We establish some new existence theorems on the positive solutions for nonlinear integro-differential equations which do not possess any monotone properties in ordered Banach spaces by means of Banach contraction mapping principle and cone theory based on some new comparison results.

1. Introduction

In this paper, we consider the existence of the unique positive solution and at least one positive solution for the following initial value problem (IVP) of the nonlinear integro-differential equation of mixed type in ordered Banach spaces E :

$$\begin{aligned} u''(t) &= g(t, u(t), (Tu)(t), (Su)(t)), \quad \forall t \in I, \\ u(0) &= u_0, \quad u'(0) = u_1, \end{aligned} \quad (1)$$

where $I = [0, a]$ ($a > 0$), $g(t, u(t), (Tu)(t), (Su)(t)) = f(t, u(t), u(t), (Tu)(t), (Su)(t))$, $u_0, u_1 \in E$, $f \in C[I \times P \times P \times P \times P, P]$, and f is nonincreasing with the second variable $u(t)$, with f is nondecreasing with the third variable $u(t)$. P is a positive cone in ordered Banach spaces E , and

$$\begin{aligned} (Tu)(t) &= \int_0^t k(t, s) u(s) ds, \\ (Su)(t) &= \int_0^a h(t, s) u(s) ds, \quad t \in I. \end{aligned} \quad (2)$$

In (2), $k \in C[D, R^+]$ and $h \in C[D_0, R^+]$, where $D = \{(t, s) \in R \times R : 0 \leq s \leq t \leq a\}$, $D_0 = \{(t, s) \in R \times R : (t, s) \in I \times I\}$, R^+ denotes the set of nonnegative real numbers, and R denotes the set of real numbers. In the special case when f does not

contain the third argument, Guo [1] proved the minimal and maximal solution of the following initial value problem:

$$u' = f(t, u, Tu), \quad t \in I, \quad u(t_0) = x_0, \quad (3)$$

under some stronger conditions. He used the topological degree theory and the monotone iterative technique. When f does not possess any monotone assumption, the problem of proving the existence results is an interesting and important question. The aim of the paper is to study this kind of problem. By means of Banach contraction mapping principle and cone theory based on some new comparison results, we obtain some new existence theorems of the solutions for the initial value problems of the nonlinear integro-differential equations of mixed type which does not possess any monotone properties in ordered Banach spaces. The new results obtained are quite general and are used to generalize, improve, and unify many recent results of [2–8]. Their results assert the existence of one solution, the minimal and maximal solution using monotone iterative technique with the stronger conditions. Our method is different from the method of mixed monotony, and the results obtained in the paper are new even if the space E is finite dimensional.

Inspired and motivated greatly by the above work, the aim of the paper is to consider the existence of positive solutions for the boundary value problem (1) under simpler conditions. The main results of problem (1) are obtained by making use

of new fixed point theorem. More specifically, in the proof of these theorems, we establish new comparison theorem and construct a special cone for strict set contraction operator. Our main results in essence improve and generalize the corresponding results of [1, 9–12]. Moreover, our method is different from those in [5, 10, 13].

The rest of the paper is organized as follows. In Section 2, we present some known results and introduce conditions to be used in the next section. The main theorems are formulated and proved in Section 3.

2. Preliminaries and Lemmas

In this section, we will state some necessary definitions and preliminary results.

Definition 1. Let E be a real Banach space. A nonempty closed set $P \subset E$ is called a cone if it satisfies the following two conditions:

- (1) $z \in P, \lambda > 0$ implies $\lambda z \in P$;
- (2) $z \in P, -z \in P$ implies $z = \theta$, where θ denotes the zero element of E .

A cone is said to be solid if it contains interior points, $\dot{P} \neq \emptyset$. The positive cone P is said to be generating if $E = P - P$; that is, every element $y \in E$ can be represented in the form $y = x - z$, where $x, z \in P$. Every cone with nonempty interior is generating. A cone P induces a partial ordering in E given by $u \leq v$ if $v - u \in P$. If $u \leq v$ and $u \neq v$, we write $u < v$; if cone P is solid and $v - u \in \dot{P}$, we write $u \ll v$.

