We investigate a mathematical model introduced by Shikhmurzaev to remove singularities that arise when classical hydrodynamic models are applied to certain physical phenomena. The model is described as a free boundary problem consisting of the Navier-Stokes equations and a surface mass balance equation. We prove the local-in-time solvability in Hölder spaces.

1. Introduction

Let a time-dependent bounded domain $\Omega_t \subset \mathbb{R}^3$ with the outer boundary $\Gamma_t \equiv \partial\Omega_t$ be filled with an incompressible viscous fluid, and let Γ_t represent the interface. In Ω_t , we assume that the flow is governed by the Navier-Stokes equations:

$$\frac{\partial \mathbf{v}}{\partial t} + (\mathbf{v} \cdot \nabla) \mathbf{v} + \nabla p - \nu \Delta \mathbf{v} = \mathbf{0}, \quad \nabla \cdot \mathbf{v} = 0, \quad (1)$$

where $\mathbf{v}$ is the velocity, p is the pressure, and ν , which is assumed to be a positive constant, is the kinematic viscosity.

On Γ_t , we assume the following equations:

$$\Pi \mathbf{T}(\mathbf{v}, p) \mathbf{n} = \bar{\nabla} \sigma, \quad \mathbf{n} \cdot \mathbf{T}(\mathbf{v}, p) \mathbf{n} = \sigma H, \quad (2)$$

$$\frac{D\rho^s}{Dt} + \rho^s \bar{\nabla} \cdot \mathbf{v}^s = \rho (\mathbf{v} - \mathbf{v}^s) \cdot \mathbf{n}, \quad (3)$$

$$(\mathbf{v} - \mathbf{v}^s) \cdot \mathbf{n} = -\frac{\rho_e^s - \rho^s}{\rho \tau}, \quad \Pi (\mathbf{v} - \mathbf{v}^s) = -\chi \bar{\nabla} \sigma, \quad (4)$$

$$\sigma = \gamma (\bar{\rho} - \rho^s). \quad (5)$$

Here $\mathbf{v}^s$ and ρ^s are the velocity and the density of surface layer, respectively. $\mathbf{T}(\mathbf{v}, p) = \nu \mathbf{D}(\mathbf{v}) - p\mathbf{I}$ is the stress tensor, where $\mathbf{D}(\mathbf{v}) = ((\partial v_i / \partial x_j) + (\partial v_j / \partial x_i))_{i,j=1,2,3}$ is the velocity deformation tensor. H is the twice mean curvature of Γ_t at the point x , which is negative if Ω_t is convex in the neighborhood

of x . $\mathbf{n}$ is the unit outward normal to Γ_t at the point x . Π is the projection operator onto the tangent plane at the point x on Γ_t . D/Dt denotes the derivative along the trajectory of particle on Γ_t . $\bar{\nabla}$ is the gradient restricted to the surface. $\rho, \rho_e^s, \tau, \chi, \gamma, \bar{\rho}$ are positive constants; in particular, ρ is the density of the bulk and τ is the characteristic time scale over which the surface density ρ^s relaxes to its equilibrium value ρ_e^s .

Finally, to complete the problem, we give the initial conditions:

$$\mathbf{v}|_{t=0} = \mathbf{v}_0 \quad \text{on } \bar{\Omega} \equiv \bar{\Omega}_0, \quad \rho^s|_{t=0} = \rho_0 \quad \text{on } \Gamma \equiv \Gamma_0. \quad (6)$$

It is known that singularities arise when the classical hydrodynamic equations and modeling assumptions are applied to certain physical phenomena. For example, the application of the classical no-slip boundary condition to the spreading of a drop on a plate gives rise to a nonintegrable shear stress, and the application of the classical kinematic condition at the free boundary to the formation of a cusp on a free surface of a viscous fluid leads to an infinite energy dissipation in the fluid (e.g., refer to [1] and the references therein).

To remove the above mentioned singularities, we are required to modify classical boundary conditions by taking into account molecular interaction near interfaces. The molecule in the liquid region which is very close to another phases experiences an asymmetric force due to the presence of another materials. This gives rise to the variation in the

density in the liquid region near to the adjacent phase, and the surface tension occurs as a result of this variation in density. The thin layer in the liquid region in which the above mentioned density variation occurs is called the surface layer.

Through [1–4], Shikhmurzaev developed a theory to remove the above mentioned singularities by introducing a surface layer which is treated as a separate phase. In this theory, the no-slip condition assumed in classical models for dynamic wetting processes is modified as the Navier-slip condition through thermodynamic considerations on the surface layer (refer to [2, 3]). The formation of a free surface cusp associated with fluid flow is also investigated in [4]. In [4], the cusp formation is modeled as an interface disappearance process. In this model, an internal surface stretching from the cusp, which is referred to as “the surface-tension-relaxation tail”, is introduced. The above mentioned singularity associated with the modeling of cusp formation arises owing to the absence of viscous stress at the cusp with which the surface tension acting from the liquid surface is balanced. In this model, the surface tension at the cusp can be balanced by shear stresses acting on this tail.

The problem (1)–(6) is a model describing the behavior of an isolated liquid drop in which the interface is modeled as a surface layer based on Shikhmurzaev's theory. The dynamics of the liquid in this layer are governed by (3) which represents conservation of mass. The right-hand side of (3) represents the source consisting of a flow of molecules from the bulk. Equations in (4) are conditions that minimize the rate of entropy production in the surface layer. Equation (5) represents a linearized state equation in the surface layer (refer to [1] for details). In Shikhmurzaev's theory, the surface layer is modeled as a sharp interface as a result of a continuum approximation. Thus, in the above problem, the surface layer is described by the equations given in (3)–(5) defined on a geometric surface, and the behavior of the surface layer is related to (1) in the bulk through the boundary conditions given in (2).

In the present paper, we prove the local-in-time classical solvability of problem (1)–(6). As is mentioned above, this model is important as a basic model to describe the above mentioned physical phenomena; however, as far as the author knows, any rigorous proofs on its solvability have not been given. In the present paper, we consider the case where the mass exchange between the interface and the bulk does not occur. As is seen in Section 2, under such an assumption, we can reformulate our problem as a problem defined in a domain with a fixed known boundary by introducing Lagrangian coordinates, and in Section 3, we construct a unique solution of the reformulated problem in Hölder spaces with the aid of the method of successive approximations.

2. Reformulation of the Problem

In this section, we reformulate our problem in Lagrangian coordinates. By Lagrangian coordinates we mean the initial coordinates of the fluid particles. In the case where no exchange of molecules occurs between the surface and the

bulk, (4)¹ is reduced to $\mathbf{v} \cdot \mathbf{n} = \mathbf{v}^s \cdot \mathbf{n}$. This relation indicates that the following kinematic condition at the interface is satisfied: the interface consists of the particles located at the interface at the initial time. This circumstance enables us to relate each point $x \in \bar{\Omega}_t$ to its initial point $\xi \in \bar{\Omega}$ by relation (10) given below.

Before reformulating our problem, we rewrite (3) as a nonlinear parabolic equation on Γ_t with the time derivative $\bar{D}\rho^s/\bar{D}t$, where $\bar{D}\rho^s/\bar{D}t$ denotes the derivative along the trajectory of particle on the interface with velocity $\mathbf{v}$. Noting the following relation (e.g., see [5]):

$$\left(\frac{D\rho^s}{Dt} \right)_n = \frac{D\rho^s}{Dt} - \mathbf{v}^s \cdot \bar{\nabla}\rho^s = \frac{\bar{D}\rho^s}{\bar{D}t} - \mathbf{v} \cdot \bar{\nabla}\rho^s, \quad (7)$$

where $(D\rho^s/Dt)_n$ represents the derivative along the trajectory which is normal to the interface, (3) can be written as

$$\frac{\bar{D}\rho^s}{\bar{D}t} + \rho^s \bar{\nabla} \cdot \mathbf{v}^s = (\mathbf{v} - \mathbf{v}^s) \cdot \bar{\nabla}\rho^s. \quad (8)$$

Then eliminating $\mathbf{v}^s$ from the above equation with the aid of the relation (4)², we obtain the following equation:

$$\begin{aligned} \frac{\bar{D}\rho^s}{\bar{D}t} - \chi\gamma\rho_0^s \bar{\nabla}^2 \rho^s &= -\rho^s \bar{\nabla} \cdot \mathbf{v} \\ &+ \chi\gamma \left\{ (\rho^s - \rho_0^s) \bar{\nabla}^2 \rho^s + \bar{\nabla}\rho^s \cdot \bar{\nabla}\rho^s \right\}. \end{aligned} \quad (9)$$

