Abstract

We investigate the problem of coordinated formation control for multiple surface vessels in the presence of unknown external disturbances. In order to realize the leaderless coordinated formation and achieve the robustness against unknown external disturbances, a new robust coordinated formation control algorithm based on backstepping sliding mode control is proposed. The proposed coordinated control algorithm is achieved by defining a new switched function using the combination of position tracking error and cross-coupling error. Particularly, the cross-coupling error is defined using velocity tracking error and velocity synchronization error so as to be applicable for sliding mode controller design. Furthermore, the adaptive control law is proposed to estimate unknown disturbances for each vessel. The globally asymptotically stability is proved using the Lyapunov direct method. Finally, the effectiveness of the proposed coordinated formation control algorithm is demonstrated by corresponding simulations.

1. Introduction

Recently, coordination and consensus of multiagent systems have received much attention, and the network-induced constraints are discussed [1]. Many studies on coordination control issues have been widely reported in the existing literature due to the widespread applications, such as multiple mobile robots, spacecraft formation, networked sensors, vehicles coordination [2]. Particularly, the applications of formation control at sea are increasing, which can be found within both civil and military operations. For example, a group of surface vessels travel in formation structures to perform the seabed mapping operations, the collective range of sensor equipment can be maximized, ensuring that larger areas can be covered in shorter time compared with a single vessel. And another example is underway replenishment of vessels which is typically performed by one or more supply vessels lining up at the side of the receiving vessel, after which all vessels strive to maintain equal and constant forward speed and bearing while supplies are being transferred across messenger lines [3]. The complicated operations often cannot be carried out through only one vessel.

In a word, multiple vessels work together to improve performance and reduce fatigue and difficulty for the people involved. What is more, compared with a single vessel, multiple vessels perform the complicated tasks with less time and cost in practical maritime. So this paper will focus on the coordinated formation of multiple surface vessels; And the formation control in this paper aims at the surface vessels, then the robustness to environmental disturbances is highly important when considering the marine and offshore applications. So the study on the robust coordination control algorithm for multiple surface vessels is significative.

With respect to the coordination control issues of multiple surface vessels, abundant studies have been widely reported in the existing literature. There are several typical approaches used to design the coordination formation controller. For example, Lagrangian formation method [4], null-space-based behavioral control [5], nonlinear model predictive control [6], and graph theory [7]. Meanwhile the problem of coordinated path following for multiple vessels also has been discussed in the following references [8–10]. In recent years, the formation control of multiple vessels is researched using the passivity-based control method included in the
Abstract and Applied Analysis

2. Preliminaries

2.1. Notations. In this section, several basic concepts about the directed connected graph are given. A directed graph $G$ consists of the pair $(V, E)$, where $V$ is a set of vertices; $E \subseteq V^2$ is a set of edges. $(i, j) \in E$ if information flows from vertex $j$ to vertex $i$. If any two distinct vertices of a directed graph can be connected through a directed path, then the directed graph is called strongly connected. The adjacent matrix of the directed graph is denoted as $A \in \mathbb{R}^{n \times n}$, which is defined as diagonal entries 0 and off-diagonal entries $a_{ij} = 1$ if $(i, j) \in E$ and 0 otherwise. The degree matrix $D \in \mathbb{R}^{n \times n}$ is defined with off-diagonal entries 0 and diagonal entries $d_i = \sum_{j \neq i} a_{ij}$. Then the Laplacian matrix is obtained as $L = D - A \in \mathbb{R}^{n \times n}$. That is $L = [l_{ij}] \in \mathbb{R}^{n \times n}$, and $l_i = \sum_{j \neq i} l_{ij}, l_{ij} = -a_{ij}$.

In this paper, the communication topology between these vessels is described by a strongly connected graph. Each vertex in the graph represents a vessel in the group. The edges represent information exchange links by available communication.

Define the Kronecker product of two matrices $A \in \mathbb{R}^{m \times n}$ and $B \in \mathbb{R}^{p \times q}$ as

$$A \otimes B = \left[ \begin{array}{ccc} a_{11}B & \cdots & a_{1n}B \\ \vdots & \ddots & \vdots \\ a_{m1}B & \cdots & a_{mn}B \end{array} \right].$$

Theorem 1 (see [28]). Let $x = 0$ be an equilibrium point for $x = f(t, x)$, and let $D \subseteq \mathbb{R}^n$ be a domain containing $x = 0$. Let $V : [0, \infty) \times D \to \mathbb{R}$ be a continuously differentiable function such that

$$W_1(x) \leq V(t, x) \leq W_2(x),$$

$$\frac{\partial V}{\partial t} + \nabla V \cdot f(t, x) \leq W_5(x)$$

for all $t \geq 0$ and for all $x \in D$, where $W_1(x), W_2(x), W_5(x)$ are continuous positive definite functions on $D$. Then, $x = 0$ is uniformly asymptotically stable. If $D = \mathbb{R}^n$ and $W_5(x)$ is radially unbounded, then $x = 0$ is globally uniformly asymptotically stable.