Definition 2. A cone $P \subset E$ is said to be normal if there exists a positive constant v such that $\|x + y\| \geq v, \forall x, y \in P, \|x\| = 1, \|y\| = 1$.

Proposition 3. A positive cone P is called normal if and only if there exists $N > 0$ such that $0 \leq x \leq y$ implies $\|x\| \leq N\|y\|$. The norm on E is called monotone if $0 \leq u \leq v$ implies $\|u\| \leq \|v\|$. The cone P is said to be normal if and only if there exists an equivalent monotone norm on E .

For further details on cone theory, one can refer to [2, 14].

Let $P = \{u \in C[I, E] : u(t) \geq \theta \text{ for } t \in I\}$, where $C[I, E]$ denotes the Banach space of all continuous mapping $u : I \rightarrow E$ with norm $\|u\| = \max\{u : t \in I\}$. It is easy to see that P is a cone in $C[I, E]$, and so it defines a partial order in $C[I, E]$ by $u \leq v$ if and only if $u(t) \leq v(t)$ for all $t \in I$. Given a cone P , the dual of P is defined as $P^* = \{\varphi \in E^* : \varphi(u) \geq 0 \text{ for } u \in P\}$, where E^* is the dual of E .

Let $k_0 = \max\{k(t, s) : (t, s) \in D\}$, $h_0 = \max\{h(t, s) : (t, s) \in D_0\}$. For any $H \subset C[I, E]$ and $t \in I$, let

$$\begin{aligned} H(t) &= \{u(t) : u \in H\}, \\ (TH)(t) &= \{(Tu)(t) : u \in H\}, \\ (SH)(t) &= \{(Su)(t) : u \in H\}. \end{aligned} \quad (4)$$

Definition 4. Let E be a metric space and S be a bounded subset of E . The measure of noncompactness $Y(S)$ of S is defined by

$$Y(S) = \inf \{\delta > 0 : S \text{ admits a finite cover by sets of diameter } \leq \delta\}. \quad (5)$$

Definition 5. An operator $B : D \rightarrow E$ is said to be completely continuous if it is continuous and compact. B is called a k -set-contraction ($k \geq 0$) if it is continuous, bounded, and $Y(B(S)) \leq kY(S)$ for any bounded set $S \subset D$, where $Y(S)$ denotes the measure of noncompactness of S .

A k -set-contraction is called a strict-set-contraction if $k < 1$. An operator B is said to be condensing if it is continuous, bounded, and $Y(B(S)) < Y(S)$ for any bounded set $S \subset D$ with $Y(S) > 0$.

Obviously, if B is a strict-set-contraction, then B is a condensing mapping, and if operator B is completely continuous, then B is a strict-set-contraction.

Definition 6 (see [15]). Let E be a Banach space, and let $A : E \times E \rightarrow E$. The mapping A is said to have the mixed monotone property if $A(x, y)$ is monotone nonincreasing in u and is monotone nondecreasing in v ; that is,

$$\begin{aligned} \text{for any } u_1, u_2 \in E, \quad u_1 \leq u_2 &\implies A(u_1, v) \geq A(u_2, v), \\ \text{for any } v_1, v_2 \in E, \quad v_1 \leq u_2 &\implies A(u, v_1) \leq A(u, v_2). \end{aligned} \quad (6)$$

Definition 7 (see [15]). A couple point $(x, y) \in E \times E$ is said to be a coupled fixed point of the mapping $A : E \times E \rightarrow E$ if $u = A(u, v)$ and $v = A(v, u)$.

Lemma 8 (see [2, 14]). A positive cone P is normal and generating if and only if there exists a positive constant $\tau > 0$ and $y, z \in P$ such that $x = y - z$ for all $x \in P$ and $\|y\| \leq \tau\|x\|, \|z\| \leq \tau\|x\|$.

The following lemma plays a key role for improving the main results.

