We will give the α -Lipschitz version of the Banach-Stone type theorems for lattice-valued α -Lipschitz functions on some metric spaces. In particular, when X and Y are bounded metric spaces, if $T : \text{Lip}(X) \rightarrow \text{Lip}(Y)$ is a nonvanishing preserver, then T is a weighted composition operator $Tf = h \cdot f \circ \varphi$, where $\varphi : Y \rightarrow X$ is a Lipschitz homeomorphism. We also characterize the compact weighted composition operators between spaces of Lipschitz functions.

1. Introduction

The classical Banach-Stone theorem tells us that, when X and Y are compact Hausdorff spaces, every linear surjective isometry from $C(X)$ onto $C(Y)$ can be written as a weighted composition operator; that is, it is of the form

$$(Tf)(y) = J(y) f(\varphi(y)), \quad (1)$$

where φ is a homeomorphism from Y onto X and $J \in C(Y)$ with $|J(y)| = 1$ for all $y \in Y$. The theorem has many variable extensions concerning isometries, algebra isomorphisms, and disjointness preserving mappings between continuous function spaces; and we refer the surveys [1, 2] for more history about Banach-Stone theorems. Moreover, Kamowitz [3] gave the representation and spectrum of the compact weighted composition operators on the continuous functions.

Cao et al. stated a lattice version of the classical Banach-Stone theorem in [4]. Later, Chen et al. [5], Ercan and Önal [6, 7], and Miao et al. [8] generalized this result. When X, Y are compact Hausdorff spaces and E, F are Banach lattices, by the main results of [5, 7], we can see that every vector lattice isomorphism T from $C(X, E)$ onto $C(Y, F)$ preserving the nonvanishing functions must be a weighted composition operator.

Garrido and Jaramillo [9, 10] and Weaver [11] tackled the Banach-Stone type theorem for lattices of real Lipschitz functions. Later, Jiménez-Vargas and Villegas-Vallecillos [12] proved that two little Lipschitz algebras are order isomorphic if and only if the corresponding compact metric spaces are Lipschitz homeomorphic. Recently, Jiménez-Vargas et al. [13] presented a Lipschitz version of the result in [5], in which the underlying spaces should be compact.

Our first goal of this paper is to prove the Banach-Stone type theorem in the setting of lattice-valued α -Lipschitz functions. Section 2 is devoted to the preliminaries about vector lattices and α -Lipschitz functions. Then we will give the α -Lipschitz version of Banach-Stone theorem in Section 3. In particular, when X, Y are bounded metric spaces, if $T : \text{Lip}(X) \rightarrow \text{Lip}(Y)$ is a nonvanishing preserver, then we will show that T is a weighted composition operator $Tf = h \cdot f \circ \varphi$, where $\varphi : Y \rightarrow X$ is a Lipschitz homeomorphism. Our second aim is to give the characterization of compact weighted composition operators on the α -Lipschitz functions.

2. Preliminaries

An ordered vector space E is said to be a *vector lattice* if $\max\{x, y\}$ exists for any x, y in E . A vector lattice E is said

to be a *Banach lattice* if it is complete under its norm $\|\cdot\|$ and satisfies the Riesz law:

$$|x| \leq |y| \implies \|x\| \leq \|y\|, \quad (2)$$

where $|x| = \max\{x, -x\}$.

Let (X, d) be a metric space and E a Banach space; if $0 < \alpha \leq 1$, a function f from X to E is said to be α -Lipschitz if

$$L_\alpha(f) = \sup \left\{ \frac{\|f(x) - f(y)\|}{d^\alpha(x, y)} : x, y \in X, x \neq y \right\} < \infty. \quad (3)$$

The α -Lipschitz function space $\text{Lip}_\alpha(X, E)$ is the space of all E -valued α -Lipschitz functions on X . $\text{Lip}_\alpha^b(X, E)$ is the Banach space of all bounded α -Lipschitz functions $f : X \rightarrow E$ with the α -Lipschitz norm

$$\|f\| = \max\{L_\alpha(f), \|f\|_\infty\}, \quad (4)$$

where $\|f\|_\infty = \sup\{\|f(x)\| : x \in X\}$. Furthermore, the *little Lipschitz space* $\text{lip}_\alpha(X, E)$ is then defined to be the closed subspace of $\text{Lip}_\alpha(X, E)$ of these functions f with the following property: for every $\varepsilon > 0$, there exists $\delta > 0$ such that $\|f(x_1) - f(x_2)\| < \varepsilon d^\alpha(x_1, x_2)$ whenever $d(x_1, x_2) \leq \delta$. $\text{lip}_\alpha^b(X, E)$ is the subspace of $\text{lip}_\alpha(X, E)$ consisting of all bounded functions. Notice that when $\alpha = 1$, $\text{Lip}_\alpha(X, E)$ is just Lipschitz space $\text{Lip}(X, E)$. Moreover, if E is a Banach lattice, then $\text{Lip}_\alpha(X, E)$ is a vector lattice with the usual pointwise order

$$f \leq g \iff f(x) \leq g(x), \quad \forall x \in X. \quad (5)$$

However, $\text{Lip}_\alpha^b(X, E)$ is not a Banach lattice since $\|\cdot\|$ does not satisfy the Riesz law in general.

