For a mixed stochastic Volterra equation driven by Wiener process and fractional Brownian motion with Hurst parameter $H > 1/2$, we prove an existence and uniqueness result for this equation under suitable assumptions.

1. Introduction

In recent years, there has been considerable interest in studying fractional Brownian motion (fBm) due to some of its compact properties such as self-similarity, stationary increments, Hölder's continuity, and long-range dependence (when $H > 1/2$), and also due to its applications in various scientific areas including telecommunications, turbulence, image processing, finance, and other fields. It is a suitable generalization of standard Wiener process. Some surveys and complete literatures could be found in Biagini et al. [1], Hu [2], Mishura [3], Nualart [4], and Zähle [5]. The so-called fBm with index $H \in (0, 1)$ is a zero mean Gaussian process $B^H = \{B_t^H, t \geq 0\}$ with the covariance:

$$E[B_t^H B_s^H] = \frac{1}{2} [s^{2H} + t^{2H} - |t - s|^{2H}]. \quad (1)$$

Since B^H is neither a semimartingale nor a Markov process unless $H = 1/2$, the classical Itô theory is not available when dealing with it. There are several approaches to define an integral with respect to fBm. One possibility is Skorokhod or divergence integral introduced in the fractional Brownian setting in Decreusefond and Üstünel [6]. We will use a pathwise integral, defined first in Zähle [5], for fBm with

$H > 1/2$ as a Young integral. The aim of this paper is to study the following mixed stochastic Volterra equation on $\mathbb{R}^d$:

$$X_t = X_0 + \int_0^t a(t, s, X_s) ds + \int_0^t b(t, s, X_s) dW_s + \int_0^t c(t, s, X_s) dB_s^H, \quad t \in [0, T], \quad (2)$$

where $a = (a^i)_{d \times 1} : [0, T]^2 \times \mathbb{R}^d \rightarrow \mathbb{R}^d$, $b = (b^{i,j})_{d \times r} : [0, T]^2 \times \mathbb{R}^d \rightarrow \mathbb{R}^d \times \mathbb{R}^r$, $c = (c^{i,j})_{d \times m} : [0, T]^2 \times \mathbb{R}^d \rightarrow \mathbb{R}^d \times \mathbb{R}^m$, W is an r -dimensional standard Wiener process, and B^H is an m -dimensional fBm with $H > 1/2$. We assume that the processes W and B^H are independent, the integral with respect to W is Itô type, and the integral with respect to B^H is a pathwise Riemann-Stieltjes integral in the sense of Zähle [5].

The mixed stochastic differential equation:

$$X_t = X_0 + \int_0^t a(s, X_s) ds + \int_0^t b(s, X_s) dW_s + \int_0^t c(s, X_s) dB_s^H, \quad t \in [0, T] \quad (3)$$

was first considered in Kubilius [7], where unique solvability was proved in one-dimensional case for time-independent coefficients and zero drift; that is, $a = 0$. Later, in Zähle [8], existence of a solution to (3) was proved under less

restrictive assumptions, but only locally, that is, up to a random time. In Guerra and Nualart [9], global existence and uniqueness of solution to (3) was established under the assumption that W and B^H are independent. The latter result was obtained in Mishura and Shevchenko [10, 11] without the independence assumptions, and it was also shown in Mishura and Shevchenko [11] that all moments of the solution are finite for $H > 3/4$. The motivation to consider such equations comes from some financial applications, where Wiener process as a model is inappropriate because of the lack of memory, and fBm with $H > 1/2$ is too smooth. A model driven by both processes is free of such drawbacks. Stochastic Volterra equations are also studied by many authors (see, e.g., [12–16]). In this paper, we consider the mixed stochastic Volterra equations driven by both Wiener process and fBm, and also give an existence and uniqueness result for this equation under suitable assumptions.

This paper is organized as follows. Section 2 contains some preliminaries on function spaces and lists our assumptions on the coefficients of (2). It also states the main results in this section. In Section 3, we will give some estimates of fractional and Itô integrals, based on the fractional calculus. Finally, in Section 4, we will prove Theorem 1 using the classical Yamada and Watanabe theorem [17, 18] to check the pathwise uniqueness property and the existence of weak solutions of (2).

2. Preliminaries and Main Results

Let $(\Omega, \mathcal{F}, P)$ be a complete probability space equipped with a filtration satisfying standard assumptions. Denote $B^H = \{B_t^H, t \in [0, T]\}$ an m -dimensional fBm with $H > 1/2$ and $W = \{W_t, t \in [0, T]\}$ an r -dimensional standard Wiener process, independent of B^H . X_0 is a d -dimensional random variable independent of (B^H, W) . For each $t \in [0, T]$, we denote by $\mathcal{F}_t$ the σ -field generated by the random variables $\{X_0, B_s^H, W_s, s \in [0, t]\}$ and the P -null sets. $\{\mathcal{G}_t, t \in [0, T]\}$ denotes the bigger filtrations such that $\{\mathcal{G}_t\}$ is right-continuous and $\mathcal{G}_0$ contains the P -null sets, X_0, B^H are $\mathcal{G}_0$ -measurable, and W is a $\mathcal{G}_t$ -Wiener process.