Lemma 9. Let P be a normal generate cone, and let $A : P \times P \rightarrow P$ be a nonlinear operator. If there exists a positive bounded linear operator $L : P \rightarrow P$ such that $r(L) < 1$ and

$$\begin{aligned} -L(x - \bar{x} + \bar{y} - y) &\leq A(x, y) - A(\bar{x}, \bar{y}) \\ &\leq L(x - \bar{x} + \bar{y} - y), \\ \forall x, \bar{x}, y, \bar{y} \in P, \quad x &\geq \bar{x}, \quad y \leq \bar{y}, \end{aligned} \quad (7)$$

then A has a unique positive fixed point x^* , and for any $x_0 \in P$, let $x_n = A(x_{n-1}, x_{n-1})$ ($n = 1, 2, \dots$), $x_n \rightarrow x^*$ ($n \rightarrow \infty$).

Proof. Since $r(L) < 1$, then $r(L) = \lim_{n \rightarrow \infty} \|L^n\|^{1/n} < 1$. Thus, there exists a natural number n_0 and $0 < \alpha < 1$ such that

$$\|L^{n_0}\| \leq \alpha^{n_0}. \quad (8)$$

Since P is generate, it follows from Lemma 8 that there exist $\tau > 0$, $y, z \in P$ such that $x = y - z$ and

$$\|y\| \leq \tau \|x\|, \quad \|z\| \leq \tau \|x\|, \quad \forall x \in P. \quad (9)$$

Then $\|y+z\| \leq 2\tau \|x\|$, $\forall x \in P$. Suppose that $x, y, z \in P$ are not in the same line for any $0 \leq x - y \leq z$. Let $u_1 = (1/2)(x + y - z)$, $u_2 = x - y + z$, $u_3 = -x + y + z$. Then $u_1, u_2, u_3 \in P$ and $x \geq y \geq u_1$, $x - u_1 = (1/2)u_2$, $y - u_1 = (1/2)u_3$, $u_2 + u_3 = 2z$. It follows from (7) that

$$-\frac{L}{2}u_2 \leq A(x, x) - A(u_1, x) \leq \frac{L}{2}u_2, \quad (10)$$

$$\begin{aligned} -\frac{L}{2}(u_2 + u_3) &\leq A(u_1, x) - A(y, u_1) \\ &\leq \frac{L}{2}(u_2 + u_3), \end{aligned} \quad (11)$$

$$-\frac{L}{2}u_3 \leq A(y, u_1) - A(y, y) \leq \frac{L}{2}u_3. \quad (12)$$

By virtue of (10) + (12) - (11), we have

$$\begin{aligned} -\frac{L}{2}(u_2 + u_3) &\leq A(x, x) - A(y, y) \leq \frac{L}{2}(u_2 + u_3), \\ -L \cdot 2z &\leq A(x, x) - A(y, y) \leq L \cdot 2z. \end{aligned} \quad (13)$$

We first define the operator $\tilde{A} : P \rightarrow P$ as the following $\tilde{A}x = A(x, x)$, $x \in P$. Let $w = 2z$. Then $-Lw \leq \tilde{A}x - \tilde{A}y \leq Lw$. Since L is a positive bounded linear operator, then $Lw \in P$. By induction, it is easy to see that

$$-L^n w \leq \tilde{A}^n x - \tilde{A}^n y \leq L^n w, \quad L^n w \in P. \quad (14)$$

Since $w \in P$ is arbitrary and n_0 is taken as in (8), we get

$$\|\tilde{A}^{n_0} x - \tilde{A}^{n_0} y\| \leq L^{n_0} \|x - y\| \leq \alpha^{n_0} \|x - y\|. \quad (15)$$

From $0 < \alpha < 1$ and Banach contract principle, we know that $\tilde{A}^{n_0}$ has the unique positive fixed point x^* in P ; that is, x^* is the unique positive solution of operator equation $x = A(x, x)$. And for any $x_0 \in E$, let $x_n = A(x_{n-1}, x_{n-1})$ ($n = 1, 2, \dots$), we have $\|x_n - x^*\| \rightarrow 0$ ($n \rightarrow \infty$). $\square$

Remark 10. The results of Lemma 9 obtained are quite general and are used to improve, generalize, and unify many results of Chen [13], Guo [9], Krasnosel'skii and Zabreiko [16], Zhang [11], Su et al. [10], and Liu [12]. Not only do we obtain the existence and uniqueness of fixed points for mixed nonmonotone binary operators in ordered Banach spaces, but we also solve the difficult open problem that nonmonotone binary operator has unique fixed points under some weaker conditions.

