We consider an initial-boundary value problem for general higher-order hyperbolic equation in an infinite cylinder with the base containing conical points on the boundary. We establish several results on the unique solvability, the regularity, and the asymptotic behaviour of the solution near the conical points.

1. Introduction

A large number of investigations have been devoted to boundary value problems in nonsmooth domains with conical points. Up to now, elliptic boundary value problems in domains with point singularities have been thoroughly investigated (see, e.g., [1–3]).

We are concerned with hyperbolic equations in domains with conical points. This topic has been investigated in many works with different approaches. For example, [4, 5] the Cauchy-Dirichlet and Cauchy-Neumann problems for second-order hyperbolic systems with the coefficients independent of the time variable were treated in which the asymptotics of the solutions were established with explicit formulas for the coefficients. In [6–9], initial-boundary value problems for general higher-order hyperbolic equations and systems with the coefficients depending on both spatial and time variable in a domain containing conical points were studied in which the unique solvability, the regularity, and the asymptotic behaviour of the solutions near the conical points were obtained. In the present paper, these results are extended to initial-boundary value problems for general higher-order hyperbolic equations with more general boundary conditions in infinite cylinders with the bases containing conical points. Such boundary conditions have been considered for elliptic equations in [10, 11] and for parabolic equations in [12, 13].

Our paper is organized as follows. Section 2 is devoted to some notations and the formulation of the problem. The

main results will be stated in Section 3. The proofs of the main theorems will be given in Sections 4 and 5.

2. Notations and the Formulation of the Problem

Let G be a bounded domain in $\mathbb{R}^n$ ($n \geq 2$) with the boundary ∂G . We suppose that $\Gamma = \partial G \setminus \{0\}$ is a smooth manifold and G in a neighborhood U of the origin 0 coincides with the cone $K = \{x : x/|x| \in \Omega\}$, where Ω is a smooth domain on the unit sphere S^{n-1} in $\mathbb{R}^n$. For each T , $0 < T \leq \infty$, denote $Q_T = G \times (0, T)$, $G_T = G \times \{T\}$. Specifically, we set $Q = Q_\infty = G \times \mathbb{R}_+^*$, $S = \Gamma \times \mathbb{R}_+$, where $\mathbb{R}_+^* = (0, \infty)$, $\mathbb{R}_+ = [0, \infty)$. For each multiindex $\alpha = (\alpha_1, \dots, \alpha_n) \in \mathbb{N}^n$, set $|\alpha| = \alpha_1 + \dots + \alpha_n$ and $\partial_x^\alpha = \partial_x^{\alpha_1} \dots \partial_x^{\alpha_n}$. For a nonnegative integer k we write u_t^k instead of $\partial_t^k u$.

We introduce the following differential operator:

$$Lu = L(x, t, \partial)u = \sum_{|\alpha|, |\beta| \leq m} (-1)^{|\alpha|} \partial^\alpha (a_{\alpha\beta} \partial^\beta u), \quad (1)$$

where $a_{\alpha\beta} = a_{\alpha\beta}(x, t)$ are bounded complex-valued functions defined in $\overline{Q}$. We assume that $a_{\alpha\beta} = (-1)^{|\alpha|+|\beta|} \overline{a_{\beta\alpha}}$ for all $|\alpha|, |\beta| \leq m$. This means the differential operator L is formally

self-adjoint. We assume further that there exists a positive constant μ_0 such that

$$\sum_{|\alpha|=|\beta|=m} a_{\alpha\beta}(x, t) \eta_\beta \overline{\eta_\alpha} \geq \mu_0 \sum_{|\alpha|=m} |\eta_\alpha|^2, \quad (2)$$

for all $\eta_\alpha \in \mathbb{C}$, $|\alpha| = m$ and all $(x, t) \in \overline{Q}$.

We introduce also a system of boundary operators:

$$B_j = B_j(x, t, \partial_x) = \sum_{|\alpha| \leq \mu_j} b_{j,\alpha}(x, t) \partial_x^\alpha, \quad j = 1, \dots, m, \quad (3)$$

on S with smooth coefficients in $\overline{Q}$. Suppose that

$$\begin{aligned} \text{ord} B_j &= \mu_j \leq m-1 \quad \text{for } j = 1, \dots, \chi, \\ m \leq \text{ord} B_j &= \mu_j \leq 2m-1 \quad \text{for } j = \chi+1, \dots, m, \end{aligned} \quad (4)$$

and the coefficients of B_j are independent of t if $\text{ord} B_j < m$, where $\text{ord} B_j$ stands for the order of the differential operator B_j . Suppose that $\{B_j(x, t, \partial_x)\}_{j=1}^m$ is a normal system on S for all $t \in \mathbb{R}_+$; that is, the two following conditions are satisfied:

- (i) $\mu_j \neq \mu_k$ for $j \neq k$,
- (ii) $B_j^\circ(x, t, \nu(x)) \neq 0$ for all $(x, t) \in S$, $j = 1, \dots, m$.

Here $\nu(x)$ is the unit outer normal to S at point x , and $B_j^\circ(x, t, \partial_x)$ is the principal part of $B_j(x, t, \partial_x)$,

$$B_j^\circ = B_j^\circ(x, t, \partial_x) = \sum_{|\alpha|=\mu_j} b_{j,\alpha}(x, t) \partial_x^\alpha, \quad j = 1, \dots, m. \quad (5)$$

Furthermore, we assume that $B_j^\circ(0, t, \nu(x)) \neq 0$ for all $x \in S$ sufficiently close to the origin 0.

To be able to reduce the problem considered to variational form we assume that there are boundary operators Φ_j on S , $j = 1, \dots, m$, such that

$$\begin{aligned} B(t, u, \nu) &= \int_G Lu \overline{\nu} dx + \sum_{j=1}^{\chi} \int_S \Phi_j u \overline{B_j \nu} ds \\ &\quad + \sum_{j=\chi+1}^m \int_S B_j u \overline{\Phi_j \nu} ds, \end{aligned} \quad (6)$$

for all $u, \nu \in C_0^\infty(\overline{G} \setminus \{0\})$ and a.e. $t \in \mathbb{R}_+$. Here

$$B(t, u, \nu) = \sum_{|\alpha|, |\beta|=0}^m \int_G a_{\alpha\beta}(\cdot, t) \partial_x^\beta u \overline{\partial_x^\alpha \nu} dx, \quad t \in \mathbb{R}_+, \quad (7)$$

is the bilinear form associated with the operator $L(x, t, \partial_x)$. Of course this is an essential restriction on the structure of the boundary operators in (3). However, if the system of boundary operators in (3) is a Dirichlet system (then all $\text{ord} B_j$ are less than m) or a generalized Neumann system (then $m \leq \text{ord} B_j \leq 2m-1$ for all $j = 1, \dots, m$), the equality (6) holds for a suitable system Φ_j , $j = 1, \dots, m$ (see [10, Section I.7]).

In this paper, we consider the following problem:

$$\begin{aligned} u_{tt} + Lu &= f \text{ in } Q, \\ B_j u &= 0 \text{ on } S, \quad j = 1, \dots, m, \end{aligned} \quad (8)$$

$$u|_{t=0} = u_t|_{t=0} = 0 \text{ in } G. \quad (9)$$

Before giving the definition of generalized solutions to this problem, let us introduce some needed functional spaces.