Let us now introduce some function spaces for later use. Letting $1/2 < H < 1$ and $\alpha \in (1 - H, 1/2)$, for any measurable function $f : [0, T] \rightarrow \mathbb{R}^d$, we introduce the following notation:

$$\|f(t)\|_\alpha := |f(t)| + \int_0^t \frac{|f(t) - f(s)|}{(t-s)^{\alpha+1}} ds. \quad (4)$$

Denote by $W_0^{\alpha, \infty}$ the space of measurable function $f : [0, T] \rightarrow \mathbb{R}^d$ such that

$$\|f\|_{\alpha, \infty} := \sup_{t \in [0, T]} \|f(t)\|_\alpha < \infty. \quad (5)$$

For any $0 < \lambda \leq 1$, let C^λ be space of λ -Hölder continuous functions $f : [0, T] \rightarrow \mathbb{R}^d$ such that

$$\|f\|_\lambda := \|f\|_\infty + \sup_{0 \leq s < t \leq T} \frac{|f(t) - f(s)|}{(t-s)^\lambda} < \infty, \quad (6)$$

where $\|f\|_\infty := \sup_{t \in [0, T]} |f(t)|$. Given any $0 < \varepsilon < \alpha$, we have the following inclusions:

$$C^{\alpha+\varepsilon} \subset W_0^{\alpha, \infty} \subset C^{\alpha-\varepsilon}. \quad (7)$$

Notice that both the fBm B^H with $H > 1/2$ and the standard Wiener process W have their trajectories in $W_0^{\alpha, \infty}$.

In what follows, we will assume the following standard hypotheses. Throughout the paper, the symbol C will denote a generic constant, whose value is not significant and can change from one line to another. To emphasize its dependence on some parameters, we will put them into subscripts consider the following.

(H₁) $a : [0, T]^2 \times \mathbb{R}^d \rightarrow \mathbb{R}^d$ is a measurable function such that there exists $a_0 \in L^p([0, T]^2; \mathbb{R}^d)$ with $\rho \geq 2$, $0 < \mu \leq 1$ and for all $N \geq 0$ there exists $C > 0$ such that

$$\begin{aligned} |a(t, s, x) - a(t, s, y)| &\leq C|x - y|, \\ |a(t_1, s, x) - a(t_2, s, x)| &\leq C|t_1 - t_2|^\mu, \\ |a(t, s, x)| &\leq C(1 + |x|), \end{aligned} \quad (8)$$

$$\begin{aligned} |a(t_1, s, x_1) - a(t_1, s, x_2) - a(t_2, s, x_1) + a(t_2, s, x_2)| \\ \leq C|t_1 - t_2||x_1 - x_2|, \end{aligned}$$

for all $x, y, x_1, x_2 \in \mathbb{R}^d$ and $s, t, t_1, t_2 \in [0, T]$.

(H₂) $b : [0, T]^2 \times \mathbb{R}^d \rightarrow \mathbb{R}^d \times \mathbb{R}^m$ is a measurable function and there exists a constant $C > 0$ such that

$$\begin{aligned} |b(t, s, x) - b(t, s, y)| &\leq C|x - y|, \\ |b(t, s, x)| &\leq C(1 + |x|), \end{aligned} \quad (9)$$

for all $x, y \in \mathbb{R}^d$ and $s, t \in [0, T]$.

(H₃) $c : [0, T]^2 \times \mathbb{R}^d \rightarrow \mathbb{R}^d \times \mathbb{R}^m$ is a measurable function. Moreover, there exist the derivatives $\partial_x c(t, s, x)$, $\partial_t c(t, s, x)$, $\partial_{x,t}^2 c(t, s, x)$ and constants $0 < \beta, \mu, \delta \leq 1$ and $C > 0$ such that the following properties hold:

$$\begin{aligned} |c(t, s, x) - c(t, s, y)| \\ + |\partial_t c(t, s, x) - \partial_t c(t, s, y)| &\leq C|x - y|, \\ |\partial_{x_i} c(t, s, x) - \partial_{x_i} c(t, s, y)| \\ + |\partial_{x_i,t}^2 c(t, s, x) - \partial_{x_i,t}^2 c(t, s, y)| &\leq C|x - y|^\delta, \\ |c(t_1, s, x) - c(t_2, s, x)| \\ + |\partial_{x_i} c(t_1, s, x) - \partial_{x_i} c(t_2, s, x)| &\leq C|t_1 - t_2|^\mu, \\ |c(t, s_1, x) - c(t, s_2, x)| \\ + |\partial_t c(t, s_1, x) - \partial_t c(t, s_2, x)| &\leq C|s_1 - s_2|^\beta, \\ |\partial_{x_i,t}^2 c(t, s_1, x) - \partial_{x_i,t}^2 c(t, s_2, x)| \\ + |\partial_{x_i} c(t, s_1, x) - \partial_{x_i} c(t, s_2, x)| &\leq C|s_1 - s_2|^\beta, \end{aligned} \quad (10)$$

for all $x, y \in \mathbb{R}^d$, $s, t, t_1, t_2, s_1, s_2 \in [0, T]$, $i = 1, 2, \dots, d$.

Denote by E^W the conditional expectation given $\mathcal{F}_0$, that is, given X_0 and B^H . A strong solution of (2) is a d -dimensional $\mathcal{F}_t$ -adapted stochastic process $\{X_t, t \in [0, T]\}$ such that a.s. the trajectories of X belong to $W_0^{\alpha, \infty}$ and $\int_0^T E^W \|X_s\|_\alpha^2 ds < \infty$, which satisfies (2) a.s. The main result of our paper is the following theorem on the existence and uniqueness of a solution for (2).