Lemma 11 (see [17]). *Let E be a Banach space and $H \subset C[I, E]$ if H is a countable set of strongly measurable functions $y : I \rightarrow E$ such that there exists $\varphi \in L[I, R^+]$ such that $\|y(t)\| \leq \varphi(t)$, $t \in I$, $y \in H$. Then $\Upsilon(H(t))$ is Lebesgue integrable on I , and*

$$\Upsilon\left(\left\{\int_I y(s) ds : y \in H\right\}\right) \leq 2 \int_I \Upsilon(H(s)) ds. \quad (16)$$

Lemma 12 (see [1, 18]). *Let $H \subset C[J, E]$ be bounded and equicontinuous; then $\Upsilon(H(t))$ is continuous on I , and*

$$\Upsilon\left(\int_I H(s) ds\right) \leq \int_I \Upsilon(H(s)) ds. \quad (17)$$

Lemma 13 (see [2, 19]). *Let X be a Banach space, $K \subset X$ closed and convex, and $F : K \rightarrow K$ continuous with the further property that for some $x \in K$ we have $B \subset K$ countable. $\bar{B} = \overline{\text{co}}(\{x\} \cap F(B))$ implies that B is relatively compact. Then F has a fixed point in K .*

Lemma 14. *Assume that $m \in C[I, R^+]$ satisfies*

$$m(t) \leq M \int_{t_0}^t m(s) ds + M^* \int_{t_0}^{t+a} m(s) ds, \quad t \in I, \quad (18)$$

where $M > 0$ and $M^* \geq 0$ are constants. Then $m(t) \equiv 0$ for $t \in I$ provided one of the following two conditions hold:

- (i) $M > M^*(e^{M(t-t_0)} - 1)$;
- (ii) $a(M + M^*) < 1$.

Proof. Suppose that (i) holds. Let $p(t) = \int_{t_0}^t m(s) ds$; then $p(t_0) = 0$, $p'(t) = m(t) \geq 0$, for $t \in I$. From (18), we know that

$$p'(t) \leq Mp(t) + M^* p(t_0 + a), \quad t \in I. \quad (19)$$

Since $e^{-M(t-t_0)} > 0$, we have

$$(p(t) e^{-M(t-t_0)})' \leq M^* p(t_0 + a) e^{-M(t-t_0)}, \quad t \in I. \quad (20)$$

Integrate from t_0 to t ; noticing $p(t_0) = 0$, we have

$$\begin{aligned} 0 \leq p(t) e^{-M(t-t_0)} &\leq \int_{t_0}^t M^* p(t_0 + a) e^{-M(s-t_0)} ds \\ &= \frac{M^*}{M} p(t_0 + a) (1 - e^{M(t-t_0)}), \quad t \in I. \end{aligned} \quad (21)$$

Hence,

$$0 \leq p(t) \leq \frac{M^*}{M} p(t_0 + a) (e^{M(t-t_0)} - 1), \quad t \in I. \quad (22)$$

We claim that

$$p(t_0 + a) = 0. \quad (23)$$

Otherwise, $p(t_0 + a) > 0$; then we take $t = t_0 + a$ in (22), we obtain $M \leq M^*(e^{M(t-t_0)} - 1)$, which contradicts assumption (i).

Therefore, from (22) and (23), we know that $p(t) = \int_{t_0}^t m(s) ds = 0$. Consequently, $m(s) \equiv 0$ a.e. on $t \in I$.

