction $(\text{sgn}\,\omega_{42}\omega_{43}\omega_{43}) M_1$ of $SN^1$ and no such a 1-periodic orbit in the opposite direction.

**Remark 10.** Notice that, in Theorem 9 (1) and (5), $F(s, \mu) = 0$ has a solution $s = 0$, which means that system (1) has a codimension-1 1-homoclinic orbit (see Figure 3(a)), so the existing homoclinic orbit is no longer orbit flip for $y_0 = M_4\mu + h.o.t. \neq 0$. But if $y_0 = 0$, an orbit flip homoclinic orbit could still exist, where $y_0$ is given by $G_4 = 0$; see Figure 3(b).

**Remark 11.** There still exist some double 1-periodic orbits or triple 1-periodic orbits for the case $\omega_{42} = 0$ and $\omega_{43} \neq 0$; one may pursue the similar process to discuss, so we leave it here.