A mapping φ from Y to X is said to be a α -Lipschitz homeomorphism if it is bijective and φ and φ^{-1} are both α -Lipschitz. If f is in $\text{Lip}_\alpha(X)$ and e is a vector in E , denote by $f \otimes e$ the function $x \mapsto f(x)e$ in $\text{Lip}_\alpha(X, E)$. In particular, $1 \otimes e$ denotes the constant function $x \mapsto e$ on X . For any function f in $\text{Lip}_\alpha(X, E)$, the zero set $\{x \in X : f(x) = 0\}$ of f is denoted by $z(f)$ and its cozero set $\{x \in X : f(x) \neq 0\}$ is $\text{coz}(f)$, and f is said to be *nonvanishing* if $z(f) = \emptyset$. An operator $T : \text{Lip}_\alpha(X, E) \rightarrow \text{Lip}_\alpha(Y, F)$ is said to be a *nonvanishing preserver* if

$$z(f) = \emptyset \iff z(Tf) = \emptyset, \quad \forall f \in \text{Lip}_\alpha(X, E). \quad (6)$$

T is said to be a *Riesz isomorphism* if $T(f \vee g) = Tf \vee Tg$ and $T(f \wedge g) = Tf \wedge Tg$ for any $f, g \in \text{Lip}_\alpha(X, E)$.

3. Nonvanishing Preservers on Lipschitz Functions

In this section, our results will be valid (with the same proof) for different kinds of spaces. For this reason we first consider several situations to work in. Throughout this section we will assume that $0 < \alpha \leq 1$, X, Y are metric spaces and E, F are Banach lattices.

Context 1. $A(X, E) = \text{Lip}_\alpha^b(X, E)$, $A(Y, F) = \text{Lip}_\alpha^b(Y, F)$.

Context 2 ($0 < \alpha < 1$). $A(X, E) = \text{lip}_\alpha^b(X, E)$, $A(Y, F) = \text{lip}_\alpha^b(Y, F)$.

This means that when we refer to $X, Y, A(X, E), A(Y, F)$, we assume that all of them are included at the same time in one of the above two contexts.

Suppose that X is a metric space and $0 < \alpha \leq 1$, for any $x_1 \neq x_2 \in X$, the function

$$f(x) = \max \left\{ 0, 1 - \frac{d^\alpha(x, x_2)}{d^\alpha(x_1, x_2)} \right\} \quad (7)$$

belongs to $\text{Lip}_\alpha^b(X)$. Moreover, if $0 < \alpha < 1$, then we can find $\beta > 0$ such that $\alpha < \beta < 1$, and the function

$$f(x) = \max \left\{ 0, 1 - \frac{d^\beta(x, x_2)}{d^\beta(x_1, x_2)} \right\} \quad (8)$$

belongs to $\text{lip}_\alpha^b(X)$. The function f defined in (7) or (8) has the property: $0 \leq f \leq 1$, $f(x_1) = 0$, $f(x_2) = 1$ and $z(f) = \{x \in X : d(x, x_2) \geq d(x_1, x_2)\}$.

Theorem 1. Let $T : A(X, E) \rightarrow A(Y, F)$ be a Riesz isomorphism preserving nonvanishing functions. Then T carries the form

$$(Tf)(y) = (Jy) f(\varphi(y)), \quad \forall f \in A(X, E), y \in Y. \quad (9)$$

Here, φ is a homeomorphism from Y onto X and all fiber linear maps $Jy : E \rightarrow F$ are isomorphisms.

Remark 2. When $\alpha = 1$, the previous theorem is not valid for the little Lipschitz space $\text{lip}_1(X, E)$, where X is a connected Banach and E is a Banach lattice. Note that if X is a connected Banach spaces, we have that $\text{lip}_1^b(X, E) = \text{lip}_1(X, E)$ consisting of all E -valued constant functions defined on X . Let φ be any map from $\mathbb{R}^2$ to $\mathbb{R}$ and $T : \text{lip}_1(\mathbb{R}, E) \rightarrow \text{lip}_1(\mathbb{R}^2, E)$ a linear bijection operator defined by

$$Tf(y) = f(\varphi(y)), \quad \forall y \in \mathbb{R}^2. \quad (10)$$

It is obvious that the operator T is a Riesz isomorphism preserving nonvanishing functions with a weighted composition representation, but $\mathbb{R}$ and $\mathbb{R}^2$ are not homeomorphic.

It is easy to prove the following lemma.

Lemma 3. T preserves common zeros, that is,

$$\bigcap_{i=1}^n z(f_i) \neq \emptyset \iff \bigcap_{i=1}^n z(Tf_i) \neq \emptyset \quad (11)$$

for any $f_1, \dots, f_n \in A(X, E)$ and $n \in \mathbb{N}$.

Proof of Theorem 1. In the above contexts, $A(X, E)$ and $A(Y, F)$ contain constant functions, so $E_y = E$ and $F_y = F$, where E_y, F_y are defined in [14, Definition 3.8]. Therefore, by [14, Theorem 3.1] we can derive the result. $\square$

Lemma 4. In the Contexts 1 and 2, T is automatically continuous.

Proof. We are going to use the Closed Graph Theorem to prove this lemma. Suppose that the sequence of functions $\{f_n\}$ converges to f_0 in $A(X, E)$ and $\{Tf_n\}$ converges to g_0 in $A(Y, F)$; then for any $x \in X$ and $y \in Y$, we have that $\{f_n(x)\}$ converges to $f_0(x)$ in E and $\{(Tf_n)(y)\}$ converges to $g_0(y)$ in F , respectively. Notice that, for any $x \in X$, $J\varphi^{-1}(x) : E \rightarrow F$ is continuous; then one can derive that

$$\begin{aligned} (Tf_n)(\varphi^{-1}(x)) &= (J\varphi^{-1}(x))f_n(x) \longrightarrow (J\varphi^{-1}(x))f_0(x) \\ &= (Tf_0)(\varphi^{-1}(x)) \end{aligned} \quad (12)$$

for all x in X . Since φ is a bijection from Y onto X , we get that the sequence $\{(Tf_n)(y)\}$ converges to $(Tf_0)(y)$ for all y in Y , and hence $g_0 = Tf_0$. This means that T is a closed operator from $A(X, E)$ to $A(Y, F)$, and then T is continuous. $\square$

In order to prove that φ is a α -Lipschitz map from Y onto X , we need the following lemma, and some idea of the proof comes from [15, Lemma 5.8].