Theorem 1. Suppose that the coefficients a, b , and c satisfy the assumptions (H_1) , (H_2) , and (H_3) with $\beta > 1 - H$, $\delta > 1/H - 1$, $\min\{\beta, \delta/(\delta + 1)\} > 1 - \mu$, respectively. If $\max\{1 - H, 1 - \mu\} < \alpha < \min\{1/2, \beta, \delta/(\delta + 1)\}$ and $\rho \leq 1/\alpha$, then (2) has a unique strong solution X .

Notice that in all our results we can replace the fBm B^H with an arbitrary stochastic process with Hölder continuous trajectories of order $\lambda > 1/2$.

3. Integral Estimates

In this section, we will first briefly recall some basic definitions of fractional integrals and derivatives and define the integral with respect to fBm as a generalized Stieltjes integral (see, e.g., Nualart and Răşcanu [19] and Zähle [5]). We will also give some estimates of this integral.

Let $f \in L^1(a, b)$ and let $0 < \alpha < 1$. Consider the left-sided and right-sided fractional Riemann-Liouville integrals of f of order α :

$$\begin{aligned} I_{a^+}^\alpha f(x) &:= \frac{1}{\Gamma(\alpha)} \int_a^x f(t) (x-t)^{\alpha-1} dt, \\ I_{b^-}^\alpha f(x) &:= \frac{1}{\Gamma(\alpha)} \int_x^b f(t) (t-x)^{\alpha-1} dt, \end{aligned} \quad (11)$$

if the integrals exist for almost all $x \in (a, b)$ respectively, where $\Gamma(\cdot)$ denotes the gamma function defined by

$$\Gamma(z) = \int_0^\infty t^{z-1} e^{-t} dt, \quad z > 0. \quad (12)$$

Let $I_{a^+}^\alpha(L^p)$ (resp., $I_{b^-}^\alpha(L^p)$) be the image of $L^p(a, b)$, by the operator $I_{a^+}^\alpha$ (resp., $I_{b^-}^\alpha$). If $f \in I_{a^+}^\alpha(L^p)$ (resp., $I_{b^-}^\alpha(L^p)$) then the Weyl derivatives of f :

$$\begin{aligned} D_{a^+}^\alpha f(x) &:= \frac{1}{\Gamma(1-\alpha)} \left(\frac{f(x)}{(x-a)^\alpha} \right. \\ &\quad \left. + \alpha \int_a^x \frac{f(x) - f(t)}{(x-t)^{\alpha+1}} dt \right) 1_{(a,b)}(x), \end{aligned}$$

$$\begin{aligned} D_{b^-}^\alpha f(x) &:= \frac{1}{\Gamma(1-\alpha)} \left(\frac{f(x)}{(b-x)^\alpha} \right. \\ &\quad \left. + \alpha \int_x^b \frac{f(x) - f(t)}{(t-x)^{\alpha+1}} dt \right) 1_{(a,b)}(x) \end{aligned} \quad (13)$$

are defined for almost all $x \in (a, b)$ (the convergence of the integrals at the singularity $t = x$ holds pointwise for almost all $x \in (a, b)$ if $p = 1$ and moreover in L^p -sense if $1 < p < \infty$), respectively.

Let $f(a+) := \lim_{\varepsilon \searrow 0} f(a+\varepsilon)$ and let $g(b-) := \lim_{\varepsilon \searrow 0} g(b-\varepsilon)$ (supposing that the limits exist and are finite) and define

$$\begin{aligned} f_{a^+}(x) &:= (f(x) - f(a+)) 1_{(a,b)}(x), \\ g_{b^-}(x) &:= (g(x) - g(b-)) 1_{(a,b)}(x). \end{aligned} \quad (14)$$

Assuming that $f(a+)$, $g(a+)$, $g(b-)$ exists, $f_{a^+} \in I_{a^+}^\alpha(L^p)$ and $g_{b^-} \in I_{b^-}^{1-\alpha}(L^p)$ for some $p, q \geq 1$, $(1/p) + (1/q) \leq 1$, $0 < \alpha < 1$, the generalized Stieltjes Integral is defined as

$$\begin{aligned} \int_a^b f dg &:= (-1)^\alpha \int_a^b D_{a^+}^\alpha f_{a^+}(x) D_{b^-}^{1-\alpha} g_{b^-}(x) dx \\ &\quad + f(a+)(g(b-) - g(a+)). \end{aligned} \quad (15)$$

The following properties hold.

(i) If $\alpha p < 1$, under the preceding assumptions we have $f \in I_{a^+}^\alpha(L^p)$ and we can write

$$\int_a^b f dg := (-1)^\alpha \int_a^b D_{a^+}^\alpha f_{a^+}(x) D_{b^-}^{1-\alpha} g_{b^-}(x) dx. \quad (16)$$

(ii) If $f \in C^\lambda(a, b)$ and $g \in C^\mu(a, b)$ with $\lambda + \mu > 1$, then the generalized Stieltjes integral exists; it is given by (16) and coincides with the Riemann-Stieltjes integral.