Let us denote by $H^l(G)$ ($l \in \mathbb{N}$) the usual Sobolev space of all functions u defined in G with the norm

$$\|u\|_{H^l(G)} = \left(\int_G \sum_{|\alpha| \leq l} |D^\alpha u|^2 dx \right)^{1/2} < \infty. \quad (10)$$

If $l \geq 1$, by $H^{l-(1/2)}(\Gamma)$ we denote the space of traces of functions in $H^l(G)$ on Γ with the norm

$$\|u\|_{H^{l-(1/2)}(\Gamma)} = \inf \{ \|v\|_{H^l(G)} : v \in H^l(G), v|_\Gamma = u \}. \quad (11)$$

We set

$$H_B^m(G) = \{ u \in H^m(G) : B_j u = 0 \text{ on } S \text{ for } j = 1, \dots, \chi \}, \quad (12)$$

with the same norm as in $H^m(G)$. By $V_{2,\alpha}^l(G)$ ($\alpha \in \mathbb{R}$) we denote the closure of $C_0^\infty(\overline{G} \setminus \{0\})$ with respect to the norm

$$\|u\|_{V_{2,\alpha}^l(G)} = \left(\sum_{|p| \leq l} \int_G r^{2(\alpha+|p|-l)} |D^p u|^2 dx \right)^{1/2}, \quad (13)$$

where $r = |x| = (\sum_{k=1}^n x_k^2)^{1/2}$. By $H_\alpha^l(G)$ we denote the weighted Sobolev space of functions u defined in G with the norm

$$\|u\|_{H_\alpha^l(G)} = \left(\sum_{|p| \leq l} \int_G r^{2\alpha} |D^p u|^2 dx \right)^{1/2} < +\infty. \quad (14)$$

If $l \geq 1$, then $V_\alpha^{l-1/2}(\Gamma)$, $H_\alpha^{l-1/2}(\Gamma)$ denote the spaces consisting of traces of functions from respective spaces $V_{2,\alpha}^l(G)$, $H_\alpha^l(G)$ on the boundary Γ with the respective norms

$$\|u\|_{V_\alpha^{l-1/2}(\Gamma)} = \inf \{ \|v\|_{V_{2,\alpha}^l(G)} : v \in V_{2,\alpha}^l(G), v|_\Gamma = u \}, \quad (15)$$

$$\|u\|_{H_\alpha^{l-1/2}(\Gamma)} = \inf \{ \|v\|_{H_\alpha^l(G)} : v \in H_\alpha^l(G), v|_\Gamma = u \}.$$

Let X, Y be Banach spaces, $0 < T \leq \infty$. We denote by $L_2((0, T), X)$ the space of all functions $u : (0, T) \rightarrow X$ such that

$$\|u\|_{L_2((0, T), X)} = \left(\int_0^T \|u(t)\|_X^2 dt \right)^{1/2} < \infty, \quad (16)$$

and by $H^1((0, T), X, Y)$ the space of all functions $u \in L_2((0, T), X)$ such that $u_t \in L_2((0, T), Y)$. The norm in $H^1((0, T), X, Y)$ is defined by

$$\|u\|_{H^1((0, T), X, Y)} = \left(\|u\|_{L_2((0, T), X)}^2 + \|u_t\|_{L_2((0, T), Y)}^2 \right)^{1/2}. \quad (17)$$

For some $\gamma \in \mathbb{R}$, we denote by $L_2(\mathbb{R}_+^*, X, \gamma)$ the space of all functions $u : \mathbb{R}_+^* \rightarrow X$ such that

$$\|u\|_{L_2(\mathbb{R}_+^*, X, \gamma)} = \left(\int_0^\infty \|u(t)\|_X^2 e^{-2\gamma t} dt \right)^{1/2} < \infty, \quad (18)$$

and by $H^1(\mathbb{R}_+^*, X, Y, \gamma)$ the space of all functions $u \in L_2(\mathbb{R}_+^*, X, \gamma)$ such that $u_t \in L_2(\mathbb{R}_+^*, Y, \gamma)$ with the norm

$$\|u\|_{H^1(\mathbb{R}_+^*, X, Y, \gamma)} = \left(\|u\|_{L_2(\mathbb{R}_+^*, X, \gamma)}^2 + \|u_t\|_{L_2(\mathbb{R}_+^*, Y, \gamma)}^2 \right)^{1/2}. \quad (19)$$

For shortness, we set

$$\begin{aligned} H_B^{m,1}(Q_T) &= H^1((0, T), H_B^m(G), L_2(G)), \\ L_2(Q, \gamma) &= L_2(\mathbb{R}_+^*, L_2(G), \gamma), \\ H^{l,0}(Q, \gamma) &= L_2(\mathbb{R}_+^*, H^l(G), \gamma), \\ H^{l,1}(Q, \gamma) &= H^1(\mathbb{R}_+^*, H^l(G), L_2(G), \gamma), \\ V_{2,\beta}^{l,0}(Q, \gamma) &= L_2(\mathbb{R}_+^*, V_{2,\beta}^l(G), \gamma), \\ H_\beta^{l,0}(Q, \gamma) &= L_2(\mathbb{R}_+^*, H_\beta^l(G), \gamma), \\ H_\beta^{l,1}(Q, \gamma) &= H^1(\mathbb{R}_+^*, H_\beta^l(G), L_2(G), \gamma). \end{aligned} \quad (20)$$

Now the definition of generalized solutions of the problem (8)-(9) is given as follows.

Definition 1. Let f be a given function defined on Q which belongs to $L_2(Q_T)$ for each $T > 0$. A function $u \in H_B^{m,1}(Q, \gamma)$ for some $\gamma \in \mathbb{R}$ is called a generalized solution of the problem (8)-(9) if and only if $u|_{t=0} = 0$, and for each $T > 0$ the equality

$$\begin{aligned} & - \int_0^T \int_G u_t \bar{\eta}_t dt + \sum_{|\alpha|, |\beta|=0}^m \int_0^T \int_G a_{\alpha\beta}(x, t) \partial_x^\beta u \bar{\partial}_x^\alpha \eta dx dt \\ & = \int_0^T \int_G f \bar{\eta} dt, \end{aligned} \quad (21)$$

holds for all $\eta \in H_B^{m,1}(Q_T)$ satisfying $\eta(\cdot, T) = 0$.

3. Statements of the Main Results

The unique solvability of the problem is given by the following theorem.

Theorem 2. *There exists a positive real number γ_0 such that for each $\gamma > \gamma_0$, if $f \in L_2(Q, \sigma)$ for some real number σ , the problem (8)-(9) has a unique generalized solution u in the space $H_B^{m,1}(Q, \gamma + \sigma)$ and*

$$\|u\|_{H_B^{m,1}(Q, \gamma + \sigma)}^2 \leq C \|f\|_{L_2(Q, \sigma)}^2, \quad (22)$$

where C is a constant independent of u and f .

The following theorem states on the regularity of the generalized solution in weighted Sobolev spaces.

Theorem 3. *Let h be a positive integer and γ_0 be the number as in Theorem 2. Suppose that the function f satisfies the following conditions for some real number σ :*

- (i) $f_{t^k} \in L_2(Q, k\gamma_0 + \sigma)$, $k \leq h$,
- (ii) $f_{t^k}(x, 0) = 0$, $0 \leq k \leq h-1$.