Now let us reformulate our problem. The Lagrangian and Eulerian coordinates are related by

$$x = X_u(\xi, t) \equiv \xi + \int_0^t \mathbf{u}(\xi, \tau) d\tau, \quad (10)$$

where $\mathbf{u}(\xi, \tau)$ is the velocity at time t of the particle which was located at ξ at $t = 0$. By changing the variables from x to ξ by relation (10), problem (1)–(6) is reformulated as the following problem defined in the cylindrical domain $\Omega_{0T} = \Omega \times (0, T)$ with the lateral boundary $\Gamma_{0T} \equiv \Gamma \times (0, T)$:

$$\frac{\partial \mathbf{u}}{\partial t} - \nu \nabla_u^2 \mathbf{u} + \nabla_u q = \mathbf{0}, \quad \nabla_u \cdot \mathbf{u} = 0 \quad \text{in } \Omega_{0T}, \quad (11)$$

$$\Pi \Pi_u \mathbf{T}_u(\mathbf{u}, q) \mathbf{n}_u = \Pi \nabla_{\Gamma_t} \theta,$$

$$\mathbf{n} \cdot \mathbf{T}_u(\mathbf{u}, q) \mathbf{n}_u = \theta \nabla_{\Gamma_t}^2 X_u(\xi, t) \Big|_{\xi \in \Gamma} \cdot \mathbf{n} + \mathbf{n} \cdot \nabla_{\Gamma_t} \theta,$$

$$\frac{\partial r^s}{\partial t} - \chi\gamma\rho_0^s \nabla_{\Gamma_t}^2 r^s \quad (12)$$

$$= -r^s \nabla_{\Gamma_t} \cdot \mathbf{u} + \chi\gamma \left\{ (r^s - \rho_0^s) \nabla_{\Gamma_t}^2 r^s + \nabla_{\Gamma_t} r^s \cdot \nabla_{\Gamma_t} r^s \right\},$$

$$\theta = \gamma(\bar{\rho} - r^s) \quad \text{on } \Gamma_{0T},$$

$$\mathbf{u}|_{t=0} = \mathbf{v}_0 \quad \text{on } \bar{\Omega}, \quad r^s|_{t=0} = \rho_0^s \quad \text{on } \Gamma. \quad (13)$$

In (11)–(13), $\mathbf{u}$, q and r^s are $\mathbf{v}(X_u(\xi, t), t)$, $p(X_u(\xi, t), t)$, and $\rho^s(X_u(\xi, t), t)$, respectively. Consider $\nabla_u = (\mathcal{J}_u^{-1})^t \nabla \equiv \mathcal{J}_u^* \nabla$; here $\mathcal{J}_u$ denotes the Jacobian matrix of X_u , and the notation

A^t means the transpose of the matrix A . $\mathbf{n}$ is the outward unit normal to Γ at the point ξ , $\mathbf{n}_u = \mathcal{J}_u^* \mathbf{n} / |\mathcal{J}_u^* \mathbf{n}|$, and Π and Π_u are the operators defined by $\Pi \mathbf{f} = \mathbf{f} - (\mathbf{f} \cdot \mathbf{n}) \mathbf{n}$ and $\Pi_u \mathbf{f} = \mathbf{f} - (\mathbf{f} \cdot \mathbf{n}_u) \mathbf{n}_u$, respectively. $\mathbf{T}_u(\mathbf{u}, q)$ is the tensor with the elements $\nu \sum_{k=1}^3 (A_{jk}(\partial u_i / \partial \xi_k) + A_{ik}(\partial u_j / \partial \xi_k)) - p \delta_{ij}$, where A_{ij} is the (i, j) -element of $\mathcal{J}_u^*$, and δ_{ij} is Kronecker's delta. The operators $\nabla_{\Gamma_t} f$ and $\nabla_{\Gamma_t} \cdot \mathbf{A}$ are defined by

$$\begin{aligned} \nabla_{\Gamma_t} f &= \sum_{\alpha, \beta=1,2} g^{\alpha\beta} \frac{\partial f}{\partial s_\beta} \frac{\partial X_u(s)}{\partial s_\alpha}, \\ \nabla_{\Gamma_t} \cdot \mathbf{A} &= \frac{1}{\sqrt{g}} \sum_{\alpha=1,2} \frac{\partial}{\partial s_\alpha} \sqrt{g} A_\alpha, \end{aligned} \quad (14)$$

where $g = \det(g_{\alpha\beta})_{\alpha, \beta=1,2}$, $g_{\alpha\beta} = (\partial X_u(s) / \partial s_\alpha) \cdot (\partial X_u(s) / \partial s_\beta)$, $g^{\alpha\beta}$ denote the components of the inverse matrix of $(g_{\alpha\beta})_{\alpha, \beta=1,2}$, $X_u(s) = X_u(\xi(s), t)$, $s = (s_1, s_2)$ denotes the local coordinates on Γ , and A_α denotes the components of the vector $\mathbf{A}$ with respect to the basis $(\partial X_u(s) / \partial s_\alpha)$, $\alpha = 1, 2$. Finally, the operator $\nabla_{\Gamma_t}^2 f$ is defined as

$$\nabla_{\Gamma_t}^2 f = \nabla_{\Gamma_t} \cdot \nabla_{\Gamma_t} f = \frac{1}{\sqrt{g}} \sum_{\alpha, \beta=1,2} \frac{\partial}{\partial s_\alpha} \sqrt{g} g^{\alpha\beta} \frac{\partial f}{\partial s_\beta}. \quad (15)$$

Note that in derivation of (12)², we have used the formula $H\mathbf{n} = \bar{\nabla}^2 x \equiv \bar{\nabla}^2 X_u(\xi, t)$. Note also that although (12)^{1,2} are different from the following formulas which are obtained directly from (2):

$$\begin{aligned} \Pi_u \mathbf{T}_u(\mathbf{u}, q) \mathbf{n}_u &= \nabla_{\Gamma_t} \theta, \\ \mathbf{n}_u \cdot \mathbf{T}_u(\mathbf{u}, q) \mathbf{n}_u &= \theta \nabla_{\Gamma_t}^2 X_u(\xi, t) \Big|_{\xi \in \Gamma} \cdot \mathbf{n}_u, \end{aligned} \quad (16)$$

problem (11)–(13) is equivalent to problem (1)–(6) as far as the condition $\mathbf{n} \cdot \mathbf{n}_u > 0$, which is valid for sufficiently small t , is satisfied.

We now introduce some function spaces. Let D be a domain in $\mathbf{R}^n$, let T be a positive constant, let D_T be a cylindrical domain $D \times (0, T)$, let l be a nonnegative integer, and let $\alpha, \gamma \in (0, 1)$.

By $C^{l+\alpha}(D)$, we define the space of functions $f(x)$, $x \in D$, with the norm

$$\begin{aligned} |f|_D^{(l+\alpha)} &\equiv \sum_{|m| \leq l} |\partial_x^m f|_D + [f]_D^{(l+\alpha)}, \quad |f|_D \equiv \sup_{x \in D} |f(x)|, \\ [f]_D^{(l+\alpha)} &\equiv \sum_{|m|=l} |\partial_x^m f|_D^{(\alpha)} \equiv \sup_{x, y \in D, x \neq y} \sum_{m=|l|} \frac{|\partial_x^m f(x) - \partial_y^m f(y)|}{|x - y|^\alpha}, \\ |m| &= \sum_{i=1}^n m_i, \quad \partial_x^m = \frac{\partial^{|m|}}{\partial x_1^{m_1} \dots \partial x_n^{m_n}}, \end{aligned} \quad (17)$$

for a multi-index $m = (m_i)$ ($m_i \geq 0, i = 1, \dots, n$).