Let us suppose now that (ii) holds. Then

$$m(t) \leq (M + M^*) \int_{t_0}^{t_0+a} m(s) ds, \quad t \in I. \quad (24)$$

It follows by integrating the above inequality that

$$\int_{t_0}^{t_0+a} m(s) ds \leq a(M + M^*) \int_{t_0}^{t_0+a} m(s) ds, \quad (25)$$

which, by assumption (ii), implies that $\int_{t_0}^{t_0+a} m(s) ds = 0$ and so $m(t) \equiv 0$ a.e. on I . The proof of Lemma 14 is therefore complete. $\square$

Lemma 15 (see [2, 19]). *$H \subset C^1[I, E]$ is relatively compact if and only if each element $y(t) \in H$ and $y'(t) \in H$ are uniformly bounded and equicontinuous on I .*

3. Main Results

We are now in a position to prove our main results concerning the unique positive solution and at least one positive solution.

Theorem 16. *Suppose that P is a normal solid cone whenever $t \in I$; there exists $\bar{M} > 0$, $y_1, \bar{y}_1, y_2, \bar{y}_2 \in P$, $y_1 \geq \bar{y}_1$, $y_2 \leq \bar{y}_2$ such that*

$$\begin{aligned} & f(t, y_1, y_2, Ty_1, Sy_1) - f(t, \bar{y}_1, \bar{y}_2, T\bar{y}_1, S\bar{y}_1) \\ & \geq -\bar{M} [y_1 - \bar{y}_1 + \bar{y}_2 - y_2 + Ty_1 - T\bar{y}_1], \end{aligned} \quad (26)$$

$$\begin{aligned} & f(t, y_1, y_2, Ty_1, Sy_1) - f(t, \bar{y}_1, \bar{y}_2, T\bar{y}_1, S\bar{y}_1) \\ & \leq \bar{M} [y_1 - \bar{y}_1 + \bar{y}_2 - y_2 + Ty_1 - T\bar{y}_1]. \end{aligned} \quad (27)$$

Then IVP (1) has the unique positive solution x^* in $C^2[I, P]$.

Proof. Define operator $A : C[I, P] \times C[I, P] \rightarrow C[I, P]$ as the following:

$$\begin{aligned} A(u, v) &= u_0 + tu_1 \\ &+ \int_0^t (t-s) f(s, u(s), v(s), \\ &\quad (Tu)(s), (Su)(s)) ds, \quad t \in I. \end{aligned} \quad (28)$$

Then $u \in C^2[I, P]$ is a solution of IVP (1) if and only if $u \in C[I, P]$ is a fixed point of A ; that is, $u = A(u, u)$ for any $u, v, \bar{u}, \bar{v} \in C[I, P]$, $u \geq \bar{u}$, $v \leq \bar{v}$. From (26) and (28), we know that

$$\begin{aligned} & A(u, v) - A(\bar{u}, \bar{v}) \\ & \geq -\bar{M}a \int_0^t [(u - \bar{u}) + (\bar{v} - v) + T(u - \bar{u})] ds \\ & \geq -\bar{M}a \left[(1+a) \int_0^t (u - \bar{u}) ds + \int_0^t (\bar{v} - v) ds \right] \\ & \geq -\bar{M}a(1+a) \int_0^t (u - \bar{u} + \bar{v} - v) ds, \end{aligned} \quad (29)$$

$$A(u, v) - A(\bar{u}, \bar{v})$$

$$\begin{aligned} & \leq \bar{M}a \int_0^t [(u - \bar{u}) + (\bar{v} - v) + T(u - \bar{u})] ds \\ & \leq \bar{M}a \left[(1+a) \int_0^t (u - \bar{u}) ds + \int_0^t (\bar{v} - v) ds \right] \\ & \leq \bar{M}a(1+a) \int_0^t (u - \bar{u} + \bar{v} - v) ds. \end{aligned} \quad (30)$$