Lemma 2 (Barbalat’s lemma [28]). Let $\phi : \mathbb{R} \to \mathbb{R}$ be a uniformly continuous function on $[0, \infty)$. Suppose that $\lim_{t \to \infty} \int_0^t \phi(r)dr$ exists and is finite. Then, $\phi(t) \to 0$ as $t \to \infty$.

2.2. Mathematical Vessel Model. The vessel model can be divided into two parts: the kinematics and nonlinear dynamics. Generally, only the motion in the horizontal plane is considered for the surface vessel. The elements corresponding to heave, roll, and pitch are neglected. The dynamic model for
the \( i \)th surface vessel can be represented by the following 3 degrees of freedom (DOF) [29]:

\[
\dot{\eta}_i = \mathbf{R}_i(\psi_i) \mathbf{v}_i,
\]

\[
\mathbf{M}_i \ddot{\eta}_i + \mathbf{C}_i(\eta_i, \dot{\eta}_i) \dot{\eta}_i + \mathbf{D}_i(\eta_i, \dot{\eta}_i) \dot{\eta}_i = \tau_i + \tau_{di},
\]

where \( \eta_i = [n_i, e_i, \psi_i]^T \) denotes the north position, east position, and orientation which are decomposed in the earth-fixed reference frame, and \( \mathbf{v}_i = [v_i, v_j, v_R]^T \) denotes the linear surge velocity, sway velocity and angular velocity, which are decomposed in the body-fixed reference frame. \( \mathbf{R}_i(\psi_i) \) is the transformations matrix from the body-fixed reference frame to the earth-fixed reference frame, the form of which is as follows:

\[
\mathbf{R}_i(\psi_i) = \begin{bmatrix}
\cos(\psi_i) & -\sin(\psi_i) & 0 \\
\sin(\psi_i) & \cos(\psi_i) & 0 \\
0 & 0 & 1
\end{bmatrix}.
\]

Then we can know that the transformations matrix satisfies the following properties as \( \mathbf{R}_i^{-1}(\psi_i) = \mathbf{R}_i^T(\psi_i) \), for all \( \psi_i \).

3. Coordinated Formation Controller Design

In this section, we will design the coordinated trajectory tracking controller for multiple surface vessels based on backstepping sliding mode control method. And we assume that all the vessels are disturbance-free. The detailed procedure of controller design is as follows.

3.1. Formation Setup. This paper considers a fleet of \( n \) vessels to perform the desired coordination formation task. And each vessel in the formation is identified by the index set \( I = \{1, 2, \ldots, n\} \). As in [12], the desired formation is established by defining the formation reference vector for each vessel, which is denotes as \( \mathbf{l}_i = [x_{i0}, y_{i0}, \psi_{i0}]^T \), where \( x_{i0}, y_{i0}, \psi_{i0} \) are constant, respectively, and \(-\pi \leq \psi_{i0} \leq \pi \). Then the formation reference point for each vessel is given by: \( \mathbf{x}_i = \eta_i + \mathbf{R}_i(\psi_i - \psi_{i0}) \mathbf{l}_i \). If we assume the desired trajectory of the formation point is denoted as \( \eta_d \), where \( \eta_d = [n_d(t), e_d(t), \psi_d(t)]^T \), \( n_d(t), e_d(t) \), \( \psi_d(t) \) are sufficiently smooth functions, and \( \psi_d(t) = \arctan(e_d(t)/n_d(t)) \). That means that the vessel direction is chosen as the tangential vector of the respective desired trajectory. We can know that the coordinated formation is achieved if all the formation reference points of the group of vessels are synchronized; that is \( \mathbf{x}_1 = \cdots = \mathbf{x}_n = \eta_d \).

3.2. Formation Controller Design. The proposed coordinated formation controller for multiple surface vessels is designed using the backstepping sliding mode control approach, and a new switched function is defined to accomplish the sliding mode controller.

Define the position tracking error of the formation reference point for each vessel as

\[
\mathbf{z}_{ii} = \mathbf{x}_i - \eta_{id} = \eta_i + \mathbf{R}_i(\psi_i - \psi_{i0}) \mathbf{l}_i - \eta_d.
\]

If we define the new variable \( \mathbf{f}_i \) as \( \mathbf{f}_i = \mathbf{R}_i(\psi_i - \psi_{i0}) \mathbf{l}_i \), take the derivative of \( \mathbf{z}_{ii} \), we can obtain that

\[
\dot{\mathbf{z}}_{ii} = \dot{\eta}_i + \dot{\mathbf{f}}_i - \dot{\eta}_d.
\]

Define the following stabilizing function for each vessel as

\[
\alpha_i = \lambda_i \mathbf{z}_{ii},
\]

where \( \lambda_i \in \mathbb{R}^{3 \times 3} \) is a diagonal positive definite matrix.