By $C^{l+\alpha, ((l+\alpha)/2)}(D_T)$ we denote an anisotropic Hölder space of functions whose norm is defined by

$$|f|_{D_T}^{(l+\alpha, ((l+\alpha)/2))} \equiv \sum_{2r+|m|=0}^l |\partial_t^r \partial_x^m f|_{D_T} + [f]_{D_T}^{(l+\alpha, ((l+\alpha)/2))}, \quad (18)$$

where

$$\begin{aligned} |f|_{D_T} &\equiv \sup_{(x,t) \in D_T} |f(x, t)|, \\ [f]_{D_T}^{(l+\alpha, ((l+\alpha)/2))} &\equiv \sum_{2r+|m|=l-1}^l [\partial_t^r \partial_x^m f]_{D_T}^{(0, ((l+\alpha)-(2r+|m|)/2))} \\ &\quad + \sum_{2r+|m|=l} [\partial_t^r \partial_x^m f]_{D_T}^{(\alpha, 0)}. \end{aligned} \quad (19)$$

Here,

$$\begin{aligned} [f]_{D_T}^{(0, (\alpha/2))} &\equiv \sup_{(x,t), (x',t') \in D_T, t \neq t'} \frac{|f(x, t) - f(x', t')|}{|t - t'|^{(\alpha/2)}}, \\ [f]_{D_T}^{(\alpha, 0)} &\equiv \sup_{(x,t), (x',t) \in D_T, x \neq x'} \frac{|f(x, t) - f(x', t)|}{|x - x'|^\alpha}. \end{aligned} \quad (20)$$

Finally, we introduce the function space $C^{1+\alpha, \gamma}(D_T)$ equipped with the norm

$$\|f\|_{D_T}^{(1+\alpha, \gamma)} \equiv |f|_{D_T} + |\nabla f|_{D_T}^{(\alpha, (\alpha/2))} + |f|_{D_T}^{(1+\alpha, \gamma)}, \quad (21)$$

where

$$|f|_{D_T}^{(1+\alpha, \gamma)} \equiv \sup_{\tau, t \in (0, T), \tau \neq t} \frac{|f(\cdot, t) - f(\cdot, \tau)|_D^{(\gamma)}}{|t - \tau|^{((1+\alpha-\gamma)/2)}}. \quad (22)$$

Now, let us state our main result.

Theorem 1. Let α, γ be constants satisfying $0 < \alpha, \gamma < 1$. Assume that

$$\mathbf{v}_0 \in C^{2+\alpha}(\bar{\Omega}), \quad \rho_0^s \in C^{2+\alpha}(\Gamma), \quad \Gamma \in C^{3+\alpha}. \quad (23)$$

Assume that there exist positive constants Δ_1 and Δ_2 such that $\bar{\rho} - \rho_0^s \geq \Delta_1 > 0$ and $\rho_0^s \geq \Delta_2 > 0$ on Γ . In addition, assume that the following compatibility conditions are satisfied:

$$\nabla \cdot \mathbf{v}_0 = \mathbf{0}, \quad (\nu \Pi D(\mathbf{v}_0) \mathbf{n} + \gamma \nabla_{\Gamma} \rho_0^s) \Big|_{\Gamma} = \mathbf{0}, \quad (24)$$

where ∇_{Γ} is the operator corresponding to ∇_{Γ_t} with $t = 0$; namely, ∇_{Γ} is given by the formula in (14) with $X_u(s) = \xi(s)$.

Then, for a positive constant T , problem (11)–(13) has a unique solution $(\mathbf{u}, q, r^s)$ with the following smoothness:

$$\begin{aligned} \mathbf{u} &\in C^{2+\alpha, 1+(\alpha/2)}(\Omega_{0T}), \\ q &\in C^{1+\alpha, \gamma}(\Omega_{0T}) \cap C^{1+\alpha, ((1+\alpha)/2)}(\Gamma_{0T}), \\ r^s &\in C^{2+\alpha, 1+(\alpha/2)}(\Gamma_{0T}). \end{aligned} \quad (25)$$

3. Proof of the Main Result

In this section, we will prove Theorem 1.

We begin with preparing estimates of solutions to some linear problems. For the following problem:

$$\begin{aligned} \frac{\partial \mathbf{u}}{\partial t} - \nu \nabla_w^2 \mathbf{u} + \nabla_w q &= \mathbf{F}_1, \quad \nabla_w \cdot \mathbf{u} = F_2 \quad \text{in } \Omega_{0T}, \\ \nu \Pi \Pi_w \mathbf{D}_w(\mathbf{u}) \mathbf{n}_w &= \mathbf{F}_3, \\ \mathbf{n} \cdot \mathbf{T}_w(\mathbf{u}, q) \mathbf{n}_w - \bar{\Theta} \mathbf{n} \cdot \nabla_{\bar{\Gamma}_t}^2 \int_0^t \mathbf{u} d\tau &= b + \int_0^t B d\tau \quad \text{on } \Gamma_{0T}, \\ \mathbf{u}|_{t=0} &= \mathbf{v}_0 \quad \text{on } \bar{\Omega}, \end{aligned} \quad (26)$$

the following result is given in [6]. In (26), ∇_w , Π_w , $\mathbf{T}_w(\mathbf{u}, q)$ ($= \nu \mathbf{D}_w(\mathbf{u}) - qI$), $\mathbf{n}_w$ are defined for a given vector $\mathbf{w}$ in the same manner as ∇_u , Π_u , $\mathbf{T}_u(\mathbf{u}, q)$, $\mathbf{n}_u$ are defined, and $\nabla_{\bar{\Gamma}_t}$ is defined by (14) with $X_u = X_w$.

Theorem 2. Let $T > 0$, and let α, γ be positive constants satisfying $0 < \alpha, \gamma < 1$. Assume that

$$\begin{aligned} \Gamma &\in C^{2+\alpha}, \quad \mathbf{v}_0 \in C^{2+\alpha}(\bar{\Omega}), \\ \mathbf{F}_1 &\in C^{\alpha, (\alpha/2)}(\Omega_{0T}), \quad F_2 \in C^{1+\alpha, ((1+\alpha)/2)}(\Omega_{0T}), \\ \mathbf{F}_3 &\in C^{1+\alpha, ((1+\alpha)/2)}(\Gamma_{0T}), \quad b \in C^{1+\alpha, ((1+\alpha)/2)}(\Gamma_{0T}), \\ B &\in C^{\alpha, (\alpha/2)}(\Gamma_{0T}), \quad \bar{\Theta} \in C^\alpha(\Gamma). \end{aligned} \quad (27)$$

Assume that there exists a positive constant Δ_1 such that $\bar{\Theta} \geq \Delta_1 > 0$ on Γ . Assume that the following compatibility conditions are satisfied:

$$\nabla \cdot \mathbf{v}_0 = F_2(\xi, 0), \quad \nu \Pi \mathbf{D}(\mathbf{v}_0) \mathbf{n}|_\Gamma = \mathbf{F}_3(\xi, 0). \quad (28)$$

Assume that there exist functions $\mathbf{h} \in C^{\alpha, (\alpha/2)}(\Omega_{0T})$, $\mathbf{H}_k$, $k = 1, 2, 3$, with a finite norm $|\mathbf{H}_k|_{\Omega_{0T}}^{(1+\alpha, \gamma)}$ satisfying the relation

$$\frac{\partial F_2}{\partial t} - \nabla_w \cdot \mathbf{F}_1 = \nabla \cdot \mathbf{h}, \quad \mathbf{h} = \sum_{k=1}^3 \partial_{\xi_k} \mathbf{H}_k, \quad (29)$$

in the sense of distribution. Furthermore, assume that $\mathbf{w} \in C^{2+\alpha, 1+(\alpha/2)}(\Omega_{0T})$ satisfies the inequality

$$(T + T^{1/2}) |\mathbf{w}|_{\Omega_{0T}}^{(2+\alpha, 1+(\alpha/2))} + T^{((1-\alpha+\gamma)/2)} |\partial_\xi \mathbf{w}|_{\Omega_{0T}} \leq \delta, \quad (30)$$

for a sufficiently small positive constant δ .

Then problem (26) has a unique solution $(\mathbf{u}, q)$ satisfying the following inequality:

$$\begin{aligned} |\mathbf{u}|_{\Omega_{0T}}^{(2+\alpha, 1+(\alpha/2))} + \|q\|_{\Omega_{0T}}^{(1+\alpha, \gamma)} + |q|_{\Gamma_{0T}}^{(1+\alpha, ((1+\alpha)/2))} \\ \leq \bar{C}_1(T) \left\{ |\mathbf{F}_1|_{\Omega_{0T}}^{(\alpha, (\alpha/2))} + |F_2|_{\Omega_{0T}}^{(1+\alpha, ((1+\alpha)/2))} \right. \\ + |\mathbf{F}_3|_{\Gamma_{0T}}^{(1+\alpha, ((1+\alpha)/2))} + |b|_{\Gamma_{0T}}^{(1+\alpha, ((1+\alpha)/2))} \\ + |B|_{\Gamma_{0T}}^{(\alpha, (\alpha/2))} + |\mathbf{v}_0|_{\Omega}^{(2+\alpha)} + |\mathbf{h}|_{\Omega_{0T}}^{(\alpha, (\alpha/2))} \\ \left. + \sum_{k=1}^3 |\mathbf{H}_k|_{\Omega_{0T}}^{(1+\alpha, \gamma)} + P_T(\mathbf{w}) \left(|\mathbf{v}_0|_{\Omega}^{(1)} + |b(\cdot, 0)|_{\Gamma} \right) \right\}, \end{aligned} \quad (31)$$

where $P_T(\mathbf{w}) = T^{((1-\alpha)/2)} |\mathbf{w}|_{\Omega_{0T}}^{(1,0)} + |\partial_\xi \mathbf{w}|_{\Omega_{0T}}^{(\alpha, (\alpha/2))} + |\partial_\xi \mathbf{w}|_{\Omega_{0T}}^{(0, ((1+\alpha-\gamma)/2))}$ and $\bar{C}_1(T)$ is a nondecreasing function of T .