Lemma 5. *For any fixed element $e \in E$ with $\|e\| = 1$, we have that*

$$\inf_{y \in Y} \|(Jy)(e)\| = \inf_{y \in Y} \|T(1 \otimes e)(y)\| > 0. \quad (13)$$

Proof. By Theorem 1 we can also find a map $\tilde{J}$ from X to $\text{Iso}(F, E)$ (which is the set of all linear isomorphisms from F to E) and a bijection $\tilde{\varphi}$ from X onto Y such that

$$(T^{-1}g)(x) = (\tilde{J}x)g(\tilde{\varphi}(x)) \quad (14)$$

for all $x \in X$ and $g \in A(Y, F)$. From the definition of ψ , φ , and $\tilde{\varphi}$, we can see that $\varphi^{-1} = \tilde{\varphi} \circ \psi$.

Suppose on the contrary that there exists a sequence $\{y_n\} \subset Y$ such that $\|T(1 \otimes e)(y_n)\| = \|(Jy_n)(e)\| \leq 2^{-2n}$ for all $n \in \mathbb{N}$. If $\{y_n\}$ has a limit point y' in Y , notice that T preserves nonvanishing functions, then we can see that $(Jy')(e) = 0$ and hence $e = 0$. This leads to a contradiction. On the other hand, if there exists a positive scalar $\tau > 0$ such that $d^\alpha(y_n, y_m) \geq \tau$ for any $n, m \in \mathbb{N}$ with $n \neq m$, when we take the norm one element

$$b_n = \frac{T(1 \otimes e)(y_n)}{\|T(1 \otimes e)(y_n)\|}, \quad (15)$$

then we can derive that

$$[T^{-1}(T(1 \otimes e))](\varphi(y_n)) = (1 \otimes e)(\varphi(y_n)) = e, \quad (16)$$

$$[T^{-1}(T(1 \otimes e))](\varphi(y_n)) = (\tilde{J}\varphi(y_n))T(1 \otimes e)(y_n)$$

for all $n \in \mathbb{N}$. Therefore, for any $n \in \mathbb{N}$, we know that

$$\begin{aligned} \|(\tilde{J}\varphi(y_n))(b_n)\| &= \frac{\|(\tilde{J}\varphi(y_n))T(1 \otimes e)(y_n)\|}{\|T(1 \otimes e)(y_n)\|} \\ &= \frac{1}{\|T(1 \otimes e)(y_n)\|} \geq 2^{2n}. \end{aligned} \quad (17)$$

Moreover, for any $n \in \mathbb{N}$, by the similar manner of (7) and (8) we can define the function $\psi_n(y) \in A^b(Y)$ such that $0 \leq \psi_n \leq 1$, $L_\alpha(\psi_n) \leq m$ for some $m > 0$, $\psi_n(y_n) = 1$ and $\psi_n(y) = 0$ for all y such that $d(y, y_n) \geq \tau/2$. When put

$$h_0 = \sum_{n=2}^{\infty} \frac{\psi_n \otimes b_n}{2^n}, \quad (18)$$

we can see that h_0 belongs to $A^b(Y, F)$ and $h_0(y_n) = b_n/2^n$ for $n > 1$. Then one can conclude that

$$\begin{aligned} (T^{-1}h_0)(\varphi(y_n)) &= (\tilde{J}\varphi(y_n))(h_0[\tilde{\varphi}(\varphi(y_n))]) \\ &= (\tilde{J}\varphi(y_n))(h_0(y_n)) = \frac{1}{2^n}(\tilde{J}\varphi(y_n))(b_n), \end{aligned} \quad (19)$$

and hence

$$\|(T^{-1}h_0)(\varphi(y_n))\| = \frac{\|(\tilde{J}\varphi(y_n))(b_n)\|}{2^n} > 2^n, \quad \forall n \geq 2. \quad (20)$$

This is a contradiction in Contexts 1 and 2 since $\|T^{-1}h_0\|_\infty < \infty$. $\square$

Theorem 6. *Suppose that X, Y are bounded metric spaces in the Contexts 1 and 2; then φ is a α -Lipschitz map from Y onto X .*

Proof. We can define the linear map $\tilde{T}$ from $A(X)$ to $A(Y)$ by

$$(\tilde{T}f)(y) = f(\varphi(y)), \quad \forall y \in Y. \quad (21)$$

We have to show that $\tilde{T}$ is well defined at first. For any fixed element $e \in E$ with $\|e\| = 1$, from Lemma 5 we can choose a positive scalar ν such that $\|T(1 \otimes e)(y)\| \geq \nu > 0$ for all y in Y , and then it is easy to see that the function h which maps y to $1/\|T(1 \otimes e)(y)\|$ belongs to $A(Y)$.