The linear spaces $I_{a^+}^\alpha(L^p)$ are Banach spaces with respect to the norms:

$$\|f\|_{I_{a^+}^\alpha(L^p)} = \|f\|_{L^p} + \|D_{a^+}^\alpha f\|_{L^p} \sim \|D_{a^+}^\alpha f\|_{L^p}, \quad (17)$$

and the same is true for $I_{b^-}^\alpha(L^p)$. If $\alpha p < 1$ then the norms on $I_{a^+}^\alpha(L^p)$ and $I_{b^-}^\alpha(L^p)$ are equivalent and if $a \leq c < d \leq b$, then

$$\int_c^d f dg = \int_a^b 1_{(c,d)} f dg. \quad (18)$$

Fix a parameter $0 < \alpha < 1/2$; denote by $W_T^{1-\alpha, \infty}$ the space of measurable functions $g : [0, T] \rightarrow \mathbb{R}$ such that

$$\begin{aligned} \|g\|_{1-\alpha, \infty, T} &:= \sup_{0 < s < t < T} \left(\frac{|g(t) - g(s)|}{(t-s)^{1-\alpha}} \right. \\ &\quad \left. + \int_s^t \frac{|g(y) - g(s)|}{(y-s)^{2-\alpha}} dy \right) < \infty. \end{aligned} \quad (19)$$

Clearly,

$$C^{1-\alpha+\varepsilon} \subset W_T^{1-\alpha,\infty} \subset C^{1-\alpha}, \quad (20)$$

for all $\varepsilon > 0$. Moreover, if g belongs to $W_T^{1-\alpha,\infty}$, we define

$$\begin{aligned} \Lambda_\alpha(g) &:= \frac{1}{\Gamma(1-\alpha)} \sup_{0 < s < t < T} |(D_{t-}^{1-\alpha} g_{t-})(s)| \\ &\leq \frac{1}{\Gamma(1-\alpha)\Gamma(\alpha)} \|g\|_{1-\alpha,\infty,T} < \infty. \end{aligned} \quad (21)$$

We also denote by $W_0^{\alpha,1}$ the space of measurable functions $f : [0, T] \rightarrow \mathbb{R}$ such that

$$\begin{aligned} \|f\|_{\alpha,1} &:= \int_0^T \frac{|f(s)|}{s^\alpha} ds \\ &+ \int_0^T \int_0^s \frac{|f(s) - f(y)|}{(s-y)^{1+\alpha}} dy ds < \infty. \end{aligned} \quad (22)$$

Then, if $f \in W_0^{\alpha,1}$ and $g \in W_T^{1-\alpha,\infty}$, the integral $\int_0^t f(s) dg_s$ exists for all $t \in [0, T]$ and we have

$$\int_0^t f(s) dg_s = \int_0^T f(s) 1_{(0,t)}(s) dg_s. \quad (23)$$

Furthermore, the following estimate holds:

$$\left| \int_0^t f(s) dg_s \right| \leq \Lambda_\alpha(g) \|f\|_{\alpha,1}. \quad (24)$$

Given $f : [0, T]^2 \rightarrow \mathbb{R}$ such that for any $t \in [0, T]$, $f(t, \cdot) \in W_0^{\alpha,1}$, we can also consider the integral:

$$G_t(f) = \int_0^t f(t, s) dg_s = \int_0^T f(t, s) 1_{(0,t)}(s) dg_s \quad (25)$$

and the estimate:

$$\left| \int_0^t f(t, s) dg_s \right| \leq \Lambda_\alpha(g) \|f(t, \cdot)\|_{\alpha,1}. \quad (26)$$

Now we will derive some useful estimates for the integrals involved in (2). Fix a parameter $\alpha \in (0, 1/2)$. Consider first the ordinary Lebesgue integral. Given $f : [0, T] \rightarrow \mathbb{R}^d$ a measurable function we define

$$F_t^a(f) = \int_0^t a(t, s, f(s)) ds. \quad (27)$$

Proposition 2. Assume that a satisfies (H_1) with $\rho = 1/\alpha$ and $\mu > \alpha$. Let $f : [0, T] \rightarrow \mathbb{R}^d$ be a measurable function. If $f \in W_0^{\alpha,\infty}$, then $F_t^a(f) \in W_0^{\alpha,\infty}$, for all $t \in [0, T]$, one has

$$\|F_t^a(f)\|_\alpha \leq C \left(\int_0^t \frac{|f(s)|}{(t-s)^\alpha} ds + 1 \right). \quad (28)$$

Proof. It follows from Proposition 2.1 in Besalú and Rovira [15] and the growth assumption in (H_1) that

$$\begin{aligned} |F_t^a(f)| &+ \int_0^t \frac{|F_t^a(f) - F_s^a(f)|}{(t-s)^{\alpha+1}} ds \\ &\leq C \left(\int_0^t \frac{|a(t, s, f(s))|}{(t-s)^\alpha} ds + 1 \right) \\ &\leq C \left(\int_0^t \frac{1 + |f(s)|}{(t-s)^\alpha} ds + 1 \right) \\ &\leq C \left(\int_0^t \frac{|f(s)|}{(t-s)^\alpha} ds + 1 \right), \end{aligned} \quad (29)$$

as required. $\square$

Proposition 3. Assume that a satisfies (H_1) with $P = 1/\alpha$ and $\mu > \alpha$. Let $f, h : [0, T] \rightarrow \mathbb{R}^d$ be measurable functions. If $f, h \in W_0^{\alpha,\infty}$, then for all $t \in [0, T]$, one has

$$\|F_t^a(f) - F_t^a(h)\|_\alpha \leq C \left(\int_0^t \frac{\|f(s) - h(s)\|_\alpha}{(t-s)^\alpha} ds + 1 \right). \quad (30)$$