Let $u \in H_B^{m,1}(Q, \gamma + \sigma)$ for some $\gamma > \gamma_0$ be the generalized solution of the problem (8)-(9). Then $u_{t^k} \in H_m^{2m,1}(Q, (k+2)\gamma + \sigma)$ for $k = 0, 1, \dots, h-1$ and

$$\sum_{k=0}^{h-1} \|u_{t^k}\|_{H_m^{2m,1}(Q, (k+2)\gamma + \sigma)}^2 \leq C \sum_{k=0}^h \|f_{t^k}\|_{L_2(Q, k\gamma_0 + \sigma)}^2, \quad (23)$$

where C is a constant independent of u and f .

The proofs of these theorems will be given in Section 4. The number γ_0 will be defined by formula (66). It is natural that this number should be chosen as small as possible.

The remainder of this section is devoted to construct the theorem on the asymptotic behaviour of the solution near the conical point.

Let $r = |x|$ and ω be an arbitrary local coordinate system on S^{n-1} . Let δ be a positive real constant. A differential operator

$$P(x, t, \partial_x) = \sum_{|\alpha| \leq l} p_\alpha(x, t) \partial_x^\alpha, \quad (24)$$

is called δ -admissible operator of order l near the conical point 0 if the coefficients $p_\alpha(x, t)$ are infinitely differentiable in $\bar{Q}$ and there is representation in a neighborhood U of the conical point 0:

$$p_\alpha(x, t) = r^{|\alpha|-l} p_\alpha^{(0)}(\omega, t) + r^{|\alpha|-l+\delta} p_\alpha^{(1)}(\omega, r, t), \quad (25)$$

where $p_\alpha^{(0)} \in C^\infty(\bar{\Omega} \times \mathbb{R}_+)$ and the functions $p_\alpha^{(1)}$ are infinitely differentiable functions in $\bar{\Omega} \times \mathbb{R}_+ \times \mathbb{R}_+$ such that

$$|(r\partial_r)^j \partial_\omega^\beta \partial_t^k p_\alpha^{(1)}(\omega, r, t)| < c_{j\beta k}, \quad (26)$$

for every multiindex β and every pair of nonnegative integers j, k . Here the constants $c_{j\beta k}$ do not depend on ω, r and t . The leading part $\mathcal{P}$ of the operator P at the point 0 is defined by

$$\mathcal{P}(x, t, \partial_x) = \sum_{|\alpha| \leq l} r^{|\alpha|-l} p_\alpha^{(0)}(\omega, t) \partial_x^\alpha. \quad (27)$$

It can be directly verified that the derivative ∂_x^α has the form

$$\partial_x^\alpha = r^{-|\alpha|} \sum_{p=0}^{|\alpha|} p_{\alpha j}(\omega, \partial_\omega) (r\partial_r)^j, \quad (28)$$

where $p_{\alpha j}(\omega, \partial_\omega)$ are differential operators of order $\leq |\alpha| - j$ with smooth coefficients on $\bar{\Omega}$. Thus the operator $\mathcal{P}(x, t, \partial_x)$ can be represented as

$$\mathcal{P}(x, t, \partial_x) = r^{-l} \sum_{j=0}^l p_j(\omega, t, \partial_\omega) (r\partial_r)^j. \quad (29)$$

For convenience we rewrite the operator $L(x, t, \partial_x)$ in the form

$$L = L(x, t, \partial_x) = \sum_{|\alpha| \leq 2m} a_\alpha(x, t) \partial_x^\alpha. \quad (30)$$

Let $\mathcal{L} = \mathcal{L}(x, t, \partial_x)$, $\mathcal{B}_j = \mathcal{B}_j(x, t, \partial_x)$ ($j = 1, \dots, m$) be the leading parts of $L(x, t, \partial_x)$, $B_j(x, t, \partial_x)$ at the point $x = 0$. Since the coefficients of the operators $L(x, t, \partial_x)$ and $B_j(x, t, \partial_x)$ are smooth, it is verified easily that

$$\begin{aligned} \mathcal{L}(x, t, \partial_x) &= \sum_{|\alpha|=2m} a_\alpha(0, t) \partial_x^\alpha, \mathcal{B}_j(x, t, \partial_x) \\ &= \sum_{|\alpha|=\mu_j} b_{j,\alpha}(0, t) \partial_x^\alpha, \end{aligned} \quad (31)$$

and the operators $L(x, t, \partial_x)$ and $B_j(x, t, \partial_x)$ are 1-admissible. Rewrite $\mathcal{L}(x, t, \partial_x)$, $\mathcal{B}_j(x, t, \partial_x)$ in the form

$$\begin{aligned} \mathcal{L}(x, t, \partial_x) &= r^{-2m} \mathcal{L}(\omega, t, \partial_\omega, r\partial_r), \mathcal{B}_j(x, t, \partial_x) \\ &= r^{-\mu_j} \mathcal{B}_j(\omega, t, \partial_\omega, r\partial_r). \end{aligned} \quad (32)$$

We introduce the operator

$$\begin{aligned} \mathcal{U}(\lambda, t) &= (\mathcal{L}(\omega, t, \partial_\omega, \lambda), \mathcal{B}_1(\omega, t, \partial_\omega, \lambda), \dots, \mathcal{B}_m(\omega, t, \partial_\omega, \lambda)), \\ &\quad (33) \end{aligned}$$

($\lambda \in \mathbb{C}$, $t \in \mathbb{R}_+$) of the parameter-dependent elliptic boundary value problem

$$\begin{aligned} \mathcal{L}(\omega, t, \partial_\omega, \lambda) u &= f \text{ in } \Omega, \\ \mathcal{B}_j(\omega, t, \partial_\omega, \lambda) u &= g_j \text{ on } \partial\Omega, \quad j = 1, \dots, m. \end{aligned} \quad (34)$$

This is a pencil of continuous operators from

$$\begin{aligned} \mathcal{X} &\equiv W_2^l(\Omega) \text{ into } \mathcal{Y} \\ &\equiv W_2^{l-2m}(\Omega) \times \prod_{j=1}^m W_2^{l-\mu_j-(1/2)}(\partial\Omega) \quad (l \geq 2m), \end{aligned} \quad (35)$$

depending polynomially on $\lambda \in \mathbb{C}$.

We mention now some well-known definitions [3]. Let $t_0 \in \mathbb{R}_+$ fixed. If $\lambda_0 \in \mathbb{C}$, $\varphi_0 \in \mathcal{X}$ such that $\varphi_0 \neq 0$, $\mathcal{U}(\lambda_0, t_0)\varphi_0 = 0$, then λ_0 is called an eigenvalue of $\mathcal{U}(\lambda, t_0)$ and $\varphi_0 \in \mathcal{X}$ is called an eigenvector corresponding to λ_0 . $\Lambda = \dim \ker \mathcal{U}(\lambda_0, t_0)$ is called the geometric multiplicity of the eigenvalue λ_0 .

If the elements $\varphi_1, \dots, \varphi_s$ of $\mathcal{X}$ satisfy the equations

$$\sum_{q=0}^{\sigma} \frac{1}{q!} \frac{\partial^{\beta}}{\partial \lambda^q} \mathcal{U}(\lambda, t_0)|_{\lambda=\lambda_0} \varphi_{\sigma-q} = 0 \text{ for } \sigma = 1, \dots, s, \quad (36)$$

then the ordered collection $\varphi_0, \varphi_1, \dots, \varphi_s$ is said to be a Jordan chain corresponding to the eigenvalue λ_0 of the length $s+1$. The rank of the eigenvector φ_0 (rank φ_0) is the maximal

length of the Jordan chains corresponding to the eigenvector φ_0 .