Assume that f is a positive function in $A(X)$; one can get that, for any $y_1, y_2 \in Y$,

$$\begin{aligned} &|(\tilde{T}f)(y_1)\|T(1 \otimes e)(y_1)\| - (\tilde{T}f)(y_2)\|T(1 \otimes e)(y_2)\|| \\ &= \| (Jy_1)f(\varphi(y_1))e\| - \| (Jy_2)f(\varphi(y_2))e\| \\ &\leq \| (Jy_1)f(\varphi(y_1))e - (Jy_2)f(\varphi(y_2))e\| \\ &= \|T(f \otimes e)(y_1) - T(f \otimes e)(y_2)\| \\ &\leq L_\alpha(T(f \otimes e))d^\alpha(y_1, y_2) \leq \|T(f \otimes e)\|d^\alpha(y_1, y_2); \end{aligned} \quad (22)$$

that is, $(\tilde{T}f)(y)\|T(1 \otimes e)(y)\|$ is a bounded α -Lipschitz function. Moreover, in Context 2 we can derive that $(\tilde{T}f)(y)\|T(1 \otimes e)(y)\|$ is also a little Lipschitz function. This means that the function $(\tilde{T}f)(y) = (\tilde{T}f)(y)\|T(1 \otimes e)(y)\|h(y)$ belongs to $A(Y)$. Therefore, $\tilde{T}$ is a well-defined bijective linear operator from $A(X)$ onto $A(Y)$, and $\tilde{T}$ is also a nonvanishing preserver.

Suppose that $\{f_n\}$ is a sequence which converges to 0 in $A(X)$ and the sequence $\{\tilde{T}f_n\}$ converges to g_0 in $A(Y)$. For any $n \in \mathbb{N}$ and $y \in Y$, $(\tilde{T}f_n)(y) = f_n(\varphi(y))$, and hence we have that $\{f_n(\varphi(y))\}$ converges to $g_0(y)$ for all $y \in Y$. Notice that $\{f_n\}$ converges to 0; one can conclude that $\{f_n(x)\}$ converges to 0 for all $x \in X$, and, since φ is a bijective map from Y onto X , we have that $g_0(y) = 0$ for any y in Y . Therefore, $\tilde{T}$ is a closed operator and hence $\tilde{T}$ is continuous.

For any y_1 and y_2 in Y , there exists a function $f_0 \in A(X)$ such that $\|f_0\| \leq D(X) + D(X)^{1-\alpha}$ and $f_0(\varphi(y_1)) = d(\varphi(y_1), \varphi(y_2))$ and $f_0(\varphi(y_2)) = 0$ (in fact, $f_0(x) = d(x, \varphi(y_2))$ has the properties that we need). Here $D(X)$ denotes the diameter of X . Then we can derive that

$$\begin{aligned} |(\tilde{T}f_0)(y_1) - (\tilde{T}f_0)(y_2)| &\leq L_\alpha (\tilde{T}f_0) d^\alpha(y_1, y_2) \\ &\leq \|\tilde{T}\| \|f_0\| d^\alpha(y_1, y_2). \end{aligned} \quad (23)$$

Furthermore, we have that

$$\begin{aligned} d(\varphi(y_1), \varphi(y_2)) &= |f_0(\varphi(y_1)) - f_0(\varphi(y_2))| \\ &= |(\tilde{T}f_0)(y_1) - (\tilde{T}f_0)(y_2)| \\ &\leq \|\tilde{T}\| (D(X) + D(X)^{1-\alpha}) d^\alpha(y_1, y_2), \end{aligned} \quad (24)$$

and this means that φ is a α -Lipschitz mapping from Y onto X . Similarly, we can see that φ^{-1} is also α -Lipschitz, and then φ is a α -Lipschitz homeomorphism. $\square$

For the spaces of scalar-valued Lipschitz functions, we give a complete characterization of nonvanishing preservers. But at first we need to recall a special case of [16, Lemma 25].

Lemma 7. *Let $A(X)$, $A(Y)$ be in Contexts 1 and 2. Suppose that $T : A(X) \rightarrow A(Y)$ is a linear nonvanishing preserver; then the map $S : A(X) \rightarrow A(Y)$ given by*

$$Sf = Tf \cdot \frac{T1}{|T1|} \quad (25)$$

is a Riesz isomorphism preserving nonvanishing functions.

Proof. For completeness, we will sketch the proof. Observe that $T1$ is never vanishing. If $f \in A(X)$ and $\lambda \in \mathbb{R}$, then $\lambda \in \text{range } f$ if and only if $0 \in \text{range}(f - \lambda)$ if and only if $0 \in \text{range}(Tf - \lambda T1)$ if and only if $\lambda \in \text{range } Tf/T1$. In particular, if $f \geq 0$, then $Tf/T1 \geq 0$. Let $Y_+ = \{y \in Y : (T1)(y) > 0\}$ and $Y_- = \{y \in Y : (T1)(y) < 0\}$. Then $Y_+ \cup Y_-$ is a partition of Y into two open sets.

Suppose that $f \in A(X)$ and $f \geq 0$. Then $Tf \geq 0$ on Y_+ and $Tf \leq 0$ on Y_- . Hence $Tf \cdot T1/|T1| = |Tf| \in A(Y)$. For any $f \in A(X)$, we have that $f_+, f_- \in A(X)$, and $|T(f_+)| = T(f_+) \cdot T1/|T1|$ and $|T(f_-)| = T(f_-) \cdot T1/|T1|$. Then we can derive that

$$\begin{aligned} Sf &= Tf \cdot \frac{T1}{|T1|} = (T(f_+) - T(f_-)) \cdot \frac{T1}{|T1|} \\ &= |T(f_+)| - |T(f_-)| \in A(Y). \end{aligned} \quad (26)$$

This means that S is well defined. Moreover, it is easy to check that S is bijective.