Proof. By Proposition 2.1 in Besalú and Rovira [15] and the growth assumption in (H_1) , one obtains

$$\begin{aligned} \|F_t^a(f) - F_t^a(h)\|_\alpha &\leq C \left(\int_0^t \frac{|a(t, s, f(s)) - a(t, s, h(s))|}{(t-s)^\alpha} ds + 1 \right) \\ &\leq C \left(\int_0^t \frac{|f(s) - h(s)|}{(t-s)^\alpha} ds + 1 \right) \\ &\leq C \left(\int_0^t \frac{\|f(s) - h(s)\|_\alpha}{(t-s)^\alpha} ds + 1 \right). \end{aligned} \quad (31)$$

$\square$

Given a measurable function $f : [0, T] \rightarrow \mathbb{R}^d$, let us define

$$G_t^c(f) = \int_0^t c(t, s, f(s)) dB_s^H. \quad (32)$$

Notice that if $f \in W_0^{\alpha,\infty}$, one has $c(t, \cdot, f(\cdot)) \in W_0^{\alpha,\infty}$.

Proposition 4. Assume that c satisfies (H_3) with $1 - \mu < \alpha < \beta$, $f \in W_0^{\alpha,\infty}$, then $G_t^c(f) \in W_0^{\alpha,\infty}$ for all $t \in [0, T]$ and we have

$$\begin{aligned} \|G_t^c(f)\|_\alpha &\leq C \Lambda_\alpha(B^H) \\ &\times \int_0^t ((t-s)^{-2\alpha} + s^{-\alpha}) \\ &\times (1 + \|f(s)\|_\alpha) ds. \end{aligned} \quad (33)$$

Proof. It follows from Proposition 3.1 in Besalú and Rovira [15] and the growth assumption in (H_3) that

$$\begin{aligned} \|G_t^c(f)\|_\alpha &\leq C\Lambda_\alpha(B^H) \\ &\times \left(\int_0^t ((t-s)^{-2\alpha} + s^{-\alpha}) \right. \\ &\quad \left. \times \|c(t, \cdot, f(\cdot))\|_\alpha ds + 1 \right) \\ &\leq C\Lambda_\alpha(B^H) \int_0^t ((t-s)^{-2\alpha} + s^{-\alpha}) \\ &\quad \times (1 + \|f(s)\|_\alpha) ds. \end{aligned} \quad (34)$$

□

Proposition 5. Assume that c satisfies (H_3) with $1-\mu < \alpha < \beta$, $f, h \in W_0^{\alpha, \infty}$, then for all $t \in [0, T]$ one has

$$\begin{aligned} \|G_t^c(f) - G_t^c(h)\|_\alpha &\leq C\Lambda_\alpha(B^H) \int_0^t ((t-s)^{-2\alpha} + s^{-\alpha}) \\ &\quad \times (1 + \Delta f(s) + \Delta h(s)) \\ &\quad \times \|f(s) - h(s)\|_\alpha ds, \end{aligned} \quad (35)$$

where

$$\Delta f = \sup_{s \in [0, T]} \int_0^s \frac{|f(s) - f(u)|^\delta}{(s-u)^{\alpha+1}} du. \quad (36)$$

Proof. Following Proposition 3.1 in Besalú and Rovira [15] and the assumptions in (H_3) , we get that

$$\begin{aligned} \|G_t^c(f) - G_t^c(h)\|_\alpha &\leq C\Lambda_\alpha(B^H) \left[\int_0^t ((t-s)^{-2\alpha} + s^{-\alpha}) \right. \\ &\quad \left. \times \|c(t, \cdot, f(\cdot)) - c(t, \cdot, h(\cdot))\|_\alpha ds + 1 \right] \\ &\leq C\Lambda_\alpha(B^H) \left[\int_0^t ((t-s)^{-2\alpha} + s^{-\alpha}) \right. \\ &\quad \times \left(|c(t, s, f(s)) - c(t, s, h(s))| \right. \\ &\quad \left. + \int_0^s \left(|c(t, s, f(s)) - c(t, s, h(s)) \right. \right. \\ &\quad \left. \left. - c(t, u, f(u)) + c(t, u, h(u)) \right| \right. \\ &\quad \left. \times ((s-u)^{\alpha+1})^{-1} du \right) ds + 1 \Big]. \end{aligned} \quad (37)$$

By Lemma A.1 of Besalú and Rovira [15], the hypothesis (H_3) imply that for all $x_i, \in \mathbb{R}, i = 1, \dots, 4, t, s_1, s_2 \in [0, T]$, one has

$$\begin{aligned} &|c(t, s_1, x_1) - c(t, s_2, x_2) - c(t, s_1, x_3) + c(t, s_2, x_4)| \\ &\leq C \left(|x_1 - x_2 - x_3 + x_4| + |x_1 - x_3| |s_2 - s_1|^\beta \right. \\ &\quad \left. + |x_1 - x_3| \left(|x_1 - x_2|^\delta + |x_3 - x_4|^\delta \right) \right). \end{aligned} \quad (38)$$