A canonical system of eigenvectors of $\mathcal{U}(\lambda_0, t_0)$ corresponding to the eigenvalue λ_0 is a system of eigenvectors $\varphi_{1,0}, \dots, \varphi_{\Lambda,0}$ such that rank $\varphi_{1,0}$ is maximal among the rank of all eigenvectors corresponding to λ_0 and rank $\varphi_{j,0}$ is maximal among the rank of all eigenvectors in any direct complement in $\ker \mathcal{U}(\lambda_0, t_0)$ to the linear span of the vectors $\varphi_{1,0}, \dots, \varphi_{j-1,0}$ ($j = 2, \dots, \Lambda$). The numbers $\kappa_j = \text{rank } \varphi_{j,0}$ ($j = 1, \dots, \Lambda$) are called the partial multiplicities and the sum $\kappa = \kappa_1 + \dots + \kappa_\Lambda$ is called the algebraic multiplicity of the eigenvalue λ_0 .

The eigenvalue of λ_0 is called simple if its algebraic multiplicity is equal to one.

For each fixed $t \in \mathbb{R}_+$ the set of all complex number λ such that $\mathcal{U}(\lambda, t)$ is not invertible is called the spectrum of $\mathcal{U}(\lambda, t)$. It is known that the spectrum of $\mathcal{U}(\lambda, t)$ is an enumerable set of its eigenvalues (see [3, Theorem 5.2.1]). Moreover, there are constants δ, R such that $\mathcal{U}(\lambda, t)$ is invertible for all $t \in \mathbb{R}_+$ and all λ in the set

$$\mathcal{D} := \{\lambda \in \mathbb{C} : |\operatorname{Re} \lambda| \leq \delta |\operatorname{Im} \lambda|, |\lambda| \geq R\}, \quad (37)$$

(see [3, Theorem 3.6.1]).

To receive asymptotic formulas of the solutions with the coefficients regular with respect to the variable t we require later that eigenvalues and eigenvectors of the pencil $\mathcal{U}(\lambda, t)$ satisfy the following assumption.

Let l_1, l_2 be nonnegative integers, and let β_1, β_2 be real numbers such that $l_1 - \beta_1 < l_2 - \beta_2$. We say that the assumption (H) for numbers $l_1, l_2, \beta_1, \beta_2$ is fulfilled if the following conditions are satisfied.

(i) The lines $\operatorname{Re} \lambda = -\beta_i + l_i - n/2$ ($i = 1, 2$) do not contain eigenvalues of the pencil $\mathcal{U}(\lambda, t)$, and the strip $-\beta_1 + l_1 - n/2 < \operatorname{Re} \lambda < -\beta_2 + l_2 - n/2$ contains the eigenvalues $\lambda_\mu(t)$, $\mu = 1, \dots, N$, with the geometric multiplicities Λ_μ and the partial multiplicities $\kappa_{\mu,k}$, $\mu = 1, \dots, N$, $k = 1, \dots, \Lambda_\mu$, not depending on $t \in \mathbb{R}_+$. These eigenvalues are smooth functions on $\mathbb{R}_+$.

(ii) A canonical system

$$\varphi_{k,s}^{(\mu)}(\omega, t), \quad k = 1, \dots, \Lambda_\mu, \quad s = 1, \dots, \kappa_{\mu,k}, \quad (38)$$

of Jordan chains of $\mathcal{U}(\lambda, t)$ corresponding to the eigenvalue $\lambda_\mu(t)$ ($\mu \in \{1, \dots, N\}$) can be chosen, which consists of functions that are smooth for $t \in \mathbb{R}_+$ for all $\omega \in \bar{\Omega}$.

Theorem 4. Let h be a positive integer. Let ϵ, β be real numbers such that $0 \leq \epsilon < 1/2$, $0 < \beta \leq m$ and $\epsilon + n/2, \beta + n/2$ are not integers in the case $m \geq n/2$. Suppose that the assumptions of Theorem 3 and the assumption (H) for $l_1 = l_2 = 2m$, $\beta_1 = m + \epsilon$, $\beta_2 = \beta$ are fulfilled. Let $u \in H^{m,1}(Q, \gamma)$ ($\gamma > \gamma_0$) be the generalized solution of the problem (8)-(9). Suppose further

that the operators $L(x, t, \partial_x)$ and $B_j(x, t, \partial_x)$ are $(m + \epsilon - \beta)$ -admissible near the origin 0. Then,

(i) for the case $m < n/2$, the solution u admits the decomposition

$$u(x, t) = \sum_{\mu=1}^N \sum_{k=1}^{\Lambda_\mu} \sum_{s=0}^{\kappa_{\mu,k}-1} c_{\mu,k,s}(t) r^{\lambda_\mu(t)} \times \sum_{\sigma=0}^s \frac{1}{\sigma!} (\ln r)^\sigma \varphi_{k,s}^{(\mu)}(\omega, t) + w(x, t), \quad (39)$$

where $w, c_{\mu,k,s}$ are functions satisfying $w_{t^p} \in V_{2,\beta}^{2m,0}(Q, (p+2)\gamma + \sigma)$, $(c_{\mu,k,s})_{t^p} \in L_2(\mathbb{R}_+^*, (p+2)\gamma + \sigma)$ for $p = 0, \dots, h$,

(ii) for the case $m \geq n/2$, we assume further that if $\lambda_k(t) = q$ is integer for some $t \in \mathbb{R}_+$ and some k , $1 \leq k \leq N$, then $\lambda_k(t) = q$ for all $t \in \mathbb{R}_+$; then the solution u admits the decomposition

$$u(x, t) = \sum_{|\alpha| \leq 2m-\ell-1} c_\alpha(t) x^\alpha + \sum_{k=2m-\ell}^{2m-\ell_1-1} r^k \sum_{s=0}^{\kappa_k} \frac{1}{s!} (\ln r)^s \varphi_{k,s}(\omega, t) + \sum_{\mu=1}^N \sum_{k=1}^{\Lambda_\mu} \sum_{s=0}^{\kappa_{\mu,k}-1} c_{\mu,k,s}(t) r^{\lambda_\mu(t)} \times \sum_{\sigma=0}^s \frac{1}{\sigma!} (\ln r)^\sigma \varphi_{k,s}^{(\mu)}(\omega, t) + w(x, t), \quad (40)$$

where $w, c_\alpha, c_{\mu,k,s}$ are functions satisfying $w_{t^p} \in V_{2,\beta}^{2m,0}(Q, (p+2)\gamma + \sigma)$, $(c_\alpha)_{t^p}, (c_{\mu,k,s})_{t^p} \in L_2(\mathbb{R}_+^*, (p+2)\gamma + \sigma)$, for $p = 0, \dots, h$, and ℓ_1 is the integer with $\ell_1 - n/2 < \beta < \ell_1 + 1 - n/2$, $\kappa_k = 0$ if k is not an eigenvalue of $\mathcal{U}(\lambda, t)$; otherwise κ_k is the maximal partial multiplicity of the eigenvalue k .

4. Proofs of Theorems 2 and 3

First, let us introduce some more notations. For functions u, v defined in G and $k \in \mathbb{N}$, we set

$$|u|_{k,G} = \left(\int_G \sum_{|\alpha|=k} |\partial^\alpha u|^2 dx \right)^{1/2}, \quad (u, v)_G = \int_G u \bar{v} dx. \quad (41)$$

For functions u and v defined in Q , we set

$$|u|_{k,Q_\tau} = \left(\int_0^\tau |u(t)|_{k,G}^2 dt \right)^{1/2},$$

$$B_t(t, u, v) = \sum_{|\alpha|, |\beta| \leq m} \int_G \frac{\partial a_{\alpha\beta}}{\partial t}(t) \partial^\beta u(t) \overline{\partial^\alpha v(t)} dx, \quad (42)$$

$$B_t^\tau(u, v) = \int_0^\tau B_t(t, u, v) dt.$$

Here and hereafter, we use $u(t)$ instead of $u(\cdot, t)$ for the shortness.