From the previous paragraph, if $0 \leq f \in A(X)$, then $Sf = |Tf| \geq 0$. If $f \in A(X)$ and $g = Sf \geq 0$, then by the above,

$$0 \leq Sf = Tf \cdot \frac{T1_X}{|T1_X|} = |T(f_+)| - |T(f_-)|. \quad (27)$$

By [17, Lemma 2.3], T is biseparating, and hence $T(f_+) \cdot T(f_-) = 0$. It follows that $T(f_-) = 0$ and thus $f_- = 0$. Therefore, $f \geq 0$. Thus S is a Riesz isomorphism. It is trivial to check that $0 \in \text{range } f$ if $0 \in \text{range } Sf$ for any $f \in A(X)$. $\square$

Theorem 8. *Suppose that X, Y are bounded metric spaces and T is a nonvanishing preserver between the following function spaces:*

- (i) $0 < \alpha \leq 1$ and $T : \text{Lip}_\alpha(X) \rightarrow \text{Lip}_\alpha(Y)$;
- (ii) $0 < \alpha < 1$ and $T : \text{Lip}_\alpha(X) \rightarrow \text{Lip}_\alpha(Y)$.

Then T is a weighted composition operator of the form

$$(Tf)(y) = h(y) f(\varphi(y)). \quad (28)$$

Here $h = T1$ and $\varphi : Y \rightarrow X$ is a α -Lipschitz map.

Proof. By Lemma 7 we have that T is a Riesz isomorphism. Then by Theorem 6 we can derive the conclusion. $\square$

In Theorem 8, the boundedness of the metric spaces can not be dropped.

Example 9. Let $\mathbb{N}_1$ be the positive integers with the discrete metric, and we can derive that $\mathbb{N}_1$ is not Lipschitz homeomorphic to $\mathbb{N}$. By [18, Example 1.6.4] we can derive that $\text{Lip}^b(\mathbb{N}) = \text{Lip}^b(\mathbb{N}_1) = \ell^\infty$, and then the identity map $I : \text{Lip}^b(\mathbb{N}) \rightarrow \text{Lip}^b(\mathbb{N}_1)$ is a nonvanishing preserver. However, the underlying metric spaces are not Lipschitz homeomorphic.

4. Compact Weighted Composition Operators on Lipschitz Spaces

Suppose that X, Y are metric spaces, $0 < \alpha \leq 1$, and $T : \text{Lip}_\alpha^b(X) \rightarrow \text{Lip}_\alpha^b(Y)$ is a weighted composition operator, that is,

$$(Tf)(y) = h(y) f(\varphi(y)), \quad \forall y \in Y, f \in \text{Lip}_\alpha^b(X). \quad (29)$$

Here $h = T1$ and $\varphi : Y \rightarrow X$ is a α -Lipschitz mapping. Put $Y_0 = \{y \in Y : h(y) = 0\}$. Recall that $\varphi : Y \rightarrow X$ is *supercontractive* on $Y' \subset Y$ if for each $\varepsilon > 0$ there exists $\delta > 0$ such that $d(\varphi(y_1), \varphi(y_2)) < \varepsilon d(y_1, y_2)$ whenever $y_1, y_2 \in Y'$ and $0 < d(y_1, y_2) < \delta$. In this section, we will characterize the compact weighted composition operator T and consider its spectrum.

Theorem 10. *Suppose that T is compact. For any $y_0 \in Y \setminus Y_0$, there is an open neighborhood U_0 of y_0 such that φ is supercontractive on U_0 and $\varphi(U_0)$ is totally bounded.*

Proof. Since $h(y_0) \neq 0$, we can find an open neighborhood U_0 of y_0 such that $|h(y)| \geq |h(y_0)|/2 > 0$ for all $y \in U_0$. Suppose on the contrary that there exist $\{x_n\}, \{y_n\} \subset U_0$ such that $d(x_n, y_n) \rightarrow 0$ and

$$\frac{d(\varphi(x_n), \varphi(y_n))}{d(x_n, y_n)} > \varepsilon_0 \quad (30)$$

for some $\varepsilon_0 > 0$. Without loss of generality we can assume that $d^{\alpha^2}(x_n, y_n) < 1/n$.

Let

$$f_n(x) = \frac{1 - e^{-nd^{\alpha}(x, \varphi(y_n))}}{n}; \quad (31)$$

we can derive that $\|f_n\|_{\infty} \leq 1/n$ and $|f_n(x_1) - f_n(x_2)| \leq d^{\alpha}(x_1, x_2)$ for any $x_1, x_2 \in X$. This implies that $\{f_n\}$ is a bounded sequence in $\text{Lip}_{\alpha}^b(X)$. If T is compact, then there exists a subsequence $\{f_{n_k}\}$ such that $Tf_{n_k} \rightarrow g_0 \in \text{Lip}_{\alpha}^b(Y)$. Since $f_n \rightarrow 0$ uniformly, for any $y \in Y$, we have that

$$|(Tf_{n_k})(y)| = |h(y) f_{n_k}(\varphi(y))| \leq \|h\|_{\infty} |f_{n_k}(\varphi(y))| \rightarrow 0, \quad (32)$$

and then $g_0 = 0$. This means that $Tf_{n_k} \rightarrow 0$ in $\text{Lip}_{\alpha}^b(Y)$.

On the other hand, for any $n \in \mathbb{N}$, by the Mean Value Theorem we have that

$$\begin{aligned} \frac{|(Tf_n)(x_n) - (Tf_n)(y_n)|}{d^{\alpha}(x_n, y_n)} &= \frac{|h(x_n) f_n(\varphi(x_n))|}{d^{\alpha}(x_n, y_n)} \\ &\geq \frac{|h(y_0)|}{2} \frac{1 - e^{-nd^{\alpha}(\varphi(x_n), \varphi(y_n))}}{nd^{\alpha}(x_n, y_n)} \\ &= \frac{|h(y_0)|}{2} e^{-n\xi_n} \frac{d^{\alpha}(\varphi(x_n), \varphi(y_n))}{d^{\alpha}(x_n, y_n)} \\ &\geq \frac{|h(y_0)|}{2} e^{-L_{\alpha}^{\alpha}(\varphi)} \varepsilon_0^{\alpha}. \end{aligned} \quad (33)$$

Here $0 < \xi_n < d^{\alpha}(\varphi(x_n), \varphi(y_n)) \leq L_{\alpha}^{\alpha}(\varphi) d^{\alpha^2}(x_n, y_n) < L_{\alpha}^{\alpha}(\varphi)/n$. Therefore, we can derive that $L_{\alpha}(Tf_n) \rightarrow 0$, and this is a contradiction.