For the following problem:

$$\begin{aligned} \frac{\partial r^s}{\partial t} - \chi \gamma \rho_0^s \nabla_{\bar{\Gamma}_t}^2 r^s &= G \quad \text{on } \Gamma_{0T}, \\ r^s|_{t=0} &= \rho_0^s \quad \text{on } \Gamma, \end{aligned} \quad (32)$$

we have the following theorem. The assertion of the theorem immediately follows from the Hölder estimates for linear parabolic equations (e.g., see [7]).

Theorem 3. Let $T > 0$, and let α be a positive constant satisfying $0 < \alpha < 1$. Assume that

$$\Gamma \in C^{2+\alpha}, \quad \rho_0^s \in C^{2+\alpha}(\Gamma), \quad G \in C^{\alpha, (\alpha/2)}(\Gamma_{0T}). \quad (33)$$

Assume that there exists a positive constant Δ_2 such that $\rho_0^s \geq \Delta_2 > 0$ on Γ . Further assume the same assumptions for $\mathbf{w}$ stated in Theorem 2.

Then, problem (32) has a unique solution r^s satisfying the following inequality:

$$|r^s|_{\Gamma_{0T}}^{(2+\alpha, 1+(\alpha/2))} \leq \bar{C}_2(T) \left(|G|_{\Gamma_{0T}}^{(\alpha, (\alpha/2))} + |\rho_0^s|_{\Gamma}^{(2+\alpha)} \right), \quad (34)$$

where $\bar{C}_2(T)$ is a nondecreasing function of T .

Combining the above results, we can easily obtain Theorem 4 given below for the following problem:

$$\begin{aligned}
\frac{\partial \mathbf{u}}{\partial t} - \nu \nabla_w^2 \mathbf{u} + \nabla_w q &= \mathbf{F}_1, \quad \nabla_w \cdot \mathbf{u} = F_2 \quad \text{in } \Omega_{0T}, \\
\nu \Pi \Pi_w \mathbf{D}_w(\mathbf{u}) \mathbf{n}_w + \gamma \Pi \nabla_{\tilde{\Gamma}_t} r^s &= \mathbf{F}_3, \\
\mathbf{n} \cdot \mathbf{T}_w(\mathbf{u}, q) \mathbf{n}_w - \bar{\Theta} \mathbf{n} \cdot \nabla_{\tilde{\Gamma}_t}^2 \int_0^t \mathbf{u} d\tau + \gamma \mathbf{n} \cdot \nabla_{\tilde{\Gamma}_t} r^s & \\
= b + \int_0^t B d\tau \quad \text{on } \Gamma_{0T}, & \quad (35) \\
\mathbf{u}|_{t=0} = \mathbf{v}_0 \quad \text{on } \bar{\Omega}, & \\
\frac{\partial r^s}{\partial t} - \chi \gamma \rho_0^s \nabla_{\tilde{\Gamma}_t}^2 r^s &= G \quad \text{on } \Gamma_{0T}, \\
r^s|_{t=0} = \rho_0^s \quad \text{on } \Gamma. &
\end{aligned}$$

The estimate given in the theorem will be essentially used in the later argument to prove Theorem 1.

Theorem 4. Under the same assumptions given in Theorem 2 where only compatibility condition is replaced by

$$\nabla \cdot \mathbf{v}_0 = F_2(\xi, 0), \quad (\nu \Pi \mathbf{D}(\mathbf{v}_0) \mathbf{n} + \gamma \Pi \nabla_{\Gamma} \rho_0^s)|_{\Gamma} = \mathbf{F}_3(\xi, 0), \quad (36)$$

and Theorem 3, problem (35) has a unique solution $(\mathbf{u}, q, r^s)$ satisfying the following inequality:

$$\begin{aligned}
& |\mathbf{u}|_{\Omega_{0T}}^{(2+\alpha, 1+(\alpha/2))} + \|q\|_{\Omega_{0T}}^{(1+\alpha, \gamma)} + |q|_{\Gamma_{0T}}^{(1+\alpha, ((1+\alpha)/2))} + |r^s|_{\Gamma_{0T}}^{(2+\alpha, 1+(\alpha/2))} \\
& \leq \bar{C}_3(T) \left\{ |\mathbf{F}_1|_{\Omega_{0T}}^{(\alpha, (\alpha/2))} + |F_2|_{\Omega_{0T}}^{(1+\alpha, ((1+\alpha)/2))} \right. \\
& \quad + |\mathbf{F}_3|_{\Gamma_{0T}}^{(1+\alpha, ((1+\alpha)/2))} + |b|_{\Gamma_{0T}}^{(1+\alpha, ((1+\alpha)/2))} \\
& \quad + |B|_{\Gamma_{0T}}^{(\alpha, (\alpha/2))} + |\mathbf{h}|_{\Omega_{0T}}^{(\alpha, (\alpha/2))} + \sum_{k=1}^3 |\mathbf{H}_k|_{\Omega_{0T}}^{(1+\alpha, \gamma)} \\
& \quad + |\mathbf{v}_0|_{\Omega}^{(2+\alpha)} + |G|_{\Gamma_{0T}}^{(\alpha, (\alpha/2))} + |\rho_0^s|_{\Gamma}^{(2+\alpha)} \\
& \quad \left. + P_T(\mathbf{w}) \left(|\mathbf{v}_0|_{\Omega}^{(1)} + |b(\cdot, 0)|_{\Gamma} \right) \right\}, \quad (37)
\end{aligned}$$

where $\bar{C}_3(T)$ is a nondecreasing function of T .

In addition, we prepare estimates for $\mathcal{J}_u^*$, which are used later.

Lemma 5. Let $\mathcal{J}_u$ and $\mathcal{J}_{u'}$ be the Jacobian matrices of the mappings X_u and $X_{u'}$, respectively. Let us assume that $\mathbf{u}$ and $\mathbf{u}'$ satisfy condition (30) for sufficiently small $\delta > 0$. Then, the following inequalities hold:

$$|\mathcal{J}_u^*|_{\Omega_{0T}}^{(1+\alpha, ((1+\alpha)/2))}, |\mathcal{J}_{u'}^*|_{\Omega_{0T}}^{(1+\alpha, \gamma)} \leq C, \quad (38)$$

where C is a positive constant independent of δ , and

$$\begin{aligned}
& |\mathcal{J}_u^* - \mathcal{J}_{u'}^*|_{\Omega_{0T}}^{(1+\alpha, ((1+\alpha)/2))}, |\mathcal{J}_u^* - \mathcal{J}_{u'}^*|_{\Omega_{0T}}^{(1+\alpha, \gamma)} \\
& \leq \epsilon |\mathbf{u} - \mathbf{u}'|_{\Omega_{0T}}^{(2+\alpha, 1+(\alpha/2))} + C(\epsilon) \int_0^T |\mathbf{u} - \mathbf{u}'|_{\Omega_{0T}}^{(2+\alpha, 1+(\alpha/2))} d\tau, \quad (39)
\end{aligned}$$

for arbitrary $0 < \epsilon < 1$, where $C(\epsilon)$ is a positive constant depending only on ϵ .

Proof. In the following proof, c_1 , c_2 , and c_3 are positive constants independent of δ and ϵ . Let a_{ij} be the (i, j) -component of $\mathcal{J}_u$.

Then, we have

$$\delta_{ij} - \left| \int_0^t \partial_{\xi_j} u_i d\tau \right| \leq a_{ij} \leq \delta_{ij} + \left| \int_0^t \partial_{\xi_j} u_i d\tau \right|, \quad (40)$$

where δ_{ij} denotes Kronecker's delta. Then, using the inequality

$$\left| \int_0^t \partial_{\xi_j} u_i d\tau \right|_{\Omega_{0T}} \leq T |\mathbf{u}|_{\Omega_{0T}}^{(1,0)} \leq \delta, \quad (41)$$

from (40), we have

$$\delta_{ij} - \delta \leq |a_{ij}|_{\Omega_{0T}} \leq \delta_{ij} + \delta. \quad (42)$$

This inequality implies that $\det \mathcal{J}_u > 0$ holds for sufficiently small $\delta > 0$.