To prove Theorem 2, it is needed to introduce the Gronwall-Bellman and interpolation inequalities stated in the following lemmas.

Lemma 5. (see [14, Lemma 3.1])

Assume u, α, β are real-valued continuous on an interval $[a, b]$, β is nonnegative and integrable on $[a, b]$ and α is nondecreasing satisfying

$$u(\tau) \leq \alpha(\tau) + \int_a^\tau \beta(t) u(t) dt \quad \forall a \leq \tau \leq b. \quad (43)$$

Then

$$u(\tau) \leq \alpha(\tau) \exp \left(\int_a^\tau \beta(t) dt \right) \quad \forall a \leq \tau \leq b. \quad (44)$$

Lemma 6. (see [15, Lemma 4.14])

For each positive real number ϵ and each integer $j, 0 < j < m$, there exists a positive real number $C = C(G, m, \epsilon)$ which is dependent only on G, m , and ϵ such that the inequality

$$|u|_{j,G}^2 \leq \epsilon |u|_{m,G}^2 + C |u|_{0,G}^2, \quad (45)$$

holds for all $u \in H^m(G)$.

Proof of Theorem 2. The theorem is proved by repeating almost word for word the proof of Theorem 3.3 of [7]. Here we present the proof of the existence to show that the restriction of negativeness of σ in that theorem can be omitted.

Let $\{\varphi_k\}_{k=1}^\infty$ be a basis of $H_B^m(G)$ which is orthonormal in $L_2(G)$. Put

$$u^N(x, t) = \sum_{k=1}^N c_k^N(t) \varphi_k(x), \quad (46)$$

where $(c_k^N(t))_{k=1}^N$ are the solution of the system of the following ordinary differential equations of second order:

$$\left(u_{tt}^N(t), \varphi_l \right)_G + B(t, u^N, \varphi_l) = (f(t), \varphi_l)_G, \quad l = 1, \dots, N, \quad (47)$$

with the initial conditions

$$c_k^N(0) = \frac{dc_k^N}{dt}(0) = 0, \quad k = 1, \dots, N. \quad (48)$$

Let us multiply (47) by $(d/dt)c_k^N(t)$. Take the sum with respect to l from 1 to N to receive

$$\left(u_{tt}^N(t), u_t^N(t) \right)_G + B(\tau, u^N, u_t^N) = (f(t), u_t^N(t))_G. \quad (49)$$

Now adding this equality to its complex conjugate with noting that

$$\overline{B(\tau, u, v)} = B(\tau, v, u), \quad (50)$$

by the formally self-adjointness of the operator L , then integrating the obtained equality with respect to t from 0 to τ with using the integration by parts and (48), we arrive at

$$\left| u_t^N(\tau) \right|_{0,G}^2 + B(\tau, u^N, u^N) = B_t^\tau(u^N, u^N) + 2 \operatorname{Re}(f, u_t^N)_{Q_\tau}. \quad (51)$$

Noting that

$$\left| u^N(\tau) \right|_{0,G}^2 = 2 \operatorname{Re}(u^N, u_t^N)_{Q_\tau}, \quad (52)$$

we have from (51) that

$$\begin{aligned} & \left| u_t^N(\tau) \right|_{0,G}^2 + B_0(\tau, u^N, u^N) + \rho \left| u(\tau) \right|_{0,G}^2 \\ &= B_t^\tau(u^N, u^N) + 2\rho \operatorname{Re}(u^N, u_t^N)_{Q_\tau} \\ &\quad - \sum_{\substack{|\alpha|, |\beta| \leq m \\ |\alpha|+|\beta| < 2m-1}} \int_G a_{\alpha\beta}(\tau) \partial^\beta u^N(\tau) \overline{\partial^\alpha u^N(\tau)} dx \\ &\quad + 2 \operatorname{Re}(f, u_t^N)_{Q_\tau}. \end{aligned} \quad (53)$$

Now we give estimations for the terms of (53). Firstly, by (2), we see that the left-hand side of (53) is greater than

$$\left| u_t^N(\tau) \right|_{0,G}^2 + \mu_0 \left| u^N(\tau) \right|_{m,G}^2 + \rho \left| u(\tau) \right|_{0,G}^2. \quad (54)$$

We write B_t^τ as the sum of the two following terms:

$$\begin{aligned} I_1 &= \sum_{|\alpha|=|\beta|=m} \int_{Q_\tau} \frac{\partial a_{\alpha\beta}}{\partial t} \partial^\beta u^N \overline{\partial^\alpha u^N} dx dt, \\ I_2 &= \sum_{\substack{|\alpha|, |\beta| \leq m \\ |\alpha|+|\beta| \leq 2m-1}} \int_{Q_\tau} \frac{\partial a_{\alpha\beta}}{\partial t} \partial^\beta u^N \overline{\partial^\alpha u^N} dx dt. \end{aligned} \quad (55)$$

Put

$$\begin{aligned} \mu_1 &= \sup \left\{ \left| \frac{\partial a_{\alpha\beta}}{\partial t}(x, t) \right| : |\alpha| = |\beta| = m, (x, t) \in \overline{Q} \right\}, \\ m' &= \sum_{|\alpha|=m} 1. \end{aligned} \quad (56)$$

Then, by the Cauchy inequality, we have

$$\begin{aligned} |I_1| &\leq \mu_1 \sum_{|\alpha|=|\beta|=m} \frac{1}{2} \left(\left| \partial^\beta u^N \right|_{0,Q_\tau}^2 + \left| \partial^\alpha u^N \right|_{0,Q_\tau}^2 \right) \\ &\leq m' \mu_1 \left| u^N \right|_{m,Q_\tau}^2. \end{aligned} \quad (57)$$

By the Cauchy inequality and the interpolation inequality (45), for an arbitrary positive number ϵ_1 , we have

$$\left| I_2 \right| \leq \epsilon_1 \left| u^N \right|_{m,Q_\tau}^2 + C_1 \left| u^N \right|_{0,Q_\tau}^2, \quad (58)$$

where $C_1 = C_1(\epsilon_1)$ is a nonnegative constant independent of u^N , f , and τ . Now using again the Cauchy and interpolation inequalities, for an arbitrary positive number ϵ_2 with $\epsilon_2 < \mu_0$, it holds that

$$\begin{aligned} & \left| \sum_{\substack{|\alpha|, |\beta| \leq m \\ |\alpha|+|\beta| < 2m-1}} \int_G a_{\alpha\beta} \partial^\beta u^N \overline{\partial^\alpha u^N} dx \right| \\ & \leq \epsilon_2 \left| u^N(\tau) \right|_{m,G}^2 + C_2 \left| u^N(\tau) \right|_{0,G}^2, \end{aligned} \quad (59)$$

where $C_2 = C_2(\epsilon_2)$ is a nonnegative constant independent of u^N , f , and τ . Also by Cauchy inequality we have

$$\begin{aligned} \left| 2\rho \operatorname{Re}(u^N, u_t^N)_{Q_\tau} \right| &\leq \frac{(\mu_0 - \epsilon_2) \rho^2}{m' \mu_1 + \epsilon_1} \left| u^N \right|_{0,Q_\tau}^2 \\ &\quad + \frac{m' \mu_1 + \epsilon_1}{\mu_0 - \epsilon_2} \left| u_t^N \right|_{0,Q_\tau}^2. \end{aligned} \quad (60)$$