Thus, we obtain that

$$\begin{aligned} \|G_t^c(f) - G_t^c(h)\|_\alpha &\leq C\Lambda_\alpha(B^H) \left[\int_0^t ((t-s)^{-2\alpha} + s^{-\alpha}) (1 + \Delta f(s) + \Delta h(s)) \right. \\ &\quad \times \left(|f(s) - h(s)| \right. \\ &\quad \left. + \int_0^s \left(|f(s) - h(s) - f(u) + h(u)| \right. \right. \\ &\quad \left. \left. \times ((s-u)^{\alpha+1})^{-1} du \right) ds + 1 \right] \\ &\leq C\Lambda_\alpha(B^H) \int_0^t ((t-s)^{-2\alpha} + s^{-\alpha}) (1 + \Delta f(s) + \Delta h(s)) \\ &\quad \times \|f(s) - h(s)\|_\alpha ds. \end{aligned} \quad (39)$$

This completes the proof. □

Finally, we will consider the estimate of Itô integral based on the Itô calculus. Let $f : [0, T] \rightarrow \mathbb{R}^d$ be a measurable function and define

$$G_t^b(f) = \int_0^t b(t, s, f(s)) dW_s. \quad (40)$$

Proposition 6. Let $f : [0, T] \rightarrow \mathbb{R}^d$ be a $\mathcal{G}_t$ -adapted stochastic process. If $f \in W_0^{\alpha, \infty}$ and $\int_0^T E^W \|f(s)\|_\alpha^2 ds < \infty$ a.s., then for all $t \in [0, T]$ a.e., one has

$$E^W \|G_t^b(f)\|_\alpha^2 \leq C \int_0^t (t-s)^{-(1/2)-\alpha} [1 + E^W \|f(s)\|_\alpha^2] ds. \quad (41)$$

Proof. It follows from Lemma 3.7 in Guerra and Nualart [9] and the growth assumption in (H_2) . □

Proposition 7. Let $f, h : [0, T] \rightarrow \mathbb{R}^d$ be $\mathcal{G}_t$ -adapted stochastic processes. If $f, h \in W_0^{\alpha, \infty}$ and $\int_0^T E^W \|\phi(s)\|_\alpha^2 ds < \infty$, $\phi \in \{f, h\}$ a.s., then for all $t \in [0, T]$ a.e., one has

$$\begin{aligned} E^W \|G_t^b(f) - G_t^b(h)\|_\alpha^2 &\leq C \int_0^t (t-s)^{-(1/2)-\alpha} E^W |f(s) - h(s)|^2 ds. \end{aligned} \quad (42)$$

Proof. By Lemma 3.7 in Guerra and Nualart [9] and the Lipschitz assumption in (H_2) , one has

$$\begin{aligned} E^W \|G_t^b(f) - G_t^b(h)\|_\alpha^2 &\leq C \int_0^t (t-s)^{-(1/2)-\alpha} E^W |b(t, s, f(s)) - b(t, s, h(s))|^2 ds \\ &\leq C \int_0^t (t-s)^{-(1/2)-\alpha} E^W |f(s) - h(s)|^2 ds, \end{aligned} \quad (43)$$

which completes the proof. $\square$

4. Proof of the Theorem 1

To prove Theorem 1, we will use the classical Yamada and Watanabe theorem [17, 18], which asserts that pathwise uniqueness and existence of weak solutions imply the existence of a strong solution. A weak solution of (2) in this paper is a triple $(\Omega, \mathcal{F}, P)$, (X, B^H, W) , $\{\mathcal{G}_t, t \in [0, T]\}$ such that:

- (i) $(\Omega, \mathcal{F}, P)$ is a complete probability space, $\{\mathcal{G}_t\}$ is right-continuous, and $\mathcal{G}_0$ contains the P -null sets,
- (ii) B^H is a fBm which is $\mathcal{G}_0$ -measurable,
- (iii) W is a $\mathcal{G}_t$ - r -dimensional Wiener process,
- (iv) X is $\mathcal{G}_t$ -adapted and has the trajectories belong to $W_0^{\alpha, \infty}$ and $\int_0^T E^W \|X_s\|_\alpha^2 ds < \infty$ a.s.,
- (v) (X, B^H, W) satisfies (2) a.s.

The pathwise uniqueness property holds for (2) means that if (X, B^H, W) and (Y, B^H, W) are two weak solutions, defined on the same probability space $(\Omega, \mathcal{F}, P)$ with the same filtration $\{\mathcal{G}_t\}$ and $X_0 = Y_0$ a.s., then $X = Y$.

Let $f \in W_0^{\alpha, \infty}$. By Propositions 2.2 and 3.2 in Besalú and Rovira [15], the sample paths of the integral processes $G_t^a(f)$ and $G_t^c(f)$ are continuously differentiable and η -Hölder continuous of order $\eta < 1 - \alpha$, respectively. Therefore, if X is a weak solution of (2), then the trajectories of X are η -Hölder continuous for all $\eta < 1/2$. Consequently, the pathwise uniqueness property holds for (2). It is exactly the same result as that of Theorem 4.4 given in Guerra and Nualart [9]. So it remains to prove that the existence of weak solutions for (2).