Define the velocity error as \( \mathbf{z}_{2i} \); the form of which is

\[
\mathbf{z}_{2i} = \mathbf{z}_{ii} + \alpha_i = \mathbf{z}_{ii} + \lambda_i \mathbf{z}_{ii}.
\]

Then we can obtain

\[
\dot{\mathbf{z}}_{2i} = \dot{\eta}_i + \dot{\mathbf{f}}_i - \dot{\eta}_d + \lambda_i \dot{\mathbf{z}}_{2i}.
\]

With the form of vessel model, then we have

\[
\mathbf{M}_n(\eta_i) \ddot{\mathbf{z}}_{2i} = \mathbf{M}_n(\eta_i) \left( \dot{\eta}_i + \dot{\mathbf{f}}_i - \dot{\eta}_d + \lambda_i \mathbf{z}_{ii} \right) \\
= \tau_i + \tau_{di} - \mathbf{C}_n(\eta_i, \dot{\eta}_i) \dot{\eta}_i - \mathbf{D}_n(\eta_i, \dot{\eta}_i) \dot{\eta}_i \\
+ \mathbf{M}_n(\eta_i) \ddot{\mathbf{f}}_i - \mathbf{M}_n(\eta_i) \ddot{\eta}_d + \mathbf{M}_n(\eta_i) \lambda_i \mathbf{z}_{2i}.
\]
In light of (16), we can obtain that
\[ \dot{\eta}_i = \dot{\eta}_d - f_i + z_2 - \lambda z_1. \] (18)

Then (17) can be calculated as follows
\[ M_{ni} (\eta_i) \dot{z}_{ni} = \tau_i + \tau_{di} - (C_n (\eta_i, \dot{\eta}_i) + D_n (\eta_i, \dot{\eta}_i)) (\dot{\eta}_d - \dot{f}_i) - (C_n (\eta_i, \dot{\eta}_i) + D_n (\eta_i, \dot{\eta}_i)) (z_2 - \lambda z_1). \]
\[ \tau_{di} = \lambda \text{diag}(\lambda_1, \lambda_2, \ldots, \lambda_n), \]
\[ M_n (\eta) = \text{diag}(M_{n1}(\eta_1), \ldots, M_{nn}(\eta_n)), \]
\[ C_n (\eta, \dot{\eta}) = \text{diag}(C_{n1}(\eta_1, \dot{\eta}_1), \ldots, C_{nn}(\eta_n, \dot{\eta}_n)), \]
\[ D_n (\eta, \dot{\eta}) = \text{diag}(D_{n1}(\eta_1, \dot{\eta}_1), \ldots, D_{nn}(\eta_n, \dot{\eta}_n)). \]

So the error dynamics of multiple surface vessels can be written in terms of matrix and vector:
\[ \dot{z}_i = z_2 - \lambda z_1, \]
\[ \dot{z}_2 = M_n^{-1} (\eta) \left[ \tau + \tau_{di} - M_n (\eta) (\dot{\eta}_d - \dot{f}_i) - (C_n (\eta, \dot{\eta}) + D_n (\eta, \dot{\eta})) (\dot{\eta}_d - \dot{f}_i) - (C_n (\eta, \dot{\eta}) + D_n (\eta, \dot{\eta})) (z_2 - \lambda z_1) + M_n (\eta) \lambda \dot{z}_1 \right]. \]

Define the synchronization velocity error vector for these vessels as
\[ e = (I \otimes I_3) z_2, \] (23)
where \( L \in \mathbb{R}^{3n \times 3n} \) is the Laplacian matrix of the communication topology graph for these vessels.

Define the cross-coupling error using the velocity error and the synchronization velocity error; the form of which is
\[ e = z_2 + y e = z_2 + y (L \otimes I_3) z_2 = (I_{3n} + y (L \otimes I_3)) z_2, \] (24)
where \( y \in \mathbb{R}^{3n \times 3} \) is a diagonal positive definite matrix.

The switched function is defined using the position tracking error and the cross-coupling error. The detailed form is as follows
\[ s = k z_1 + e \]
\[ = k z_1 + (I_{3n} + y (L \otimes I_3)) z_2, \] (25)
where \( k \in \mathbb{R}^{3n \times 3} \) is a diagonal positive definite matrix.