Now, to deal with the last term of (53), let us consider first the case $\sigma \geq 0$. In this case, we use the following inequality:

$$\left| 2 \operatorname{Re}(f, u_t^N)_{Q_\tau} \right| \leq \epsilon_3 \left| u_t^N \right|_{0,Q_\tau}^2 + \frac{1}{\epsilon_3} \left| f \right|_{0,Q_\tau}^2, \quad (61)$$

where $\epsilon_3 > 0$ arbitrary. Combining the above estimations we get from (53) that

$$\begin{aligned} & \left| u_t^N(\tau) \right|_{0,G}^2 + (\mu_0 - \epsilon_2) \left| u^N(\tau) \right|_{m,G}^2 + (\rho - C_2) \left| u^N(\tau) \right|_{0,G}^2 \\ & \leq (m' \mu_1 + \epsilon_1) \left| u^N \right|_{m,Q_\tau}^2 + \left(C_1 + \frac{(\mu_0 - \epsilon_2) \rho^2}{m' \mu_1 + \epsilon_1} \right) \left| u^N \right|_{0,Q_\tau}^2 \\ & \quad + \left(\frac{m' \mu_1 + \epsilon_1}{\mu_0 - \epsilon_2} + \epsilon_3 \right) \left| u_t^N \right|_{0,Q_\tau}^2 + \frac{1}{\epsilon_3} \left| f \right|_{0,Q_\tau}^2. \end{aligned} \quad (62)$$

Now fix ϵ_1, ϵ_2 and consider the function

$$g(\rho) = \frac{C_1 + (\mu_0 - \epsilon_2) \rho^2 / (m' \mu_1 + \epsilon_1)}{\rho - C_2} \quad \text{for } \rho > C_2. \quad (63)$$

We see that

$$\frac{dg}{d\rho} = \frac{A\rho^2 - 2AC_2\rho - C_1}{(\rho - C_2)^2} \quad \text{with } A = \frac{(\mu_0 - \epsilon_2)}{m' \mu_1 + \epsilon_1}. \quad (64)$$

We see that the function g has a unique minimum at

$$\rho_0 = \rho_0(\epsilon_1, \epsilon_2) = C_2 + \sqrt{C_2^2 + \frac{C_1}{A}} > C_2. \quad (65)$$

Let us denote

$$\gamma_0 = \frac{1}{2} \inf_{\substack{\epsilon_1 > 0 \\ 0 < \epsilon_2 < \mu_0}} \max \left\{ \frac{m' \mu_1 + \epsilon_1}{\mu_0 - \epsilon_2}, g(\rho_0) \right\}. \quad (66)$$

Now we take real numbers γ, γ_1 arbitrarily satisfying $\gamma_0 < \gamma_1 < \gamma$. Then there are positive real numbers ϵ_1, ϵ_2 ($\epsilon_2 < \mu_0$), ρ ($\rho > C_2(\epsilon_1, \epsilon_2)$), and ϵ_3 such that

$$\begin{aligned} \frac{m' \mu_1 + \epsilon_1}{\mu_0 - \epsilon_2} + \epsilon_3 &< 2\gamma_1, \\ \frac{C_1(\epsilon_1, \epsilon_2) + (\mu_0 - \epsilon_2) \rho^2 / (m' \mu_1 + \epsilon_1)}{\rho - C_2(\epsilon_1, \epsilon_2)} &< 2\gamma_1. \end{aligned} \quad (67)$$

From now to the end of the present proof, we fix such constants $\epsilon_1, \epsilon_2, \epsilon_3$, and ρ and denote by $\|u^N(\tau)\|_G^2$ the left-hand side of (62). It follows from (62) and (67) that

$$\begin{aligned} \|u^N(\tau)\|_G^2 &\leq 2\gamma_1 \int_0^\tau \|u(t)\|_G^2 dt \\ &\quad + \frac{1}{\epsilon_3} \int_0^\tau |f(t)|_{0,G}^2 dt \quad \forall \tau \geq 0. \end{aligned} \quad (68)$$

By the Gronwall-Bellman inequality (44), we deduce from (68) that

$$\begin{aligned} \|u^N(\tau)\|_G^2 &\leq \frac{1}{\epsilon_3} e^{2\gamma_1 \tau} \int_0^\tau |f(t)|_{0,G}^2 dt \\ &\leq \frac{1}{\epsilon_3} e^{2(\gamma_1 + \sigma)\tau} \|f\|_{L_2(Q,\sigma)}^2, \end{aligned} \quad (69)$$

for all $\tau \geq 0$. Here we used the fact that, for $\sigma \geq 0$,

$$\begin{aligned} \int_0^\tau |f(\cdot, t)|_{0,G}^2 dt &= e^{2\sigma\tau} \int_0^\tau |e^{-\sigma\tau} f(\cdot, t)|_{0,G}^2 dt \\ &\leq e^{2\sigma\tau} \|f\|_{L_2(Q,\sigma)}^2. \end{aligned} \quad (70)$$

In the case of $\sigma < 0$, instead of (61), we give the following inequality

$$\begin{aligned} &|2 \operatorname{Re}(f, u_t^N)_{Q_\tau}| \\ &= |2 \operatorname{Re}(e^{-\sigma t} f, e^{\sigma t} u_t^N)_{Q_\tau}| \\ &\leq \epsilon_3 |e^{\sigma t} u_t^N|_{0,Q_\tau}^2 + \frac{1}{\epsilon_3} |e^{-\sigma t} f|_{0,Q_\tau}^2 \\ &\leq \epsilon_3 |u_t^N|_{0,Q_\tau}^2 + \frac{1}{\epsilon_3} |e^{-\sigma t} f|_{0,Q_\tau}^2 \quad \forall \tau \geq 0. \end{aligned} \quad (71)$$

Thus, by repeating the above arguments we receive (68) with the last term replaced by the last term of (71), and, therefore, we also get (69) for every real number σ .

Now multiplying both sides of this inequality by $e^{-2(\gamma+\sigma)\tau}$, then integrating them with respect to τ from 0 to ∞ , we arrive at

$$\|u^N\|_{Q,\gamma+\sigma}^2 \leq \frac{1}{\epsilon_3} \|f\|_{L_2(Q,\sigma)}^2, \quad (72)$$

where we used the notation

$$\|u^N\|_{Q,\gamma+\sigma}^2 = \int_0^\infty e^{-2(\gamma+\sigma)\tau} \|u^N(\tau)\|_G^2 d\tau. \quad (73)$$

It is clear that $\|\cdot\|_{Q,\gamma+\sigma}$ is a norm in $H_B^{m,1}(Q, \gamma + \sigma)$ which is equivalent to the norm $\|\cdot\|_{H_B^{m,1}(Q,\gamma+\sigma)}$. Thus, it follows from (72) that

$$\|u^N\|_{H_B^{m,1}(Q,\gamma+\sigma)}^2 \leq C \|f\|_{L_2(Q,\sigma)}^2, \quad (74)$$

where C is a constant independent of f and N .