On the other hand, suppose on the contrary that $\varphi(U_0)$ is not totally bounded, then there exist a constant $\tau > 0$ and $z_n = \varphi(u_n) \in \varphi(U_0)$ such that $d^{\alpha}(z_n, z_m) > \tau$ whenever $n \neq m$. Let

$$f_n(x) = 1 - e^{-d^{\alpha}(x, z_n)}, \quad \forall x \in X; \quad (34)$$

then it is easy to see that $f_n(z_n) = 0$ and $\|f_n\| \leq 1$. Moreover, for any $n \neq m$, we can derive that

$$\begin{aligned} \|Tf_n - Tf_m\|_{\infty} &\geq |h(u_n) f_m(z_n)| \\ &\geq \frac{|h(y_0)|}{2} (1 - e^{-d^{\alpha}(z_n, z_m)}) \\ &\geq \frac{|h(y_0)|}{2} (1 - e^{-\tau}). \end{aligned} \quad (35)$$

Therefore, $\{Tf_n\}$ has no Cauchy subsequence, and hence T is not compact. This leads to a contradiction. $\square$

Theorem 11. Suppose that φ is supercontractive on $Y \setminus Y_0$ and $\varphi(Y \setminus Y_0)$ is totally bounded; then the weighted composition operator defined by (29) is compact.

Proof. Let $\{f_n\} \subset \text{Lip}_{\alpha}^b(X)$ be a bounded sequence, that is, $\|f_n\| \leq M$ for some $M > 0$. Since $\varphi(Y \setminus Y_0)$ is totally bounded, there exists a subsequence of $\{f_n\}$, which is also denoted by $\{f_n\}$, such that $\{f_n\}$ is convergent uniformly in $\varphi(Y \setminus Y_0)$. Denote the limit by $f_0(x)$ for all $x \in \varphi(Y \setminus Y_0)$. It is easy to verify that f_0 is a bounded Lipschitz function in $\varphi(Y \setminus Y_0)$. By the similar argument of [18, Theorem 1.5.6] we can extend f_0 to be a bounded Lipschitz function in $\text{Lip}_{\alpha}^b(X)$, which is also denoted by f_0 . It suffices to show that $\{Tf_n\}$ converges to Tf_0 in $\text{Lip}_{\alpha}^b(Y)$.

Since T is a weighted composition operator, it is easy to see that $\{Tf_n\}$ converges to Tf_0 uniformly on Y . Let $\varepsilon > 0$ be given. Since φ is supercontractive on $Y \setminus Y_0$, there exists $\delta > 0$ such that

$$\frac{d(\varphi(y_1), \varphi(y_2))}{d(y_1, y_2)} < \varepsilon \quad (36)$$

whenever $y_1, y_2 \in Y \setminus Y_0$ and $0 < d(y_1, y_2) < \delta$.

We will show that $L_{\alpha}(Tf_n - Tf_0) \rightarrow 0$ by dividing into four cases as the following arguments. For any $y_1, y_2 \in Y$ with $y_1 \neq y_2$.

Case 1. If $y_1, y_2 \in Y_0$, we have that $(Tf_n)(y_i) = (Tf_0)(y_i) = 0$ for $i = 1, 2$.

Case 2. If $y_1, y_2 \in Y \setminus Y_0$ and $0 < d(y_1, y_2) < \delta$, we have that

$$\begin{aligned} &|T(f_n - f_0)(y_1) - T(f_n - f_0)(y_2)| \\ &\leq |[h(y_1) - h(y_2)](f_n - f_0)(\varphi(y_1))| \\ &\quad + |h(y_2)[(f_n - f_0)(\varphi(y_1)) - (f_n - f_0)(\varphi(y_2))]| \\ &\leq L_{\alpha}(h) d^{\alpha}(y_1, y_2) |(f_n - f_0)(\varphi(y_1))| \\ &\quad + \|h\|_{\infty} (L_{\alpha}(f_n) + L_{\alpha}(f_0)) d^{\alpha}(\varphi(y_1), \varphi(y_2)). \end{aligned} \quad (37)$$

Moreover, by (36) we can derive that

$$\begin{aligned} d^{\alpha}(\varphi(y_1), \varphi(y_2)) &= \frac{d^{\alpha}(\varphi(y_1), \varphi(y_2))}{d^{\alpha}(y_1, y_2)} d^{\alpha}(y_1, y_2) \\ &\leq \varepsilon^{\alpha} d^{\alpha}(y_1, y_2). \end{aligned} \quad (38)$$

Case 3. If $y_1, y_2 \in Y \setminus Y_0$ and $d(y_1, y_2) > \delta$, we have that

$$\begin{aligned} &\frac{|T(f_n - f_0)(y_1) - T(f_n - f_0)(y_2)|}{d^{\alpha}(y_1, y_2)} \\ &\leq \frac{2\|Tf_n - Tf_0\|_{\infty}}{\delta^{\alpha}}. \end{aligned} \quad (39)$$

Case 4. If $y_1 \in Y \setminus Y_0$ and $y_2 \in Y_0$, we have that $h(y_2) = 0$ and then

$$\begin{aligned} & |T(f_n - f_0)(y_1) - T(f_n - f_0)(y_2)| \\ &= |h(y_1)(f_n - f_0)(\varphi(y_1))| \\ &= |h(y_1) - h(y_2)| \cdot |(f_n - f_0)(\varphi(y_1))| \\ &\leq L_\alpha(h) d^\alpha(y_1, y_2) |(f_n - f_0)(\varphi(y_1))|. \end{aligned} \quad (40)$$

Hence we derive that $L_\alpha(Tf_n - Tf_0) \rightarrow 0$ and then $Tf_n \rightarrow Tf_0$. This means that T is a compact operator. $\square$

By the similar argument, one can conclude the following results for the scalar-valued little Lipschitz function spaces.