If we assume these vessels are disturbance-free; that is \( \tau_d = 0 \), then the control input can be chosen as follows
\[ \tau = \tau_{eq} + \tau_{sw}, \] (26)
where \( \tau_{eq} \) is the equivalent control input, and \( \tau_{sw} \) is the switch control part of the backstepping sliding mode control input. The detailed expressions are as follows:
\[ \tau_{eq} = M_n (\eta) \left( \dot{\eta}_d - \dot{f}_i \right) - M_n (\eta) \lambda z_1 + (C_n (\eta, \dot{\eta}) + D_n (\eta, \dot{\eta})) (\dot{\eta}_d - \dot{f}_i) + (C_n (\eta, \dot{\eta}) + D_n (\eta, \dot{\eta})) (z_2 - \lambda z_1) \]
\[ - M_n (\eta) \left( I_{3n} + y (L \otimes I_3) \right)^{-1} k (z_2 - \lambda z_1), \]
\[ \tau_{sw} = -M_n (I_{3n} + y (L \otimes I_3))^{-1} P (s + \beta \text{sign} (s)), \]
where \( P \in \mathbb{R}^{3n \times 3} \), \( \beta \in \mathbb{R}^{3n \times 3} \) are a diagonal positive definite matrix, respectively. And \( \text{sign} (\cdot) \) is sign function. And \( \text{sign} (s) = \text{sign} (s_1^T \cdot) \cdot \text{sign} (s_2^T \cdot) \cdot \text{sign} (s_3^T \cdot) \).

Remark 3. The control input vector for each vessel which is disturbance-free can be written as
\[ \tau_j = \tau_{eq} + \tau_{sw}. \] (28)

Define
\[ Y = (I_{3n} + y (L \otimes I_3))^{-1} \left\{ Y_{ij} \in \mathbb{R}^{3n \times 3} \right\} \in \mathbb{R}^{3n \times 3n}, \]
\[ y = \text{diag}(y_1, y_2, \ldots, y_n), \]
\[ k = \text{diag}(k_1, k_2, \ldots, k_n), \]
\[ P = \text{diag}(P_1, P_2, \ldots, P_n), \]
\[ \beta = \text{diag}(\beta_1, \beta_2, \ldots, \beta_n). \]

The detailed expressions of the control input for each vessel are as follows:
\[ \tau_{eq} = M_{ni} (\eta_i) \left( \dot{\eta}_d - \dot{f}_i \right) - M_{ni} (\eta_i) \lambda z_{si} + (C_{ni} (\eta_i, \dot{\eta}_i) + D_{ni} (\eta_i, \dot{\eta}_i)) (\dot{\eta}_d - \dot{f}_i) + (C_{ni} (\eta_i, \dot{\eta}_i) + D_{ni} (\eta_i, \dot{\eta}_i)) (z_{2i} - \lambda z_{si}) \]
\[ - M_{ni} (\eta_i) \sum_{j=1}^{n} Y_{ij} \left( k_j (z_{2j} - \lambda z_{sj}) \right) \]
\[ \tau_{sw} = -M_{ni} (\eta_i) \sum_{j=1}^{n} Y_{ij} P_j (s_j + \beta_j \text{sign} (s_j)), \]
where the switched function is defined as
\[ s_j = k_j z_{si} + z_{sj} + \gamma_j \sum_{i=1}^{n} a_{ji} (z_{2i} - z_{sj}), \] (31)
where \( A = [a_{ji}] \in \mathbb{R}^{n \times n} \) is the adjacency matrix for the communication topology graph. \( a_{ii} = 0 \) and \( a_{ji} = 1 \) if information flow from vessel \( i \) to vessel \( j \) and 0 otherwise, for all \( j \neq i \).
Theorem 4. Consider a group of \( n \) vessels to perform the coordination formation task; the vessel model is described as (3) and (4), and we assume that these vessels are disturbance-free. With the distributed coordinated formation control law (26) and (27), the following conditions are satisfied:

(i) all the matrices \( \lambda, \mathbf{P}, \) and \( \mathbf{k} \) are diagonal positive definite;

(ii) \( (\lambda \mathbf{I}^T + \mathbf{k}) \mathbf{P} \mathbf{I} - (1/4) \mathbf{I}_n > 0, \) where \( \mathbf{I} = \mathbf{I}_n + \gamma (\mathbf{L} \otimes \mathbf{I}_3) \);

(iii) the matrix \( \gamma \) is diagonal positive definite and small enough.

Then the position tracking error, the velocity error and their synchronization error, approach zero asymptotically; that is, these vessels can realize the coordination formation asymptotically.

Proof. Define the first Lyapunov function as

\[
V_1 = \frac{1}{2} z_1^T \mathbf{z}_1.
\]

Differentiating \( V_1 \) with respect to time, then we have

\[
\dot{V}_1 = -z_1^T \lambda z_1 + z_1^T \mathbf{z}_2.
\]

Define the second Lyapunov function as

\[
V_2 = V_1 + \frac{1}{2} s^T s.
\]