From the inequality (74), by standard weak convergence arguments (see, e.g., [16, Ch. 7]), we can conclude that the sequence $\{u^N\}_{N=1}^\infty$ possesses a subsequence convergent to a function $u \in H_B^{m,1}(Q, \gamma + \sigma)$ which is a generalized solution of problem (8)-(9). Moreover, it follows from (74) that the inequality (22) holds. $\square$

Now we are going to prove Theorem 3. First, we give some needed auxiliary lemmas. The first lemma deals with the regularity of the solution with respect to time variable. It is proved by repeating almost word for word the proof of Theorem 3.4 of [7] with noting that, as in Theorem 2, the assumption $\sigma \geq 0$ in [7] can be removed.

Lemma 7. Suppose that all the assumptions of Theorem 3 are fulfilled. Then $u_{t^k} \in H_B^{m,1}(Q, (k+1)\gamma + \sigma)$ for $k = 0, 1, \dots, h$ and

$$\sum_{k=0}^h \|u_{t^k}\|_{H_B^{m,1}(Q, (k+1)\gamma + \sigma)}^2 \leq C \sum_{k=0}^h \|f_{t^k}\|_{L_2(Q, k\gamma + \sigma)}^2, \quad (75)$$

where C is a constant independent of u and f .

From the proof of [12, Lemma 5.3] we have the following lemma.

Lemma 8. Let $f \in H_m^0(G)$, $g_j \in H_m^{2m-\mu_j-1/2}(\Gamma)$, $j = 1, \dots, m$, and $t_0 \in \mathbb{R}_+^*$. Suppose that $u \in H_B^m(G) \cap H_{\text{loc}}^{2m}(\overline{G} \setminus \{0\})$ is a solution of the following problem:

$$\begin{aligned} L(x, t_0, \partial) u &= f \text{ in } G, \\ B_j(x, t_0, \partial) u &= g_j \text{ on } \Gamma, \quad j = 1, \dots, m. \end{aligned} \quad (76)$$

Then $u \in H_m^{2m}(G)$ and

$$\begin{aligned} &\|u\|_{H_m^{2m}(G)}^2 \\ &\leq C \left(\|f\|_{H_m^0(G)}^2 + \sum_{j=1}^m \|g_j\|_{H_m^{2m-\mu_j-1/2}(\Gamma)}^2 + \|u\|_{H_B^m(G)}^2 \right), \end{aligned} \quad (77)$$

where the constant C is independent of u , f , and t_0 .

Proof of Theorem 3. According to Lemma 7 we have

$$u_{t^k} \in H_B^{m,1}(Q, (k+1)\gamma + \sigma), \quad k \leq h. \quad (78)$$

Moreover, as in proof of Theorem 4.1 of [7], we have

$$\begin{aligned} u_{t^k}(\cdot, t) &\in H_{\text{loc}}^{2m}(\overline{G} \setminus \{0\}) \text{ for a.e. } t \in \mathbb{R}_+^* \\ &\text{and all } k \leq h-1. \end{aligned} \quad (79)$$

Now we prove the theorem by induction on h . By (78), $u_{tt} \in L_2(Q, 2\gamma + \sigma)$. Thus, from (21) we have

$$B(t, u, \eta) = (f(t) - u_{tt}(t), \eta), \quad (80)$$

for all $\eta \in H_B^m(G)$ and a.e. $t \in \mathbb{R}_+^*$. Since $f_1(t) := f(t) - u_{tt}(t) \in L_2(G) \subset H_m^0(G)$ for a.e. $t \in \mathbb{R}_+^*$, by Lemma 8, we get from (80) that $u(t) \in H_m^{2m}(G)$ for a.e. $t \in \mathbb{R}_+^*$ and

$$\|u(t)\|_{H_m^{2m}(G)}^2 \leq C \left(\|f_1(t)\|_{L_2(G)}^2 + \|u(t)\|_{H_m^m(G)}^2 \right), \quad (81)$$

where C is a constant independent of u , f_1 , and t . Now multiplying both sides of (81) with $e^{-2(2\gamma+\sigma)t}$, then integrating with respect to t from 0 to ∞ and using estimates from Lemma 7, we obtain

$$\|u\|_{H_m^{2m,1}(Q, 2\gamma+\sigma)}^2 \leq C \|f\|_{L_2(Q, \sigma)}^2, \quad (82)$$

where C is a constant independent of u and f . Hence, the theorem is valid for $h = 1$.

Assume that the theorem is true for some nonnegative $h-2$. We will prove it for $h-1$. Differentiating $h-1$ times both sides of (80) with respect to t we have

$$\begin{aligned} B(t, u_{t^{h-1}}, \eta) &= (f_{t^{h-1}}(t), \eta) - (u_{t^{h+1}}(t), \eta) \\ &\quad - \sum_{k=0}^{h-2} \binom{h}{k} B_{t^{h-k-1}}(t, u_{t^k}, \eta), \end{aligned} \quad (83)$$

for all $\eta \in H_B^m(G)$, a.e. $t \in \mathbb{R}_+^*$. From (6) it follows that

$$B_{t^k}(t, v, \eta) = (L_{t^k}(x, t, \partial) v, \eta), \quad (84)$$

for all $v \in H_B^m(G) \cap H_m^{2m}(G)$ and $\eta \in H_B^m(G)$. Thus, from (83) we deduce

$$B(t, u_{t^h}, \eta) = (F_h(\cdot, t), \eta), \quad (85)$$

for all $\eta \in H_B^m(G)$ and a.e. $t \in \mathbb{R}_+$, where

$$\begin{aligned} F_h &= f_{t^h}(\cdot, t) - u_{t^{h+2}}(\cdot, t) \\ &\quad - \sum_{k=0}^{h-1} \binom{h}{k} L_{t^{h-k}}(\cdot, t, D) u_{t^k} \in H_m^0(G). \end{aligned} \quad (86)$$

By the induction assumption, it holds that

$$\begin{aligned} u_{t^k} &\in H_m^{2m,1}(Q, (k+2)\gamma + \sigma) \subset H_m^{2m,1}(Q, (h+1)\gamma + \sigma), \\ k &= 0, \dots, h-2. \end{aligned} \quad (87)$$

Moreover,

$$f_{t^{h-1}} \in L_2(Q, (h-1)\gamma + \sigma) \subset L_2(Q, (h+1)\gamma + \sigma) \quad (88)$$

by the assumption of the theorem, and

$$u_{t^{h+1}} \in L_2(Q, (h+1)\gamma + \sigma) \quad (89)$$

by Lemma 7. Thus, for a.e. $t \in \mathbb{R}_+^*$, we have $\tilde{f}(t) \in H_m^0(G)$, $\tilde{g}(t) \in H_\alpha^{j-(1/2)}(\Gamma)$, and

$$\begin{aligned} &\|\tilde{f}(t)\|_{H_m^0(G)}^2 \\ &\leq C \left(\|f_{t^{h-1}}(t)\|^2 + \|u_{t^{h+2}}(t)\|_{L_2(G)}^2 + \sum_{k=0}^{h-2} \|u_{t^k}(t)\|_{H_m^{2m}(G)}^2 \right), \end{aligned} \quad (90)$$

where C is the constant independent of u , f and t . Now we can repeat the arguments above to conclude that $u_{t^{h-1}} \in H_m^{2m,1}(Q, (h+1)\gamma + \sigma)$ with the estimate (23) for $k = h-1$. The proof is completed. $\square$

5. The Proof of Theorem 4

Let us first give some auxiliary lemmas.