From (29) and (30), for any $u, v, \bar{u}, \bar{v} \in C[I, P]$, $u \geq \bar{u}$, $v \leq \bar{v}$ we know that

$$-L(u - \bar{u} + \bar{v} - v) \leq A(u, v) - A(\bar{u}, \bar{v}) \leq L(u - \bar{u} + \bar{v} - v), \quad (31)$$

where

$$(Lw)(t) = \bar{M}a(1+a) \int_0^t w(s) ds. \quad (32)$$

Now we prove that $r(L) < 1$, for $t \in I$. From (32), we know that

$$\|(Lu)(t)\| = \bar{M}a(1+a)t\|u\|. \quad (33)$$

Denote $\eta = \bar{M}a(1+a)$. From (32) and (33), we get

$$\begin{aligned} \|(L^2u)(t)\| &\leq \eta \int_0^t (Lu)(s) ds \\ &\leq \eta\|u\| \int_0^t s ds = \frac{\eta^2 t^2}{2!} \|u\|, \quad \forall t \in I. \end{aligned} \quad (34)$$

By induction, for any natural number n , we have

$$\begin{aligned} \|(L^n u)(t)\| &\leq \frac{\eta^n t^n}{n!} \|u\|, \quad \forall t \in I, \\ \|L^n u\| &= \max_{t \in I} \|(L^n u)(t)\| \leq \frac{\eta^n t^n}{n!} \|u\|. \end{aligned} \quad (35)$$

Therefore, $r(L) = \lim_{n \rightarrow \infty} \|L^n\|^{1/n} = 0 < 1$.

Since P is normal solid cone in $C[I, E]$ and P is generate, by virtue of Lemma 9, we know that A has a unique positive fixed point x^* in P ; that is, IVP (1) has a unique positive solution x^* in $C^2[I, P] \subset C^2[I, E]$. $\square$

Remark 17. The conditions of Theorem 16 cannot be obtained by Chen and Zhuang [3], Lakshmikantham et al. [8], and Sun and Liu [20]. We obtain a unique positive solution of IVP (1). The conditions imposed on nonlinear term f are sharper, and the result is new.

Denote $M'(R) = \sup\{\|f(t, u, v, w, z)\| : (t, u, v, w, z) \in I \times B_R \times B_R \times B_R \times B_R\}$, $B_R = \{x \in P : \|x\| \leq R\}$.

Theorem 18. *Assume that $f : I \times P \times P \times P \times P \rightarrow P$ satisfying the following conditions.*

(H₁) *For any $R > 0$, f is uniformly continuous on $I \times B_R \times B_R \times B_R \times B_R$ and*

$$\lim_{R \rightarrow \infty} \frac{M'(R)}{R} < (aa_0)^{-1}, \quad \text{where } a_0 = \max\{1, ak_0, ah_0\}. \quad (36)$$

(H₂) There exists $L > 0$ such that

$$\begin{aligned} &Y(f(t, B(t), B(t), (TB)(t), (SB)(t))) \\ &\leq \lambda_1 Y(B(t)) + \lambda_2 Y((TB)(t)) + \lambda_3 Y((SB)(t)) \end{aligned} \quad (37)$$

for any bounded set $S \subset C[I, P] \subset C[I, E]$, $t \in I$, and $2(\lambda_1 + \lambda_2 ak_0) > 0$, $2\lambda_3 h_0 a \geq 0$ with $2a(\lambda_1 + \lambda_2 ak_0 + \lambda_3 ah_0) < 1$.

Then IVP (1) has at least one positive solution in $C^2[I, P] \subset C^2[I, E]$.

Proof. We first define the operator $F : C[I, P] \rightarrow C[I, P]$ by the formula

$$\begin{aligned} (Fu)(t) &= u_0 + tu_1 \\ &+ \int_0^t (t-s) f(s, u(s), u(s), (Tu)(s), (Su)(s)) ds, \\ &t \in I. \end{aligned} \quad (38)$$

It is easy to know that u is a solution of IVP (1) if and only if u is a fixed point of F .