Now, let a'_{ij} be the (i, j) -components of $\mathcal{J}_{u'}$, and let A_{ij} and A'_{ij} be the cofactors of a_{ij} and a'_{ij} , respectively.

Then from the inequalities

$$|a_{ij}|_{\Omega_{0T}}^{(1+\alpha, ((1+\alpha)/2))}, |a'_{ij}|_{\Omega_{0T}}^{(1+\alpha, ((1+\alpha)/2))} \leq c_1 (1 + \delta), \quad (43)$$

we have

$$|A_{ij}|_{\Omega_{0T}}^{(1+\alpha, ((1+\alpha)/2))}, |A'_{ij}|_{\Omega_{0T}}^{(1+\alpha, \gamma)} \leq c_2. \quad (44)$$

On the other hand, from the inequality

$$\begin{aligned}
& |a_{ij} - a'_{ij}|_{\Omega_{0T}}^{(1+\alpha, ((1+\alpha)/2))} \\
& \leq \epsilon |\mathbf{u} - \mathbf{u}'|_{\Omega_{0T}}^{(2+\alpha, 1+(\alpha/2))} \\
& \quad + c_3 \left(1 + \epsilon^{-((1+\alpha)/(2-\alpha))} \right) \int_0^T |\mathbf{u} - \mathbf{u}'|_{\Omega_{0T}}^{(2+\alpha, 1+(\alpha/2))} d\tau, \quad (45)
\end{aligned}$$

which are obtained with the aid of the following inequality which holds for arbitrary $0 < \epsilon < 1$:

$$\begin{aligned}
& \left| \int_0^t f(\xi, \tau) d\tau \right|_{\Omega_{0T}}^{(1+\alpha, ((1+\alpha)/2))} \\
& \leq \int_0^T |f|_{\Omega_{0\tau}}^{(1+\alpha, 0)} d\tau \\
& + \sup_{|t'-t''| < \epsilon^{(2/(1-\alpha))}} \left(|t' - t''|^{-((1+\alpha)/2)} \int_{t''}^{t'} |f(\xi, \tau)|_{\Omega} d\tau \right. \\
& \quad \left. + |t' - t''|^{-(\alpha/2)} \int_{t''}^{t'} |\partial_{\xi} f(\xi, \tau)|_{\Omega} d\tau \right) \\
& + \sup_{\epsilon^{(2/(1-\alpha))} < |t'-t''| \leq T} \left(|t' - t''|^{-((1+\alpha)/2)} \int_{t''}^{t'} |f(\xi, \tau)|_{\Omega} d\tau \right. \\
& \quad \left. + |t' - t''|^{-(\alpha/2)} \int_{t''}^{t'} |\partial_{\xi} f(\xi, \tau)|_{\Omega} d\tau \right) \\
& \leq \epsilon |f|_{\Omega_{0T}}^{(1+\alpha, ((1+\alpha)/2))} \\
& + c_3 \left(1 + \epsilon^{-((1+\alpha)/(1-\alpha))} \right) \int_0^T |f|_{\Omega_{0\tau}}^{(1+\alpha, ((1+\alpha)/2))} d\tau, \tag{46}
\end{aligned}$$

we have

$$\begin{aligned}
& |A_{ij} - A'_{ij}|_{\Omega_{0T}}^{(1+\alpha, ((1+\alpha)/2))}, |A_{ij} - A'_{ij}|_{\Omega_{0T}}^{(1+\alpha, \gamma)} \\
& \leq \epsilon |\mathbf{u} - \mathbf{u}'|_{\Omega_{0T}}^{(2+\alpha, 1+(\alpha/2))} + C_1(\epsilon) \int_0^T |\mathbf{u} - \mathbf{u}'|_{\Omega_{0\tau}}^{(2+\alpha, 1+(\alpha/2))} d\tau, \tag{47}
\end{aligned}$$

where $C_1(\epsilon)$ is a positive constant depending only on ϵ . From (44) and (47), estimates (38) and (39) immediately follow. Thus, the proof is completed. $\square$

Now, let us prove Theorem 1 by the method of successive approximations. We take $(\mathbf{u}_0, q_0, r_0^s) = (\mathbf{0}, 0, 0)$, and, for the known n th approximation, we define the $(n+1)$ th approximation by the solutions of the following problem:

$$\begin{aligned}
& \frac{\partial \mathbf{u}_{n+1}}{\partial t} - \gamma \nabla_{u_n}^2 \mathbf{u}_{n+1} + \nabla_{u_n} q_{n+1} = \mathbf{0}, \\
& \nabla_{u_n} \cdot \mathbf{u}_{n+1} = 0 \quad \text{in } \Omega_{0T}, \\
& \gamma \Pi \Pi_{u_n} \mathbf{D}_{u_n}(\mathbf{u}_{n+1}) \mathbf{n}_{u_n} + \gamma \Pi \nabla_{\Gamma_{n,t}} r_{n+1}^s = \mathbf{0}, \\
& \mathbf{n} \cdot \mathbf{T}_{u_n}(\mathbf{u}_{n+1}, q_{n+1}) \mathbf{n}_{u_n} - \bar{\Theta} \mathbf{n} \cdot \nabla_{\Gamma_{n,t}}^2 \int_0^t \mathbf{u}_{n+1} d\tau \\
& + \gamma \mathbf{n} \cdot \nabla_{\Gamma_{n,t}} r_{n+1}^s \\
& = b(\mathbf{u}_n, r_n^s) + \int_0^t B(\mathbf{u}_n, r_n^s) d\tau \quad \text{on } \Gamma_{0T},
\end{aligned}$$

$$\mathbf{u}_{n+1}|_{t=0} = \mathbf{v}_0 \quad \text{on } \bar{\Omega},$$

$$\frac{\partial r_{n+1}^s}{\partial t} - \chi \gamma \rho_0^s \nabla_{\Gamma_{n,t}}^2 r_{n+1}^s = G(r_n^s, \mathbf{u}_n) \quad \text{on } \Gamma_{0T},$$

$$r_{n+1}^s|_{t=0} = \rho_0^s \quad \text{on } \Gamma,$$

(48)

where

$$\begin{aligned}
b(\mathbf{u}_n, r_n^s) &= \theta_n \left(H_0 + \mathbf{n} \cdot \int_0^t (\nabla_{\Gamma_{n,\tau}}^2)_{\tau} \xi d\tau \right), \\
H_0 &= \mathbf{n} \cdot \nabla_{\Gamma}^2 \xi \\
B(\mathbf{u}_n, r_n^s) &= \left\{ \frac{\partial}{\partial \tau} (\theta_n - \bar{\Theta}) \right\} \mathbf{n} \cdot \nabla_{\Gamma_{n,\tau}}^2 \int_0^{\tau} \mathbf{u}_n(\xi, s) ds \\
&+ (\theta_n - \bar{\Theta}) \mathbf{n} \cdot (\nabla_{\Gamma_{n,\tau}}^2)_{\tau} \int_0^{\tau} \mathbf{u}_n(\xi, s) ds \tag{49} \\
&+ (\theta_n - \bar{\Theta}) \mathbf{n} \cdot \nabla_{\Gamma_{n,\tau}}^2 \mathbf{u}_n, \\
\theta_n &= \gamma (\bar{\rho} - r_n^s), \quad \bar{\Theta} = \gamma (\bar{\rho} - \rho_0^s), \\
G(\mathbf{u}_n, r_n^s) &\equiv -r_n^s \nabla_{\Gamma_{n,t}} \cdot \mathbf{u}_n \\
&+ \chi \gamma \{ (r_n^s - \rho_0^s) \nabla_{\Gamma_{n,t}}^2 r_n^s + \nabla_{\Gamma_{n,t}} r_n^s \cdot \nabla_{\Gamma_{n,t}} r_n^s \}.
\end{aligned}$$

In the above formulas, $\nabla_{\Gamma_{n,t}}$ is the operator corresponding to ∇_{Γ_t} with $X_u = X_{u_n}$, and $(\nabla_{\Gamma_{n,\tau}}^2)_{\tau}$ denotes the operator obtained by differentiating the coefficients of $\nabla_{\Gamma_{n,\tau}}^2$ with respect to τ .