Take the time derivative of the above equation as

\[
\dot{V}_2 = \dot{V}_1 + s^T \dot{s}
\]

\[
= \dot{V}_1 + s^T (k \mathbf{z}_1 + s^T (\mathbf{I}_n + \gamma (\mathbf{L} \otimes \mathbf{I}_3)) \mathbf{z}_2
\]

\[
= z_1^T \mathbf{z}_1 - z_1^T \lambda z_1 + s^T \mathbf{k} (z_2 - \lambda z_2) + s^T (\mathbf{I}_n + \gamma (\mathbf{L} \otimes \mathbf{I}_3)) \mathbf{M}_n^{-1} (\mathbf{z}_2)
\]

\[
= [\mathbf{r} - \mathbf{M}_n (\mathbf{z}_2) - \mathbf{M}_n (\mathbf{z}_2) \mathbf{I} + \mathbf{M}_n (\mathbf{z}_2) \lambda \mathbf{z}_1 - (\mathbf{C} (\mathbf{z}_2) + \mathbf{D}_n (\mathbf{z}_2)) \mathbf{D}_n (\mathbf{z}_2) - \mathbf{D}_n (\mathbf{z}_2)]
\]

With the control input (26) (27), we can obtain that

\[
\dot{V}_2 = -z_1^T \lambda \mathbf{z}_1 + z_1^T \mathbf{z}_2 - s^T \mathbf{k} (\mathbf{s} + s \mathbf{P})
\]

\[
= -z_1^T \lambda \mathbf{z}_1 + z_1^T \mathbf{z}_2 - s^T \mathbf{k} \mathbf{s} - s^T \mathbf{P} s \text{ sign}(s)
\]

\[
= -z_1^T \lambda \mathbf{z}_1 + z_1^T \mathbf{z}_2 - s^T \mathbf{k} \mathbf{s} - \frac{3n}{2} \sum_{r=1}^n \beta_r |s_r|,
\]

where \(|s_r|\) denotes the absolute value of the variable of \( s_r \).

If we define \( \Gamma = \mathbf{I}_n + \gamma (\mathbf{L} \otimes \mathbf{I}_3) \), then we choose matrix \( \mathbf{Q} \) as

\[
\mathbf{Q} = \begin{bmatrix}
\lambda + k^T \mathbf{P} \mathbf{k} & \mathbf{k}^T \mathbf{P} - \frac{1}{2} \mathbf{I}_n \\
\mathbf{P}^T \mathbf{P} \mathbf{k} & \mathbf{P} \mathbf{I} + \frac{1}{2} \mathbf{I}_n
\end{bmatrix}
\]

If we define \( z = [z_1^T, z_2^T]^T \), then we can obtain that

\[
z^T \mathbf{Q} z = \begin{bmatrix}
z_1^T & z_2^T
\end{bmatrix}
\begin{bmatrix}
\lambda + k^T \mathbf{P} \mathbf{k} & \mathbf{k}^T \mathbf{P} - \frac{1}{2} \mathbf{I}_n \\
\mathbf{P}^T \mathbf{P} \mathbf{k} & \mathbf{P} \mathbf{I} + \frac{1}{2} \mathbf{I}_n
\end{bmatrix}
\begin{bmatrix}
z_1 \\
z_2
\end{bmatrix}
\]

\[
= \left( \mathbf{z}_1^T \lambda + \mathbf{z}_1^T \mathbf{k} \mathbf{P} \mathbf{k} + \mathbf{z}_2^T \mathbf{P} \mathbf{P} \mathbf{k} - \frac{1}{2} \mathbf{z}_1^T \mathbf{I}_n \right)
\times \left( \mathbf{z}_1^T \mathbf{k} \mathbf{P} - \frac{1}{2} \mathbf{z}_1^T \mathbf{I}_n + \mathbf{z}_2^T \mathbf{P} \mathbf{P} \mathbf{k} \right)
\]

\[
= \mathbf{z}_1^T \lambda \mathbf{z}_1 + \mathbf{z}_1^T \mathbf{k} \mathbf{P} \mathbf{k} - \frac{1}{2} \mathbf{z}_1^T \mathbf{I}_n + \mathbf{z}_2^T \mathbf{P} \mathbf{P} \mathbf{k} \mathbf{z}_2
\]

\[
+ \frac{1}{2} \mathbf{z}_1^T \mathbf{z}_1 + \mathbf{z}_1^T \mathbf{k} \mathbf{P} \mathbf{z}_2
\]

\[
= \mathbf{z}_1^T \lambda \mathbf{z}_1 + \mathbf{z}_1^T \mathbf{z}_2 + \mathbf{z}_2^T \mathbf{P} \mathbf{z}_2.
\]

Then (36) can be written as

\[
\dot{V}_2 = -z^T \mathbf{Q} z - \sum_{r=1}^{3n} \beta_r |s_r| \leq 0.
\]