Let us now introduce the Euler approximation for (2). Take a sequence of partitions

$$0 = t_0^n < t_1^n < \cdots < t_i^n < \cdots < t_n^n = T \quad (44)$$

of the interval $[0, T]$ such that

$$\sup_{0 \leq i \leq n-1} |t_{i+1}^n - t_i^n| \longrightarrow 0 \quad (45)$$

as $n \rightarrow \infty$. Defined as $X_t^0 = X_0$ and for all $n \geq 1$,

$$\begin{aligned} X_t^n &= X_0 + \int_0^t a(t, v_n(s), X_{v_n(s)}^n) ds \\ &\quad + \int_0^t b(t, v_n(s), X_{v_n(s)}^n) dW_s \\ &\quad + \int_0^t c(t, v_n(s), X_{v_n(s)}^n) dB_s^H, \end{aligned} \quad (46)$$

where $v_n(t) = \max\{t_i^n : t_i^n \leq t\}$. We first prove the tightness of the law of the sequence $\{X^n(t)\}$ in the space C_0^η of η -Hölder continuous functions, with $\eta < 1/2$, such that

$$\lim_{\varepsilon \rightarrow 0} \sup_{0 < |t-s| < \varepsilon} \frac{|f(t) - f(s)|}{(t-s)^\eta} = 0. \quad (47)$$

Using the criterion given by Hamadouche [20], is sufficient to prove the following lemma.

Lemma 8. For any $N \geq 1$, there exists a random variable $R_N > 0$, depending on X_0 and B^H , such that

$$E^W [|X_t^n - X_s^n|^{2N}] \leq R_N |t - s|^N \quad (48)$$

for all $s, t \in [0, T]$ and $n \in \mathbb{N}$.

Proof. Firstly, we will show that there exists a random variable $K_N > 0$ such that

$$E^W \|X_t^n\|_\alpha^{2N} \leq K_N \quad (49)$$

for all $t \in [0, T]$ and $n \in \mathbb{N}$. In fact, from (46), we have

$$\begin{aligned} E^W \|X_t^n\|_\alpha^{2N} &\leq C_N \left\{ |X_0|^{2N} + E^W \left\| \int_0^t a(t, v_n(s), X_{v_n(s)}^n) ds \right\|_\alpha^{2N} \right. \\ &\quad + E^W \left\| \int_0^t b(t, v_n(s), X_{v_n(s)}^n) dW_s \right\|_\alpha^{2N} \\ &\quad \left. + E^W \left\| \int_0^t c(t, v_n(s), X_{v_n(s)}^n) dB_s^H \right\|_\alpha^{2N} \right\} \\ &:= C_N (|X_0|^{2N} + A_1 + A_2 + A_3). \end{aligned} \quad (50)$$

Using the estimate (28) and Hölder inequality, we get that

$$\begin{aligned} A_1 &\leq C_N E^W \left(\int_0^t \frac{|X_{v_n(s)}^n|}{(t-s)^\alpha} ds + 1 \right)^{2N} \\ &\leq C_N E^W \left(\int_0^t |X_{v_n(s)}^n|^2 ds \right)^N + C_N \\ &\leq C_N E^W \left(\int_0^t |X_{v_n(s)}^n|^{2N} ds \right) + C_N. \end{aligned} \quad (51)$$

And also

$$\begin{aligned} A_2 &\leq C_N E^W \left| \int_0^t b(t, v_n(s), X_{v_n(s)}^n) dW_s \right|^{2N} \\ &\quad + C_N E^W \left(\int_0^t \frac{\left| \int_s^t b(t, v_n(u), X_{v_n(s)}^n) dW_u \right|}{(t-s)^{\alpha+1}} ds \right)^{2N} \\ &:= A_{21} + A_{22}. \end{aligned} \quad (52)$$

By Burkholder-Davis-Gundy and Hölder inequalities, we obtain

$$\begin{aligned} A_{21} &\leq C_N E^W \left[\int_0^t |b(t, v_n(s), X_{v_n(s)}^n)|^{2N} ds \right] \\ &\leq C_N \int_0^t [1 + E^W |X_{v_n(s)}^n|^{2N}] ds. \end{aligned} \quad (53)$$

Similarly, we get

$$\begin{aligned} A_{22} &\leq C_N \left(\int_0^t \frac{1}{(t-s)^{(2N/(2N-1))(\alpha+(1/2)-((1/2)+\alpha)/2N))} ds \right)^{2N-1} \\ &\quad \times E^W \left(\int_0^t \frac{\left| \int_s^t b(t, v_n(u), X_{v_n(s)}^n) dW_u \right|^{2N}}{(t-s)^{\alpha+N+(1/2)}} ds \right) \\ &\leq C_N \int_0^t (t-s)^{-(3/2)-\alpha} \\ &\quad \times E^W \left[\int_s^t |b(t, v_n(u), X_{v_n(s)}^n)|^{2N} du \right] ds. \end{aligned} \quad (54)$$

Now applying Fubini's theorem and using the growth assumption in (H_2) , we have

$$A_{22} \leq C_N \int_0^t (t-u)^{-(1/2)-\alpha} (1 + E^W |X_{v_n(s)}^n|^{2N}) du. \quad (55)$$

As a consequence,

$$A_2 \leq C_N \int_0^t (t-u)^{-(1/2)-\alpha} E^W |X_{v_n(s)}^n|^{2N} du + C_N. \quad (56)$$