Now, let us verify that all terms of the sequence $\{(\mathbf{u}_n, q_n, r_n^s)\}$ are defined on some time interval independent of n . We begin with the following lemma.

Lemma 6. *Let T_n be a constant satisfying $0 < T_n \leq 1$. Then there exist positive constants δ and β such that if $\mathbf{u}_n$ and r_n^s satisfy the following conditions:*

$$\begin{aligned}
& (T_n + T_n^{1/2}) |\mathbf{u}_n|_{\Omega_{0T_n}}^{(2+\alpha, 1+(\alpha/2))} + T_n^{((1-\alpha+\gamma)/2)} |\partial_{\xi} \mathbf{u}_n|_{\Omega_{0T_n}} \leq \delta, \\
& (T_n + T_n^{\beta}) \left(|\mathbf{u}_n|_{\Omega_{0T_n}}^{(2+\alpha, 1+(\alpha/2))} + |r_n^s|_{\Gamma_{0T_n}}^{(2+\alpha, 1+(\alpha/2))} \right) \leq \delta, \tag{50}
\end{aligned}$$

then the following inequality holds for a positive constant $\bar{C}$ independent of $\mathbf{u}_n, r_n^s$ and T_n :

$$\begin{aligned}
& |b(\mathbf{u}_n, r_n^s)|_{\Gamma_{0T_n}}^{(1+\alpha, ((1+\alpha)/2))} + |B(\mathbf{u}_n, r_n^s)|_{\Gamma_{0T_n}}^{(\alpha, (\alpha/2))} \\
& + |G(\mathbf{u}_n, r_n^s)|_{\Gamma_{0T_n}}^{(\alpha, (\alpha/2))} + P_{T_n}(\mathbf{u}_n) \leq \bar{C}. \tag{51}
\end{aligned}$$

Proof. In the proof, $c_1, \dots, c_9$ are positive constants independent of $\mathbf{u}_n, r_n^s$, and T_n .

Choosing $T_n^{((1-\alpha)/2\alpha)}$ as ϵ in the following interpolation inequality:

$$\begin{aligned} & |\theta_n - (\theta_n|_{t=0})|_{\Gamma_{0T_n}}^{(1+\alpha, (1+\alpha)/2)} \\ & \leq \epsilon |r_n^s - \rho_0^s|_{\Gamma_{0T_n}}^{(2,1)} + c_1 \epsilon^{-(\alpha/(1-\alpha))} |r_n^s - \rho_0^s|_{\Gamma_{0T_n}} \\ & \leq \epsilon |r_n^s - \rho_0^s|_{\Gamma_{0T_n}}^{(2,1)} + c_1 \epsilon^{-(\alpha/(1-\alpha))} \int_0^{T_n} |\partial_\tau (r_n^s - \rho_0^s)|_{\Gamma_{0\tau}} d\tau, \end{aligned} \quad (52)$$

we have the following estimate:

$$\begin{aligned} & |\theta_n|_{\Gamma_{0T_n}}^{(1+\alpha, (1+\alpha)/2)} \\ & \leq c_2 \left(|\rho_0^s|_{\Gamma}^{(1+\alpha)} + |\theta_n - (\theta_n|_{t=0})|_{\Gamma_{0T_n}}^{(1+\alpha, (1+\alpha)/2)} \right) \\ & \leq c_3 \left\{ |\rho_0^s|_{\Gamma}^{(1+\alpha)} + \left(T_n^{((1-\alpha)/2\alpha)} + T_n^{(1/2)} \right) |r_n^s - \rho_0^s|_{\Gamma_{0T_n}}^{(2,1)} \right\} \\ & \leq c_4 (1 + \delta). \end{aligned} \quad (53)$$

With the aid of the above estimate, we can easily obtain the desired estimate for $b(\mathbf{u}_n, r_n^s)$.

$B(\mathbf{u}_n, r_n^s)$ is estimated as follows. With the aid of the inequality

$$\begin{aligned} & \left| \int_0^t \partial_\xi^2 f(\xi, \tau) d\tau \right|_{\Gamma_{0T}}^{(\alpha, (\alpha/2))} \\ & \leq c_5 \left(T + T^{1-(\alpha/2)} \right) |f|_{\Gamma_{0T}}^{(2+\alpha, 1+(\alpha/2))}, \end{aligned} \quad (54)$$

we have

$$\begin{aligned} & \left| \left\{ \frac{\partial}{\partial t} (\theta_n - \bar{\theta}) \right\} \mathbf{n} \cdot \nabla_{\Gamma_{n,t}}^2 \int_0^t \mathbf{u}_n(\xi, \tau) d\tau \right. \\ & \quad \left. + (\theta_n - \bar{\theta}) \mathbf{n} \cdot (\nabla_{\Gamma_{n,t}}^2) \int_0^t \mathbf{u}_n(\xi, \tau) d\tau \right|_{\Gamma_{0T_n}}^{(\alpha, (\alpha/2))} \\ & \leq c_6 \left(T_n + T_n^{1-(\alpha/2)} \right) |r_n^s - \rho_0^s|_{\Gamma_{0T_n}}^{(2+\alpha, 1+(\alpha/2))} |\mathbf{u}_n|_{\Gamma_{0T_n}}^{(2+\alpha, 1+(\alpha/2))} \\ & \leq c_7 (1 + \delta^2). \end{aligned} \quad (55)$$

On the other hand, with the aid of

$$\begin{aligned} & |\theta_n - \bar{\theta}|_{\Gamma_{0T_n}}^{(\alpha, (\alpha/2))} \leq \int_0^{T_n} |\partial_\tau (\theta_n - \bar{\theta})|_{\Gamma_{0\tau}}^{(\alpha, (\alpha/2))} d\tau \\ & \leq T_n |r_n^s - \rho_0^s|_{\Gamma_{0T_n}}^{(2+\alpha, 1+(\alpha/2))}, \end{aligned} \quad (56)$$

we have

$$\begin{aligned} & \left| (\theta_n - \bar{\theta}) \mathbf{n} \cdot \nabla_{\Gamma_{n,t}}^2 \mathbf{u}_n \right|_{\Gamma_{0T_n}}^{(\alpha, (\alpha/2))} \\ & \leq c_8 T_n |r_n^s - \rho_0^s|_{\Gamma_{0T_n}}^{(2+\alpha, 1+(\alpha/2))} |\mathbf{u}_n|_{\Gamma_{0T_n}}^{(2+\alpha, 1+(\alpha/2))} \\ & \leq c_9 (1 + \delta^2). \end{aligned} \quad (57)$$

From (55) and (57), we have the desired estimate for $B(\mathbf{u}_n, r_n^s)$. $G(\mathbf{u}_n, r_n^s)$ and $P_{T_n}(\mathbf{u}_n)$ are estimated in a similar manner. Thus, we have proved the lemma. $\square$

From this lemma, if $\mathbf{u}_n$ and r_n^s satisfy conditions (50), by applying Theorem 4 to problem (3) we have the following estimate of $\mathbf{u}_{n+1}$ and r_{n+1}^s :

$$|\mathbf{u}_{n+1}|_{\Omega_{0T_n}}^{(2+\alpha, 1+(\alpha/2))} + |r_{n+1}^s|_{\Gamma_{0T_n}}^{(2+\alpha, 1+(\alpha/2))} \leq \bar{C}_3(1) \bar{C}, \quad (58)$$

where $\bar{C}_3(\cdot)$ is the function given in Theorem 4.

Now, let us take T satisfying the following conditions:

$$0 < T \leq 1, \quad \bar{C}_3(1) \bar{C} (T + T^\beta) \leq \delta. \quad (59)$$

Here β is assumed to be chosen, so that $\beta < 1/2$ and $\beta < (1 - \alpha + \gamma)/2$. Since $(\mathbf{u}_0, r_0^s) = (\mathbf{0}, 0)$, the zeroth approximation $(\mathbf{u}_0, r_0^s)$ obviously satisfies conditions (50) for the above T . Hence, from (58), $(\mathbf{u}_1, r_1^s)$ satisfies

$$|\mathbf{u}_1|_{\Omega_{0T}}^{(2+\alpha, 1+(\alpha/2))} + |r_1^s|_{\Gamma_{0T}}^{(2+\alpha, 1+(\alpha/2))} \leq \bar{C}_3(1) \bar{C}. \quad (60)$$

From (59), this inequality indicates that $(\mathbf{u}_1, r_1^s)$ satisfies conditions (50), and hence we can obtain the same estimate as (60) for $(\mathbf{u}_2, r_2^s)$. Thus, repeating this argument, we can construct a sequence $\{(\mathbf{u}_n, q_n, r_n^s)\}$ such that each term is defined on $(0, T)$.