If we choose the matrix \( \gamma \) as small enough, then \( \Gamma \) will be positive definite. All the matrices \( \lambda, \mathbf{P}, \) and \( \mathbf{k} \) are diagonal positive definite, if they are chosen to satisfy \( (\lambda \mathbf{I}^T + \mathbf{k}) \mathbf{P} \mathbf{I} - (1/4) \mathbf{I}_n > 0; \) then we can guarantee that the matrix \( \mathbf{Q} \) is positive definite. If we define \( W(t) = z^T \mathbf{Q} z + \sum_{r=1}^{3n} \beta_r |s_r|, \) it is obvious that the bounded limit of \( W(t) \) exists. From the front definition, we can know that \( z_1, z_2, \) and \( s \) are bounded. With (16), we can know that \( z_1 \) is bounded. In terms of (22), (26), (27), \( z_2 \) is bounded. Then \( z \) and \( s \) are bounded. Due to the definition of \( s, s \) and \( s \) are bounded. Then we can get that \( W(t) \) is also bounded; then \( W(t) \) is uniformly continuous. With Barbalats lemma, \( W(t) \rightarrow 0 \) as \( t \rightarrow \infty \). Then \( z_1 \rightarrow 0, \)

\[
z_2 \rightarrow 0, \quad s \rightarrow 0 \text{ as } t \rightarrow \infty.
\]

With (23), we can get e \( \rightarrow 0 \). Then the synchronization error for each vessel is

\[
e_{ij} = \sum_{j=1}^{n} a_{ij} (z_{ij} - z_{2j}) \rightarrow 0.
\]

Because \( a_{ij} \) is constant, then we can obtain that \( z_{2j}(t) - z_{ij}(t) \rightarrow 0. \)

Though the following calculation

\[
z_{2i}(t) - z_{ij}(t) = z_{2i} - \lambda_i z_{ij} - \lambda_i z_{ij} - \lambda_i z_{ij}
\]

\[
= (\dot{x}_i - \dot{\eta}_d) + \lambda_i (x_i - \eta_d)
\]

\[
- (\dot{x}_j - \dot{\eta}_d) - \lambda_i (x_j - \eta_d)
\]

\[
= (\dot{x}_i - \dot{\eta}_d) + \lambda_i (x_i - x_j)
\]

\[
e_{ij} = (x_i - x_j)
\]

where \( e_{i} = x_i - x_j \). From the above equation, we can know that it is a linear exponential system with the input as \( z_{2j}(t) - z_{ij}(t), \) and \( z_{2j}(t) - z_{ij}(t) \rightarrow 0, \) and \( e_{ij} \) is bounded; then we can obtain that \( \lim_{t \rightarrow \infty} \|e_{ij}\| = 0; \) that is \( x_i \rightarrow x_j \). According to \( z_{ij}(t) \rightarrow 0, \) then \( x_i \rightarrow \eta_d \rightarrow 0. \) Finally, we can know that \( x_1 = \cdots = x_n = \cdots = x_n = \eta_d . \) So the group of vessels achieve the coordinated tracking while holding the desired formation.
4. Robust Formation Controller Design

In this section, we will design the robust coordinated controller for multiple vessels in the presence of external disturbances. This section will be divided into two parts. The first part is that the upper bounded of the disturbance is known in advance. The second part is that the upper bounded is unknown. For the second part, the adaptive control law is designed to estimate the external disturbances. In this section, for a vector $x \in \mathbb{R}^{n \times 1}$, the absolute value of the vector is denoted as $|x| = [(|x_1|, \ldots, |x_n|)]^T$.

If the external disturbance for each vessel is bounded and the upper bounded satisfy $|\tau_d| \leq \tilde{F}$, where $\tilde{F} \in \mathbb{R}^{3 \times 1}$ is a positive constant vector, and for multiple vessels, the vector form is $|\tau_d| \leq \tilde{F}$. If we choose the control input as

$$\tau = \tau_{eq} + \tau_{sw} + \tau_{en},$$

where $\tau_{eq}$ and $\tau_{sw}$ are the same with the definition in the front section and $\tau_{en}$ is the control input to compensate for the external disturbances, the detailed representation is

$$\tau_{en} = -[\tilde{F}_i \text{sign}(s_1) \cdots \tilde{F}_{3n} \text{sign}(s_{3n})]^T = -\tilde{F}.$$

For each vessel, the control input to compensate the external disturbance is as follows

$$\tau_{en}^i = -\tilde{F}_i \in \mathbb{R}^{3 \times 1}.$$

Theorem 5. Consider $n$ vessels to perform the coordination formation task, the vessel model is described as (3) and (4), with the distributed coordinated formation control law (42), (27), and (43), and the conditions in Theorem 4 are satisfied, then the position tracking error, the velocity tracking error, and their synchronization error, are asymptotically stable; that is, these vessels can realize the coordination formation asymptotically.

Proof. The proof procedure in this section is similar to the front section. The main difference is that the external disturbances are considered in this section.