Theorem 12. Let $\alpha \in (0, 1)$. Suppose that $T : Lip_\alpha^b(X) \rightarrow Lip_\alpha^b(Y)$ is a nonzero weighted composition operator of the form (29).

- (1) If T is compact, then, for any $y_0 \in Y \setminus Y_0$, there is an open neighborhood U_0 of y_0 such that φ is supercontractive on U_0 and $\varphi(U_0)$ is totally bounded.
- (2) If φ is supercontractive on $Y \setminus Y_0$ and $\varphi(Y \setminus Y_0)$ is totally bounded, then T is compact.

Also here, the result of [19] also refers to the case where T is a composition operator.

Corollary 13. Suppose that X, Y are compact metric spaces, and T is a weighted composition operator of the form (29) between the following function spaces:

- (i) $0 < \alpha \leq 1$ and $T : Lip_\alpha^b(X) \rightarrow Lip_\alpha^b(Y)$;
- (ii) $0 < \alpha < 1$ and $T : Lip_\alpha^b(X) \rightarrow Lip_\alpha^b(Y)$.

Then T is compact if and only if φ is supercontractive on $Y \setminus Y_0$.

When T is a composition operator, that is, $h = T1 = 1$ in the form (29), then $Y_0 = \emptyset$ and we can establish the following results in [20, Theorem 1.1].

Corollary 14. Suppose that X, Y are metric spaces and $T : Lip_\alpha^b(X) \rightarrow Lip_\alpha^b(Y)$ is a composition operator; then T is compact if and only if φ is supercontractive and $\varphi(Y)$ is totally bounded.

In the following part of this section we have $X = Y$. Define $\varphi_0(x) = x$ and $\varphi_n(x) = \varphi(\varphi_{n-1}(x))$ for all $x \in X$ by induction. A point $x_0 \in X$ is said to be the fixed point of φ of order n , $n \in \mathbb{N}$, if $\varphi_n(x_0) = x_0$ and $\varphi_i(x_0) \neq x_0$ for any $i = 0, 1, \dots, n-1$.

Theorem 15. Let X be a complete metric space and $T : Lip^b(X) \rightarrow Lip^b(X)$ a weighted composition operator of form (29) satisfying: φ is supercontractive on $X \setminus X_0$ and $\varphi(X \setminus X_0)$ is totally bounded. Then we can derive that $\sigma(T) = \{0\} \cup \mathcal{S}$, where

$$\begin{aligned} \mathcal{S} &= \{\lambda : \lambda^n = h(x_0)h(\varphi(x_0)) \cdots h(\varphi_{n-1}(x_0)), \\ &\quad x_0 \text{ is a fixed point of } \varphi \text{ of order } n\}. \end{aligned} \quad (41)$$

Proof. Suppose that x_0 is a fixed point of φ of order n . If $h(\varphi_k(x_0)) = 0$ for some k , we can see that T is not surjective and hence $0 \in \sigma(T)$.

Assume that $h(\varphi_k(x_0)) \neq 0$ for any $k = 0, 1, 2, \dots, n-1$ and $\lambda^n = h(x_0) \cdots h(\varphi_{n-1}(x_0))$.

When $n = 1$, we have that $\lambda = h(x_0)$ and $\varphi(x_0) = x_0$. There exists $g \in Lip^b(X)$ such that $g(x_0) = 1$. There is no $f \in Lip^b(X)$ such that $(\lambda - T)f = g$. Indeed, if such f exists, we can derive that

$$\begin{aligned} 0 &= \lambda f(x_0) - h(x_0)f(x_0) = \lambda f(x_0) - h(x_0)f(\varphi(x_0)) \\ &= g(x_0) = 1, \end{aligned} \quad (42)$$

and this is impossible. This means that $\lambda \in \sigma(T)$.

When $n \geq 2$, let $\delta := \min\{d(\varphi_i(x_0), \varphi_j(x_0)) : 0 \leq i \neq j \leq n-1\}$, and define

$$\begin{aligned} g &= \frac{1}{n} \sum_{i=0}^{n-1} \frac{1}{\lambda^{n-i-1} h(x_0) \cdots h(\varphi_{i-1}(x_0))} \\ &\quad \times \max \left\{ 0, 1 - \frac{d(x, \varphi_i(x_0))}{\delta} \right\}. \end{aligned} \quad (43)$$

Here $h(\varphi_{-1}(x_0)) := 1$. Then, similar to the argument of [3, Proposition 3], we can derive that $\lambda \in \sigma(T)$.

On the other hand, for each $f \in Lip^b(X)$ with $\lambda f = Tf$, for some $\lambda \notin \{0\} \cup \mathcal{S}$, we will prove that $f = 0$. This implies that $\lambda \notin \sigma(T)$ and completes the proof.