It follows from (H₁) that there exist $0 < r < (aa_0)^{-1}$ and $R_1 > 0$ such that

$$\frac{M'(R)}{R} < r, \quad \text{for } R \geq a_0 R_1. \quad (39)$$

Let

$$\begin{aligned} R^* &= \max \{R_1, (\|u_0\| + a\|u_1\|)(1 - aa_0 r)^{-1}\}, \\ B_I(R^*) &= \{u \in C[I, P] : \|u\| \leq R^*\}. \end{aligned} \quad (40)$$

Then for any $u \in B_I(R^*)$, we have

$$\begin{aligned} \|u\| &= R^* \leq a_0 R^*, \quad \|Tu\| \leq ak_0 \|u\| \leq ak_0 R^* \leq a_0 R^*, \\ \|Su\| &\leq ah_0 \|u\| \leq ah_0 R^* \leq a_0 R^*. \end{aligned} \quad (41)$$

It follows from (38) and (39) that

$$\begin{aligned} \|Fu\| &\leq \|u_0\| + a\|u_1\| + aM'(a_0 R^*) \\ &\leq \|u_0\| + a\|u_1\| + aa_0 R^* r \leq R^*. \end{aligned} \quad (42)$$

Set $K = \overline{\text{co}}(B_I(R^*))$. Then F is a continuous operator from K into K . It is easy to see from (38), (H₁), and the normality of P that $K \subset B_I(R^*)$ is uniformly bounded and equicontinuous on I .

Let $B \subset K \subset C[I, P]$ be any countable subset satisfying $\overline{B} = \overline{\text{co}}(\{u(t)\} \cap (FB)(t))$ for any $t \in I$. By applying Lemma 12, we get

$$\begin{aligned} Y(B(t)) &= \overline{Y(B(t))} = Y((FB)(t)) \\ &\leq 2 \int_0^t [\lambda_1 Y(B(s)) + \lambda_2 Y((TB)(s)) \\ &\quad + \lambda_3 Y((SB)(s))] ds \end{aligned}$$

$$\begin{aligned} &\leq 2 \int_0^t \left[\lambda_1 Y(B(s)) + \lambda_2 k_0 \int_0^s Y(B(\tau)) d\tau \right. \\ &\quad \left. + \lambda_3 h_0 \int_0^{t_0+a} Y(B(\tau)) d\tau \right] ds \\ &= 2\lambda_1 \int_0^t Y(B(s)) ds \\ &\quad + 2\lambda_2 k_0 \int_0^t (t-s) Y(B(s)) ds \\ &\quad + 2\lambda_3 h_0 t \int_0^{t_0+a} Y(B(s)) ds \\ &\leq (2\lambda_1 + 2\lambda_2 ak_0) \\ &\quad \times \int_0^t Y(B(s)) ds + 2\lambda_3 ah_0 \int_0^{t_0+a} Y(B(s)) ds \\ &= M \int_0^t Y(B(s)) ds \\ &\quad + M^* \int_0^{t_0+a} Y(B(s)) ds = 0, \end{aligned} \quad (43)$$

where $M = (2\lambda_1 + 2\lambda_2 ak_0)$, $M^* = 2\lambda_3 ah_0$. Thus, by Ascoli-Arzelà theorem, B is relative compact in $X = C[I, E]$. It follows from Lemma 14 that F has a fixed point $x^* \in K = \overline{\text{co}}(F(B_I(R^*)))$ which is a solution of IVP (1). This completes the proof of Theorem 18. $\square$

Remark 19. The conditions imposed on nonlinear term do not possess any monotone properties. The results of the paper cannot be obtained by making use of the fixed point theorems on decreasing and increasing operators or mixed monotone operators.

Conflict of Interests

The author declares no conflict of interests.

Acknowledgments

The author is very grateful to Professor Lishan Liu, Professor Tijing Xiao, and Professor R. P. Agarwal for their many valuable comments. The work is supported financially by the Foundation of Shanghai Natural Science (13ZR1430100) and the Foundation of Shanghai Municipal Education Commission (DYL201105).