Define the same Lyapunov function with the front section as

$$V_2 = V_1 + \frac{1}{2} s^T s.$$

Taking the time derivative of the above equation as

$$V_2 = V_1 + s^T \dot{s}$$

$$= V_1 + s^T k \dot{z}_i + s^T (I_{3n} + y (L \otimes I_3)) \dot{z}_2$$

$$= z_2^T \dot{z}_2 - z_1^T \lambda z_1 + s^T k (z_2 - \lambda z_1)$$

$$+ s^T (I_{3n} + y (L \otimes I_3)) M^{-1}_h (\eta)$$

$$\times [\tau + \tau_d - M_{n}(\eta) \dot{\eta}_D + M_{n}(\eta) \dot{\hat{f}} + M_{n}(\eta) \lambda \dot{z}_1$$

$$- (C_{n}(\eta, \eta) + D_{n}(\eta, \eta))(\eta_D - \hat{f})$$

$$- (C_{n}(\eta, \eta) + D_{n}(\eta, \eta))(\dot{z}_2 - \lambda z_1)];$$

with the control input (42), (27), and (43) yield:

$$V_2 = -z_i^T \lambda z_i + z_i^T z_2 - s^T P (s + \beta \text{sign}(s))$$

$$+ s^T (I_{3n} + y (L \otimes I_3)) M^{-1}_n (\eta) (\tau_d - \tilde{F})$$

$$\leq -z_i^T \lambda z_i + z_i^T z_2 - s^T P s - \sum_{r=1}^{3n} p_r \beta_r |s_r|$$

$$+ |s| (I_{3n} + y (L \otimes I_3)) M^{-1}_n (\eta) (\tau_d - \tilde{F})$$

$$\leq -z_i^T \lambda z_i + z_i^T z_2 - s^T P s - \sum_{r=1}^{3n} p_r \beta_r |s_r|.$$

From the above inequality, we can see that the same results with the front section are achieved; then we can prove that the position tracking error, velocity tracking error, and their synchronization error are asymptotically stable according to the proof procedure in the front section.

If the external disturbances are unknown in advance, and we assume that the external disturbances vary slowly; that is $\dot{\tau}_d = 0$, then we adopt the adaptive control to estimate the disturbances. Then control law also includes three parts, which is written as

$$\tau = \tau_{eq} + \tau_{sw} + \tau_{en},$$

where

$$\tau_{en} = -\tilde{\tau}_d,$$

and $\tilde{\tau}_d$ is the estimate value of the external disturbances. The adaptive control law is chosen as follows

$$\tilde{\tau}_d = \sigma M_{n}(I_{3n} + y (L \otimes I_3))^{-1} s,$$

where $\sigma$ is a positive real number.

Theorem 6. Consider a group of $n$ vessels to perform the coordination formation task, the vessel model is described as (3) and (4). With the coordinated formation control law (42), (27), and (49), and the adaptive control law (50) and the conditions in the Theorem 4 are satisfied, then the position tracking error, the velocity tracking error, and their synchronization error are asymptotically stable; that is, these vessels can realize the coordination formation asymptotically.

Proof. Define the new Lyapunov function as

$$V_1 = V_2 + \frac{1}{2} \tilde{\tau}_d^T \tilde{\tau}_d,$$

where

$$V_3 = V_1 + s^T \dot{s} + \frac{1}{2} \tilde{\tau}_d^T \tilde{\tau}_d$$

$$= z_i^T \dot{z}_2 - z_i^T \lambda z_i + s^T k \dot{z}_i$$

$$+ s^T (I_{3n} + y (L \otimes I_3)) \dot{z}_2 - \frac{1}{\sigma} \tilde{\tau}_d^T \tilde{\tau}_d.$$
\[ z^T_1 z_2 - z^T_2 \lambda z_1 + s^T k (z_2 - \lambda z_1) + s^T (I_{3n} + \gamma (L \otimes I_3)) M^{-1}_n (\eta) \times [\sigma \ddot{\eta} + \dot{\sigma} M_n (\eta) L (\eta) + M_n (\eta) \lambda \dot{z}_1] \]

\[ - (C_n (\eta, \dot{\eta}) + D_n (\eta, \ddot{\eta})) (\ddot{\eta} - \dot{f}) - (C_n (\eta, \dot{\eta}) + D_n (\eta, \ddot{\eta})) (z_2 - \lambda z_1)] \]

\[ - \frac{1}{\sigma} \ddot{\sigma} \ddot{\eta} \]

\[ = -z^T_1 \lambda z_1 + z^T_1 z_2 - s^T P (s + \beta \text{sign}(s)) \]

\[ - \frac{1}{\sigma} \ddot{\sigma} \ddot{\eta} - \sigma M_n (\eta) (I_{3n} + \gamma (L \otimes I_3))^{-1} s \]

\[ = -z^T_1 \lambda z_1 + z^T_1 z_2 - s^T P (s + \beta \text{sign}(s)) \]

\[ = -z^T_1 \lambda z_1 + z^T_1 z_2 - s^T P s - \frac{2}{\sigma} \sum_{r=1}^{3n} P_r r \beta_r |s_r| . \] (52)

From the above equality, we can see that the same results with the front section are achieved; then we can prove that the position tracking error, velocity tracking error and their synchronization error, are asymptotically stable according to the proof procedure in the front section.