From the assumption $\lambda f = Tf = h \cdot f \circ \varphi$, for all $x \in X$ and $n \in \mathbb{N}$, we derive that

$$\lambda^n f(x) = h(x)h(\varphi(x)) \cdots h(\varphi_{n-1}(x))f(\varphi_n(x)). \quad (44)$$

Given any $z \in X$, let $\mathcal{F} = \{\varphi_n(z) : n \in \mathbb{N} \cup \{0\}\}$ and $\mathcal{N} = \{n \in \mathbb{N} : |h(\varphi_n(z))| \geq \delta_0\}$; here δ_0 is any fixed number with $0 < \delta_0 < |\lambda|$. We provide that $f(z) = 0$, which implies that $f = 0$, by dividing into the following cases.

Case I ($\mathcal{F} \cap X_0 \neq \emptyset$). If there exists i_0 such that $h(\varphi_{i_0}(z)) = 0$, by (44) we can see that

$$\lambda^{i_0+1} f(z) = h(z)h(\varphi(z)) \cdots h(\varphi_{i_0}(z))f(\varphi_{i_0+1}(z)) = 0. \quad (45)$$

This implies that $f(z) = 0$.

Case II ($\mathcal{F} \subset X \setminus X_0$ and $\mathcal{F}$ is finite). Let $\mathcal{F} = \{z, \varphi(z), \dots, \varphi_{n_0}(z)\}$. Then there exists $0 \leq k \leq n_0$ such that $\varphi_{n_0+1}(z) = \varphi_k(z)$. This means that $\varphi_k(z)$ is a fixed point of φ of order $n_0 - k + 1$. By (44), we have that

$$\begin{aligned} \lambda^{n_0-k+1} f(\varphi_k(z)) \\ = h(\varphi_k(z))h(\varphi_{k+1}(z)) \cdots h(\varphi_{n_0}(z))f(\varphi_{n_0+1}(z)), \end{aligned} \quad (46)$$

and $f(\varphi_k(z)) = 0$ since $\lambda \notin \{0\} \cup \mathcal{S}$. Once again, by (44), we derive that

$$\lambda^k f(z) = h(z)h(\varphi(z)) \cdots h(\varphi_{k-1}(z))f(\varphi_k(z)) = 0, \quad (47)$$

and $f(z) = 0$.

Case III ($\mathcal{F} \subset X \setminus X_0$, $\mathcal{F}$ is infinite and $\mathcal{N}$ is infinite). Notice that $\{\varphi_n(z) : n \in \mathcal{N}\} \subset (X \setminus X_0) \cap \varphi(X \setminus X_0)$. Since $\varphi(X \setminus X_0)$ is totally bounded, we can derive that $\{\varphi_n(z) : n \in \mathcal{N}\}$ converges to a point $\bar{x} \in X$. Moreover, $\varphi_n(z) \rightarrow \bar{x}$ since φ is supercontractive. Then we have that $|h(\bar{x})| \geq \delta_0$ and $\varphi(\bar{x}) = \bar{x}$. By (44) we can see that $f(\bar{x}) = 0$. Since φ is supercontractive, there exists $\delta_1 > 0$ such that

$$d(\varphi(z_1), \varphi(z_2)) < \frac{|\lambda|}{2\|h\|_\infty} d(z_1, z_2) \quad (48)$$

when $0 < d(z_1, z_2) < \delta_1$.

Choose $N \in \mathbb{N}$ such that $d(\varphi_n(z), \bar{x}) < \delta_1$ for all $n \geq N$, and we have, for any $n \in \mathbb{N}$, that

$$\begin{aligned} |\lambda^n f(\varphi_N(z))| &= |h(\varphi_N(z)) h(\varphi_{N+1}(z)) \cdots \\ &\quad h(\varphi_{N+n-1}(z)) f(\varphi_{N+n}(z))| \\ &\leq \|h\|_\infty^n |f(\varphi_{N+n}(z))| \\ &= \|h\|_\infty^n |f(\varphi_{N+n}(z)) - f(\bar{x})| \\ &\leq \|h\|_\infty^n L(f) d(\varphi_{N+n}(z), \bar{x}) \\ &\leq \|h\|_\infty^n L(f) \frac{|\lambda|}{2\|h\|_\infty} d(\varphi_{N+n-1}(z), \bar{x}) \\ &\leq \cdots \leq \|h\|_\infty^n L(f) \left(\frac{|\lambda|}{2\|h\|_\infty} \right)^n d(\varphi_N(z), \bar{x}) \\ &= L(f) \left(\frac{|\lambda|}{2} \right)^n d(\varphi_N(z), \bar{x}). \end{aligned} \quad (49)$$

That is,

$$|f(\varphi_N(z))| \leq \frac{1}{2^n} L(f) d(\varphi_N(z), \bar{x}). \quad (50)$$

Since n is arbitrary, we can derive that $f(\varphi_N(z)) = 0$, and then $f(z) = 0$ since (44).

Case IV ($\mathcal{F} \subset X \setminus X_0$, $\mathcal{F}$ is infinite and $\mathcal{N}$ is finite). We can choose $N_0 \in \mathbb{N}$ such that $|h(\varphi_n(z))| < \delta_0$ for $n > N_0$. From (44), we have that

$$\begin{aligned} \lambda^n f(z) &= h(z) h(\varphi(z)) \cdots h(\varphi_{n-1}(z)) f(\varphi_n(z)), \end{aligned} \quad (51)$$

and then

$$|f(z)| \leq \|h\|_\infty^{N_0} \delta_0^{-N_0} \left(\frac{\delta_0}{\lambda} \right)^n \|f\|_\infty, \quad (52)$$

for all $n > N_0$. This implies that $f(z) = 0$ as $\delta_0 < |\lambda|$. $\square$