Further, applying the estimate (33) and Hölder inequality, we get

$$\begin{aligned} A_3 &\leq C_N \Lambda_\alpha (B^H)^{2N} \\ &\quad \times E^W \left[\int_0^t ((t-s)^{-2\alpha} + s^{-\alpha}) \right. \\ &\quad \times \left. \left(\|c(t, v_n(s), X_{v_n(s)}^n)\|_\alpha \right) ds \right]^{2N} \\ &\leq C_N \Lambda_\alpha (B^H)^{2N} \int_0^t ((t-s)^{-2\alpha} + s^{-\alpha}) \\ &\quad \times [1 + E^W \|X_{v_n(s)}^n\|_\alpha^{2N}] ds. \end{aligned} \quad (57)$$

Combining these estimates, we have

$$\begin{aligned} E^W \|X_t^n\|_\alpha^{2N} &\leq C_N |X_0|^{2N} + C_N (\Lambda_\alpha (B^H)^{2N} + 1) \\ &\quad \times \int_0^t ((t-s)^{-(1/2)-\alpha} + s^{-\alpha}) \\ &\quad \times E^W \|X_{v_n(s)}^n\|_\alpha^{2N} ds. \end{aligned} \quad (58)$$

Hence,

$$\begin{aligned} \sup_{0 \leq s \leq t} E^W \|X_s^n\|_\alpha^{2N} &\leq C_N |X_0|^{2N} + C_N (\Lambda_\alpha (B^H)^{2N} + 1) \\ &\quad \times \int_0^t ((t-s)^{-(1/2)-\alpha} + s^{-\alpha}) \\ &\quad \times \left(\sup_{0 \leq u \leq s} E^W \|X_u^n\|_\alpha^{2N} \right) ds. \end{aligned} \quad (59)$$

Therefore, by the generalized Gronwall lemma (Lemma 7.6 in Nualart and Răşcanu [19]), the estimate (49) is satisfied.

So it remains to prove that the estimate (48) is satisfied. Indeed, from (46), we have

$$\begin{aligned} E^W |X_t^n - X_s^n|^{2N} &\leq C_N \left\{ E^W \left| \int_s^t a(t, v_n(u), X_{v_n(s)}^n) du \right|^{2N} \right. \\ &\quad + E^W \left| \int_s^t b(t, v_n(u), X_{v_n(s)}^n) dW_u \right|^{2N} \\ &\quad + E^W \left| \int_s^t c(t, v_n(u), X_{v_n(s)}^n) dB_u^H \right|^{2N} \Big\} \\ &:= B_1 + B_2 + B_3. \end{aligned} \quad (60)$$

It follows from the growth assumption in (H_1) , the estimate (49), and Hölder inequality that

$$\begin{aligned} B_1 &\leq C_N (t-s)^{2N-1} \\ &\quad \times \int_s^t E^W |a(t, v_n(u), X_{v_n(s)}^n)|^{2N} du \\ &\leq R_N (t-s)^{2N}. \end{aligned} \quad (61)$$

By Burkholder-Davis-Gundy and Hölder inequalities and using the estimate (49), we obtain

$$\begin{aligned} B_2 &\leq C_N (t-s)^{N-1} \\ &\quad \times E^W \left[\int_s^t |b(t, v_n(u), X_{v_n(s)}^n)|^{2N} du \right] \\ &\leq R_N (t-s)^N. \end{aligned} \quad (62)$$

Finally, using the estimates (24) and (49), we get

$$\begin{aligned}
 B_3 &\leq C_N E^W \Lambda_\alpha (B^H)^{2N} (t-s)^{2N(1-\alpha)+2\alpha-1} \\
 &\quad \times \int_s^t \frac{\|c(t, v_n(u), X_{v_n(s)}^n)\|_\alpha^{2N}}{(u-s)^{2\alpha}} du \\
 &\leq R_N (t-s)^{2N(1-\alpha)+2\alpha-1} \\
 &\quad \times E^W \int_s^t \frac{1 + \|X_{v_n(s)}^n\|_\alpha^{2N}}{(u-s)^{2\alpha}} du \\
 &\leq R_N (t-s)^N.
 \end{aligned} \tag{63}$$

Summing up, we deduce the desired result. $\square$

Let $P^n = P \circ X^n$, $n \geq 0$, be the sequence of probability measure induced by X^n on C_0^η , then the sequence is tight (a similar result to Proposition 5.2 in Guerra and Nualart [9]).

Now, we can state that there exists a weak solution for (2), which follows the same computations to those given in Theorem 5.3 of Guerra and Nualart [9].

Theorem 9 (existence of weak solution). *Suppose that the coefficients a , b , and c satisfy the assumptions (H_1) , (H_2) , and (H_3) with $\beta > 1 - H$, $\delta > (1/H) - 1$, $\min\{\beta, \delta/(\delta+1)\} > 1 - \mu$, respectively. If $\max\{1 - H, 1 - \mu\} < \alpha < \min\{1/2, \beta, \delta/(\delta+1)\}$ and $\rho \leq 1/\alpha$, then (2) has a unique weak solution.*

Therefore, by the classical Yamada and Watanabe theorem [17, 18], Theorem 1 will be an immediate consequence of the pathwise uniqueness property and the existence of weak solutions (Theorem 9).