Lemma 9. Let l be a nonnegative integer, $l \geq 2m$, and let β_1, β_2 be real numbers, $\beta_1 > \beta_2$. Suppose that the assumption (H) is fulfilled for the numbers $l_1 = l_2 = l$, β_1, β_2 . Let $h \in \mathbb{N}$, let $\gamma_0 \leq \gamma_1 \leq \dots \leq \gamma_h$ be real numbers, and let f and g_j be functions satisfying $f_{t^p} \in V_{2,\beta_2}^{l-2m,0}(Q, \gamma_p)$, $(g_j)_{t^p} \in V_{2,\beta_2}^{l-\mu_j-(1/2),0}(S, \gamma_p)$ for $p = 0, \dots, h$. Suppose that $u \in V_{2,\beta_1}^{l,0}(Q, \gamma_0)$ is a solution of the problem

$$\begin{aligned} \mathcal{L}(t, \partial_x) u &= f \text{ in } Q, \\ \mathcal{B}_j(t, \partial_x) u &= g_j \text{ on } S, \quad j = 1, \dots, m. \end{aligned} \quad (91)$$

Then u admits the following representation:

$$\begin{aligned} u(x, t) &= \sum_{\mu=1}^N \sum_{k=1}^{\Lambda_\mu} \sum_{s=0}^{\kappa_{\mu,k}-1} c_{\mu,k,s}(t) r^{\lambda_\mu(t)} \\ &\quad \times \sum_{\sigma=0}^s \frac{1}{\sigma!} (\ln r)^\sigma \varphi_{k,s}^{(\mu)}(\omega, t) + w(x, t), \end{aligned} \quad (92)$$

where w and $c_{\mu,k,s}$ are functions satisfying $w_{t^p} \in V_{2,\beta_2}^{l,0}(Q, \gamma_p)$, $(c_{\mu,k,s})_{t^p} \in L_2(\mathbb{R}_+^*, \gamma_p)$ for $p = 0, \dots, h$.

Proof. From the proof of Lemma 4.5 of [13] (see also [17, Lemma 4.1]), it is known that, for each fixed $t \in \mathbb{R}_+^*$, the solution $u(x, t)$ admits the representation (92) and the following inequality

$$\begin{aligned} &\max \left(\|w_{t^p}(\cdot, t)\|_{V_{2,\beta_2}^l(G)}^2, |(c_{\mu,k,s})_{t^q}(t)| \right) \\ &\leq C \left(\sum_{q=0}^p \|f_{t^q}(\cdot, t)\|_{V_{2,\beta_2}^{l-2m}(G)}^2 \right. \\ &\quad \left. + \sum_{j=1}^m \sum_{q=0}^p \|(g_j)_{t^q}(\cdot, t)\|_{V_{2,\beta_2}^{l-\mu_j-1/2}(\Gamma)}^2 \right), \end{aligned} \quad (93)$$

holds for all $t \in \mathbb{R}_+^*$, $p = 0, 1, \dots, h$, where C is a constant independent of u , f , g_j , and t . Now multiplying both sides of (93) by $e^{-2\gamma_p t}$, then integrating with respect to t from 0 to ∞ , we see that $w_{t^p} \in V_{2,\beta_2}^{1,0}(Q, \gamma_p)$, $(c_{\mu,k,s})_{t^p} \in L_2(\mathbb{R}_+^*, \gamma_p)$. The lemma is proved. $\square$

By applying Lemma 9 and repeating the arguments in the proof of [13, Lemma 4.6], we get the following lemma.

Lemma 10. Suppose that all assumptions of Lemma 9 are fulfilled. Suppose further that the operators $L(x, t, \partial_x)$ and $B_j(x, t, \partial_x)$ are δ -admissible near the origin 0, where $\delta = \beta_1 - \beta_2$. Let $u \in V_{2,\beta_1}^{1,0}(Q, \gamma_0)$ be a solution of the problem

$$\begin{aligned} L(x, t, \partial_x) u &= f \text{ in } Q, \\ B_j(x, t, \partial_x) u &= g_j \text{ on } S, \quad j = 1, \dots, m. \end{aligned} \quad (94)$$

Then u admits a representation of the form (92).

The following lemma follows directly from the proof of [13, Lemma 4.7].

Lemma 11. Let $h \in \mathbb{N}$, and let $\gamma_0 \leq \gamma_1 \leq \dots \leq \gamma_h$ be real numbers. Let

$$\begin{aligned} f &= r^{\lambda_0(t)-2m} \tilde{f}, \\ g_j &= r^{\lambda_0(t)-\mu_j} \tilde{g}_j, \quad j = 1, \dots, m, \end{aligned} \quad (95)$$

where $\tilde{f}$ and $\tilde{g}_j$ are given functions defined on $\Omega \times \mathbb{R}_+^*$, $\partial\Omega \times \mathbb{R}_+^*$, respectively, satisfying $(\tilde{f})_{t^p} \in L_2(\Omega \times \mathbb{R}_+^*, \gamma_p)$, $(\tilde{g}_j)_{t^p} \in L_2(\partial\Omega \times \mathbb{R}_+^*, \gamma_p)$, $j = 1, \dots, m$, $p = 0, \dots, h$. Suppose that if $\lambda_0(t)$ is an eigenvalue of $\mathcal{U}(\lambda, t)$ for some t , then it is an eigenvalue of $\mathcal{U}(\lambda, t)$ for all $t \in \mathbb{R}_+^*$ with the geometric multiplicity and the partial multiplicities not depending on $t \in \mathbb{R}_+^*$. Then there exists a solution u of the problem (91) which has the form

$$u = r^{\lambda_0(t)} \sum_{\sigma=0}^{\kappa} \frac{1}{\sigma!} (\ln r)^\sigma u_{\kappa-\sigma}, \quad (96)$$

where u_σ are functions defined on $\Omega \times \mathbb{R}_+^*$ satisfying $(u_\sigma)_{t^p} \in L_2(\mathbb{R}_+^*, H^{2m}(\Omega), \gamma_p)$, $\sigma = 0, \dots, \kappa$. Here $\kappa = 0$ if $\lambda_0(t)$ is not an eigenvalue of $\mathcal{U}(\lambda, t)$; otherwise κ is the maximal partial multiplicity of $\lambda_0(t)$.

Proof of Theorem 4. According to Theorem 3, we have

$$u_{t^p} \in H_m^{2m,1}(Q, (k+2)\gamma + \sigma) \subset H_{m+\epsilon}^{2m,1}(Q, (k+2)\gamma + \sigma), \quad (97)$$

for $p = 0, \dots, h-1$.

Rewrite (8) in the form

$$Lu = f_1 := f - u_{tt} \text{ in } Q, \quad (98)$$

$$B_j u = 0 \text{ on } S, \quad j = 1, \dots, m. \quad (99)$$

Since $u_{t^{p+2}} \in L_2(Q, (p+2)\gamma + \sigma)$ by (75) and $f_{t^p} \in L_2(Q, p\gamma + \sigma)$ by the assumption, we have

$$\begin{aligned} (f_1)_{t^p} &\in L_2(Q, (p+2)\gamma + \sigma) \\ &\equiv V_{2,0}^{0,0}(Q, (p+2)\gamma + \sigma) \subset V_{2,\beta}^{0,0}(Q, (p+2)\gamma + \sigma), \end{aligned} \quad (100)$$

for $p = 0, \dots, h-1$.

Now the assertions of the theorem are obtained by applying Lemma 10 and repeating almost word for word the proof of [13, Theorem 4.8]. $\square$