Let us proceed to the proof of the convergence of the sequence $\{(\mathbf{u}_n, q_n, r_n^s)\}$. In the following argument, $C_1, \dots, C_{10}$ denote positive constants independent of n and $C(\epsilon)$ represents various positive constants depending only on ϵ .

Let us set

$$\begin{aligned} U^{(n+1)} & \equiv \mathbf{u}_{n+1} - \mathbf{u}_n, \\ Q^{(n+1)} & \equiv q_{n+1} - q_n, \quad R^{(n+1)} \equiv r_{n+1}^s - r_n^s. \end{aligned} \quad (61)$$

Subtracting (3) with index n from that with index $n + 1$, we have

$$\begin{aligned} & \frac{\partial U^{(n+1)}}{\partial t} - \gamma \nabla_{u_n}^2 U^{(n+1)} + \nabla_{u_n} Q^{(n+1)} = \mathcal{F}_1^{(n)}, \\ & \nabla_{u_n} \cdot U^{(n+1)} = \mathcal{F}_2^{(n)} \quad \text{in } \Omega_{0T}, \\ & \gamma \Pi \Pi_{u_n} \mathbf{D}_{u_n} (U^{(n+1)}) \mathbf{n}_{u_n} + \gamma \Pi \nabla_{\Gamma_{n,t}}^2 R^{(n+1)} = \mathcal{F}_3^{(n)}, \\ & \mathbf{n} \cdot \mathbf{T}_{u_n} (U^{(n+1)}, Q^{(n+1)}) \mathbf{n}_{u_n} - \bar{\Theta} \mathbf{n} \cdot \nabla_{\Gamma_{n,t}}^2 \int_0^t U^{(n+1)} d\tau \\ & \quad + \gamma \mathbf{n} \cdot \nabla_{\Gamma_{n,t}} R^{(n+1)} \\ & = b^{(n)} + \int_0^t \mathcal{B}^{(n)} d\tau \quad \text{on } \Gamma_{0T}, \end{aligned}$$

$$\begin{aligned}
U^{(n+1)}|_{t=0} &= \mathbf{0} \quad \text{on } \bar{\Omega}, \\
\frac{\partial R^{(n+1)}}{\partial t} - \chi \gamma \rho_0^s \nabla_{\Gamma_{nt}}^2 R^{(n+1)} &= \mathcal{G}^{(n)} \quad \text{in } \Gamma_{0T}, \\
R^{(n+1)}|_{t=0} &= 0 \quad \text{on } \Gamma,
\end{aligned} \tag{62}$$

where

$$\begin{aligned}
\mathcal{F}_1^{(n)} &\equiv \nu (\nabla_{u_n}^2 - \nabla_{u_{n-1}}^2) \mathbf{u}_n - (\nabla_{u_n} - \nabla_{u_{n-1}}) q_n, \\
\mathcal{F}_2^{(n)} &\equiv -(\nabla_{u_n} - \nabla_{u_{n-1}}) \cdot \mathbf{u}_n, \\
\mathcal{F}_3^{(n)} &\equiv -\nu \Pi \{ \Pi_{u_n} \mathbf{D}_{u_n}(\mathbf{u}_n) \mathbf{n}_{u_n} - \Pi_{u_{n-1}} \mathbf{D}_{u_{n-1}}(\mathbf{u}_n) \mathbf{n}_{u_{n-1}} \} \\
&\quad - \gamma \Pi (\nabla_{\Gamma_{nt}} - \nabla_{\Gamma_{n-1,t}}) r_n^s, \\
b^{(n)} &\equiv -\mathbf{n} \cdot \{ \mathbf{T}_{u_n}(\mathbf{u}_n, q_n) \mathbf{n}_{u_n} - \mathbf{T}_{u_{n-1}}(\mathbf{u}_n, q_n) \mathbf{n}_{u_{n-1}} \} \\
&\quad - \gamma \mathbf{n} \cdot (\nabla_{\Gamma_{nt}} - \nabla_{\Gamma_{n-1,t}}) r_n^s + b(\mathbf{u}_n, r_n^s) - b(\mathbf{u}_{n-1}, r_{n-1}^s), \\
\mathcal{B}^{(n)} &\equiv \bar{\Theta} \mathbf{n} \cdot (\nabla_{\Gamma_{n,\tau}}^2 - \nabla_{\Gamma_{n-1,\tau}}^2) \int_0^\tau \mathbf{u}_n(\xi, s) ds \\
&\quad + \bar{\Theta} \mathbf{n} \cdot (\nabla_{\Gamma_{n,\tau}}^2 - \nabla_{\Gamma_{n-1,\tau}}^2) \mathbf{u}_n + B(\mathbf{u}_n, r_n^s) - B(\mathbf{u}_{n-1}, r_{n-1}^s), \\
\mathcal{G}^{(n)} &\equiv \chi \gamma \rho_0^s (\nabla_{\Gamma_{nt}}^2 - \nabla_{\Gamma_{n-1,t}}^2) r_n^s + G(\mathbf{u}_n, r_n^s) - G(\mathbf{u}_{n-1}, r_{n-1}^s).
\end{aligned} \tag{63}$$

Now, noting that the relations $\sum_{j=1}^3 \partial_{\xi_j} A_{ij} = 0$ hold for the cofactors A_{ij} of the Jacobian matrix of any transformation from ξ to x , by direct calculations, we can verify that the following relations hold:

$$\frac{\partial \mathcal{F}_2^{(n)}}{\partial t} - \nabla_{u_n} \cdot \mathcal{F}_1^{(n)} = \nabla \cdot \mathbf{h}^{(n)}, \quad \mathbf{h}^{(n)} = \sum_{k=1}^3 \partial_{\xi_k} \mathbf{H}_k^{(n)}, \tag{64}$$

where

$$\begin{aligned}
\mathbf{H}_k^{(n)} &= -(\mathcal{F}_{u_n}^{-1} - \mathcal{F}_{u_{n-1}}^{-1}) \mathbf{L}_k^{(n)} - \mathcal{F}_{u_n}^{-1} \mathbf{M}_k^{(n)} \\
&\quad + \frac{1}{4\pi} \partial_{\xi_k} \int_{\Omega} \frac{\mathbf{N}_k^{(n)}(\eta, t)}{|\xi - \eta|} d\eta,
\end{aligned} \tag{65}$$

with

$$\begin{aligned}
\mathbf{L}_k^{(n)} &\equiv \nu A_{ik}^{(n-1)} A_{il}^{(n-1)} \partial_{\xi_l} \mathbf{u}_n - \mathcal{F}_{u_{n-1}}^* \mathbf{e}_k q_n, \\
\mathbf{M}_k^{(n)} &\equiv \nu (A_{ik}^{(n)} A_{il}^{(n)} - A_{ik}^{(n-1)} A_{il}^{(n-1)}) \partial_{\xi_l} \mathbf{u}_n \\
&\quad - (\mathcal{F}_{u_n}^* - \mathcal{F}_{u_{n-1}}^*) \mathbf{e}_k q_n, \\
\mathbf{N}_k^{(n)} &\equiv \{ \partial_t (\mathcal{F}_{u_n}^{-1} - \mathcal{F}_{u_{n-1}}^{-1}) \} \mathbf{u}_n \\
&\quad - \{ \partial_{\eta_k} (\mathcal{F}_{u_n}^{-1} - \mathcal{F}_{u_{n-1}}^{-1}) \} \mathbf{L}_k^{(n)} - (\partial_{\eta_k} \mathcal{F}_{u_n}^{-1}) \mathbf{M}_k^{(n)}.
\end{aligned} \tag{66}$$

In (66), the Einstein summation convention is used, $A_{ij}^{(n)}$ denotes the (i, j) -component of $\mathcal{F}_n^*$, and $\mathbf{e}_k, k = 1, 2, 3$, denote fundamental unit vectors in $\mathbf{R}^3$.