5. Simulation Results

In this section, experimental simulations are carried out to evaluate the effectiveness of the proposed coordinated formation control algorithm. Five marine vessels are considered to perform the coordinated tracking task. Detailed parameters of these vessels are presented in [12]. The proposed algorithm has achieved the leaderless coordination based on the graph theory. In this experiment, the topology graph of communication among these five vessels is chosen as Figure 1.

And the Laplacian matrix of the communication topology graph is as follows

\[ L = \begin{bmatrix}
1 & 0 & 0 & 0 & -1 \\
0 & -1 & 1 & 0 & 0 \\
-1 & 0 & -1 & 1 & 0 \\
0 & -1 & 0 & 1 & 0 \\
0 & 0 & -1 & -1 & 1
\end{bmatrix} . \] (53)

The initial positions of the five vessels are \( \eta_1 = [-80 \ 800 \ -2 \pi/30]^T, \eta_2 = [-50 \ 800 \ -\pi/3]^T, \eta_3 = [-100 \ 780 \ -\pi/4]^T, \eta_4 = [20 \ 830 \ -\pi/2]^T, \) and \( \eta_5 = [-100 \ 800 \ -\pi/4]^T, \) respectively. In order to evaluate the performance of the coordinated tracking, the desired formation pattern of the coordinated formation controller is described by \( \mathbf{I}_1 = [0 \ 0 \ 0 \ 0 \ 0]^T, \mathbf{I}_2 = [0 \ 50 \ 0 \ 0 \ 0]^T, \mathbf{I}_3 = [0 \ -50 \ 0 \ 0 \ 0]^T, \mathbf{I}_4 = [0 \ 100 \ 0 \ 0 \ 0]^T, \) and \( \mathbf{I}_5 = [0 \ -100 \ 0 \ 0 \ 0]^T . \) The desired trajectory for all the formation points is chosen as \( \eta_d(t) = [\eta_d \ e_d \ \psi_d]^T , \) and the detailed forms are \( \eta_d = t, e_d = 800 - 800 \sin(t/400), \) and \( \psi_d = \arctan(e_d/\eta_d) . \)

![Figure 1: The communication topology graph of these vessels.](image)

![Figure 2: The formation trajectories in horizontal plane.](image)

Although the proposed coordination algorithm is robust to unknown external disturbance, the disturbance model in the simulation can be chosen as a fixed term instead of the unknown disturbance. We assume that the vessels encounter the wind, wave, and current. And the wind is assumed to be fixed direction and fixed velocity; then the disturbance of wind is a constant; the wave and current is assumed to be the sine wave with a fixed frequency at one time. So the external disturbances can be chosen as

\[ r_{di} = 10^6 \cdot \begin{bmatrix}
0.05 \sin \left( \frac{\pi t}{100} \right) + 0.02, & 0.03 \sin \left( \frac{\pi t}{100} \right) \\
0.01 \sin \left( \frac{\pi t}{100} \right) + 0.01 \end{bmatrix}^T (N) . \] (54)

The control parameters of the coordinated formation controller are chosen as \( \lambda = \text{diag}(0.05, 0.05, 0.2), \eta_l = \text{diag}(1, 1, 1), \mathbf{P}_1 = \text{diag}(0.3, 0.3, 0.15), \) and \( \beta_l = \text{diag}(1, 1, 0.5) . \)

The simulation results are shown from Figure 2 to Figure 9. Figure 2 shows the movements for these vessels in the plane. The heading change curve of each vessel is shown in Figure 3. Figures 4, 5, and 6 show the surge velocity, the sway velocity, and the angular velocity of each vessel during the coordinated control process, respectively. Figures 7, 8, and 9
show the surge force, sway forces, and the heave torques applied to the vessels, respectively.

We can see that these vessels realized the coordinated tracking task from Figures 2 and 3. From Figures 4, 5, and 6, the velocities of these vessels achieve consensus as a whole, and the velocities cannot achieve consensus when the vessels move to the inflexion of the respective path curve. The phenomenon of the surge velocity is obvious in the experimental simulations due to the vessels move along the tangent directions of the desired trajectory. This phenomenon appears as a result of vessel speed regulated to maintain the desired formation pattern at the inflexion of the respective path curve. From Figures 7, 8, and 9, we know that the forces and torques for the group of \( n \) vessels approach consensus, in a way. This is the result of that these vessels are uniform in these experimental simulations. With the analysis of the simulation results, we can conclude that these vessels can accomplish coordinated trajectory tracking task while keeping the desired formation. It means that the proposed coordination control algorithm is effective.

6. Conclusion

This paper has proposed a new backstepping sliding mode coordinated formation control algorithm for multiple surface vessels in the presence of external environmental disturbances. The proposed coordinated formation controller for these vessels is designed by defining a new switched function. And a new cross-coupling error is defined using the velocity error and velocity synchronization error to be applicable
for the backstepping sliding mode controller. In addition, the adaptive control law is also designed to compensate for the external disturbances and then achieve the robustness. Finally, the effectiveness of the proposed coordination control algorithm is demonstrated by experimental simulations.