For the terms in (63), $\mathbf{h}^{(n)}$, and $\mathbf{H}_k^{(n)}$, we have the following estimate for arbitrary $0 < \epsilon < 1$:

$$\begin{aligned}
& \left| \mathcal{F}_1^{(n)} \right|_{\Omega_{0T}}^{(\alpha, (\alpha/2))} + \left| \mathcal{F}_2^{(n)} \right|_{\Omega_{0T}}^{(1+\alpha, ((1+\alpha)/2))} + \left| \mathcal{F}_3^{(n)} \right|_{\Gamma_{0T}}^{(1+\alpha, ((1+\alpha)/2))} \\
& + \left| b^{(n)} \right|_{\Gamma_{0T}}^{(1+\alpha, ((1+\alpha)/2))} + \left| \mathcal{B}^{(n)} \right|_{\Gamma_{0T}}^{(\alpha, (\alpha/2))} + \left| \mathbf{h}^{(n)} \right|_{\Omega_{0T}}^{(\alpha, (\alpha/2))} \\
& + \sum_{k=1}^3 \left| \mathbf{H}_k^{(n)} \right|_{\Omega_{0T}}^{(1+\alpha, \gamma)} + \left| \mathcal{G}^{(n)} \right|_{\Gamma_{0T}}^{(\alpha, (\alpha/2))} \\
& \leq C_1 \left\{ \epsilon \left(\left| U^{(n)} \right|_{\Omega_{0T}}^{(2+\alpha, 1+(\alpha/2))} + \left| R^{(n)} \right|_{\Gamma_{0T}}^{(2+\alpha, 1+(\alpha/2))} \right) \right. \\
& \quad \left. + C(\epsilon) \int_0^T \left(\left| U^{(n)} \right|_{\Omega_{0\tau}}^{(2+\alpha, 1+(\alpha/2))} + \left| R^{(n)} \right|_{\Gamma_{0\tau}}^{(2+\alpha, 1+(\alpha/2))} \right) d\tau \right\}.
\end{aligned} \tag{67}$$

We will derive here the estimate only of $\mathbf{H}_k^{(n)}$ because the other terms can be estimated in a similar and simpler manner. Noting that the following estimates hold for $\mathbf{u}_n$ and q_n :

$$\left| \mathbf{u}_n \right|_{\Omega_{0T}}^{(2+\alpha, 1+(\alpha/2))} + \left| q_n \right|_{\Omega_{0T}}^{(1+\alpha, \gamma)} \leq C_2, \tag{68}$$

and with the aid of estimates (38) and (39), we have

$$\begin{aligned}
& \left| (\mathcal{F}_{u_n}^{-1} - \mathcal{F}_{u_{n-1}}^{-1}) \mathbf{L}_k^{(n)} \right|_{\Omega_{0T}}^{(1+\alpha, \gamma)}, \left| \mathcal{F}_{u_n}^{-1} \mathbf{M}_k^{(n)} \right|_{\Omega_{0T}}^{(1+\alpha, \gamma)}, \left| \mathbf{N}_k^{(n)} \right|_{\Omega_{0T}}^{(0, ((1+\alpha)/2))} \\
& \leq C_3 \left(\epsilon \left| U^{(n)} \right|_{\Omega_{0T}}^{(2+\alpha, 1+(\alpha/2))} + C(\epsilon) \int_0^T \left| U^{(n)} \right|_{\Omega_{0\tau}}^{(2+\alpha, 1+(\alpha/2))} d\tau \right).
\end{aligned} \tag{69}$$

Noting also the following inequality:

$$\left| \partial_{\xi_k} \int_{\Omega} \frac{\mathbf{N}_k^{(n)}(\eta, t)}{|\xi - \eta|} d\eta \right|_{\Omega_{0T}}^{(1+\alpha, \gamma)} \leq C_4 \left| \mathbf{N}_k^{(n)} \right|_{\Omega_{0T}}^{(0, ((1+\alpha)/2))}, \tag{70}$$

from estimate (69) for $\mathbf{N}_k^{(n)}$, we have

$$\begin{aligned}
& \left| \partial_{\xi_k} \int_{\Omega} \frac{\mathbf{N}_k^{(n)}(\eta, t)}{|\xi - \eta|} d\eta \right|_{\Omega_{0T}}^{(1+\alpha, \gamma)} \\
& \leq C_5 \left(\epsilon \left| U^{(n)} \right|_{\Omega_{0T}}^{(2+\alpha, 1+(\alpha/2))} + C(\epsilon) \int_0^T \left| U^{(n)} \right|_{\Omega_{0\tau}}^{(2+\alpha, 1+(\alpha/2))} d\tau \right).
\end{aligned} \tag{71}$$

Thus, from estimates (69) and (71), we have the desired estimate for $\mathbf{H}_k^{(n)}$.

Now, applying Theorem 4 to problem (62), we have the following estimate:

$$\begin{aligned} & |U^{(n+1)}|_{\Omega_{0T}}^{(2+\alpha, 1+(\alpha/2))} + \|Q^{(n+1)}\|_T + |R^{(n+1)}|_{\Gamma_{0T}}^{(2+\alpha, 1+(\alpha/2))} \\ & \leq C_6 \left\{ \epsilon \left(|U^{(n)}|_{\Omega_{0T}}^{(2+\alpha, 1+(\alpha/2))} + |R^{(n)}|_{\Gamma_{0T}}^{(2+\alpha, 1+(\alpha/2))} \right) \right. \\ & \quad \left. + C(\epsilon) \int_0^T \left(|U^{(n)}|_{\Omega_{0\tau}}^{(2+\alpha, 1+(\alpha/2))} + |R^{(n)}|_{\Gamma_{0\tau}}^{(2+\alpha, 1+(\alpha/2))} \right) d\tau \right\}, \end{aligned} \quad (72)$$

where the norm $\|f\|_T$ is defined as $\|f\|_T \equiv |f|_{\Omega_{0T}}^{(1+\alpha, \gamma)} + |\nabla f|_{\Omega_{0T}}^{(\alpha, (\alpha/2))} + |f|_{\Gamma_{0T}}^{(1+\alpha, ((1+\alpha)/2))}$. Fixing ϵ so that $C_6\epsilon \leq 1/2$ and summing the above inequalities from $n = 1$ to $n = m$, we have

$$S_m(T) \leq C_7 \left(S_1(T) + \int_0^T S_m(\tau) d\tau \right), \quad (73)$$

where

$$S_m(T) \equiv \sum_{n=1}^m \left(|U^{(n)}|_{\Omega_{0T}}^{(2+\alpha, 1+(\alpha/2))} + \|Q^{(n)}\|_T + |R^{(n)}|_{\Gamma_{0T}}^{(\alpha, (\alpha/2))} \right). \quad (74)$$

Then, using Gronwall's inequality, from the above inequality, we have

$$S_m(T) \leq C_8 \left(1 + T e^{C_9 T} \right). \quad (75)$$

Noting that the right-hand side in (75) is independent of m , we can conclude that the sequence $\{(\mathbf{u}_m, q_m, r_m^s)\}$ is convergent in $C^{2+\alpha, 1+(\alpha/2)}(\Omega_{0T}) \times (C^{1+\alpha, \gamma}(\Omega_{0T}) \cap C^{1+\alpha, ((1+\alpha)/2)}(\Gamma_{0T})) \times C^{2+\alpha, 1+(\alpha/2)}(\Gamma_{0T})$.

Now, let us prove Theorem 1. Taking the limit as n tends to infinity in problem (3), we can easily see that the limit of the sequence $\{(\mathbf{u}_m, q_m, r_m^s)\}$ is a solution of problem (11)–(13). The uniqueness can be proved as follows. Let $(\mathbf{u}, q, r^s)$ and $(\tilde{\mathbf{u}}, \tilde{q}, \tilde{r}^s)$ be two solutions of problem (11)–(13). By subtracting one equation from the other, we obtain the equations for the differences $V \equiv \mathbf{u} - \tilde{\mathbf{u}}$, $P \equiv q - \tilde{q}$, and $R \equiv r^s - \tilde{r}^s$, the form of which is similar to (62). Then, in a similar manner to obtain (72), we can obtain the following estimate:

$$\begin{aligned} & |V|_{\Omega_{0T}}^{(2+\alpha, 1+(\alpha/2))} + |R|_{\Gamma_{0T}}^{(2+\alpha, 1+(\alpha/2))} \\ & \leq C_{10} \left\{ \epsilon \left(|V|_{\Omega_{0T}}^{(2+\alpha, 1+(\alpha/2))} + |R|_{\Gamma_{0T}}^{(2+\alpha, 1+(\alpha/2))} \right) \right. \\ & \quad \left. + C(\epsilon) \int_0^T \left(|V|_{\Omega_{0\tau}}^{(2+\alpha, 1+(\alpha/2))} + |R|_{\Gamma_{0\tau}}^{(2+\alpha, 1+(\alpha/2))} \right) d\tau \right\}. \end{aligned} \quad (76)$$

This inequality implies that $V = \mathbf{0}$ and $R = 0$, and as a consequence, $P = 0$ follows. Thus, the proof of Theorem 1 is completed.
