This paper gives a new prediction-correction method based on the dynamical system of differential-algebraic equations for the smallest generalized eigenvalue problem. First, the smallest generalized eigenvalue problem is converted into an equivalent-constrained optimization problem. Second, according to the Karush-Kuhn-Tucker conditions of this special equality-constrained problem, a special continuous dynamical system of differential-algebraic equations is obtained. Third, based on the implicit Euler method and an analogous trust-region technique, a prediction-correction method is constructed to follow this system of differential-algebraic equations to compute its steady-state solution. Consequently, the smallest generalized eigenvalue of the original problem is obtained. The local superlinear convergence property for this new algorithm is also established. Finally, in comparison with other methods, some promising numerical experiments are presented.

1. Introduction

In this paper, we consider the smallest generalized eigenvalue problem, which is often encountered in engineering applications such as automatic control, dynamical analysis of structure, electronic structure calculations, and quantum chemistry (see [1, 2] and references therein). For this old and active problem, recently, Gao et al. gave an interesting continuous projected method [3, 4]. This article follows this line and gives a new prediction-correction method based on the dynamical system of differential-algebraic equations (DAEs) for this problem.

First, we convert the smallest eigenvalue problem into an equivalent equality-constrained optimization problem. Second, from the Karush-Kuhn-Tucker conditions of this optimization problem, we obtain a variant of the Rayleigh quotient gradient flow [5, 6], which is formulated by a system of DAEs. Third, applying the implicit Euler method [7], a projected technique [4, 8, 9], and a new time-stepping strategy to that dynamical system of DAEs, we construct a new prediction-correction method to compute a steady-state solution of that special dynamical system. Consequently, we obtain the smallest generalized eigenvalue of (A, B) . We also

establish the local superlinear convergence property for this new method. Last, in comparison with other methods, some promising numerical experiments are presented. Throughout this article, $\|\cdot\|$ denotes the Euclidean vector norm and the corresponding induced matrix norm.

2. Continuous Dynamical Model

The generalized eigenvalue problem (A, B) is to find a scalar λ and nonzero vector $x \in \mathbb{R}^n$ to satisfy

$$Ax = \lambda Bx, \quad (1)$$

where A and B are $n \times n$ real symmetric matrices and B is positive definite. Problem (1) can be converted to an equivalent equality-constrained optimization problem [4]:

$$\begin{aligned} \min_{x \in \mathbb{R}^n} \quad & x^T A x, \\ \text{s.t.} \quad & x^T B x = 1. \end{aligned} \quad (2)$$

If x^* is an optimal solution of problem (2), according to the Karush-Kuhn-Tucker conditions [10, p. 328], then there exists

a Lagrange multiplier λ^* such that the following conditions are satisfied at (x^*, λ^*) :

$$\begin{aligned} Ax^* - \lambda^* Bx^* &= 0, \\ (x^*)^T Bx^* &= 1. \end{aligned} \quad (3)$$

Therefore, the solution x^* of problem (2) is a generalized eigenvector of (A, B) .

Property 1 (Gao et al., 2008 [4]). If x^* is an optimal solution of problem (2) and λ^* is the corresponding Lagrange multiplier, then they satisfy the second-order optimality condition

$$(A - \lambda^* B) \succeq 0. \quad (4)$$

Furthermore, a local minimizer of (2) is also its global minimizer. If x^* is a global minimizer of (2), then it is an eigenvector associated with the smallest generalized eigenvalue of (1).

From the first-order optimality conditions (3) of problem (2), we construct the following negative gradient flow:

$$\frac{dx(t)}{dt} = -(Ax - \lambda Bx), \quad (5)$$

on the generalized spherical surface,

$$x^T Bx = 1. \quad (6)$$

The system of DAEs (5)-(6) is a special dynamical system which is derived from the equality-constrained optimization problem (2). According to the definition of the differential index of DAEs [11], we can verify that the index of DAEs (5)-(6) is two. Therefore, the solution of DAEs (5)-(6) is not easy to be obtained by the general software package such as bdf15s [7, 11, 12]. Thus, we need to devise a special technique for its steady-state solution.

Differentiating the algebraic constraint $x^T Bx = 1$ along the trajectory $(x(t), \lambda(t))$ of (5) and (6), we obtain

$$\begin{aligned} \frac{d(x^T Bx)}{dt} &= (\nabla_x (x^T Bx))^T \frac{dx}{dt} \\ &= 2x^T B(-Ax + \lambda Bx) \\ &= 2(-x^T BAx + \lambda x^T B^2 x) = 0. \end{aligned} \quad (7)$$

Consequently, we obtain

$$\lambda = \frac{x^T BAx}{x^T B^2 x}. \quad (8)$$

Substituting (8) into (5), we also obtain the following generalized gradient flow:

$$\frac{dx(t)}{dt} = -\left(A - B \frac{x^T BAx}{x^T B^2 x}\right)x, \quad x(0)^T Bx(0) = 1. \quad (9)$$

Conversely, if $x(t)$ is a solution of (9), then $d(x^T Bx)/dt = 0$; that is, $x(t)$ satisfies $x^T Bx = 1$, and consequently $x(t)$ also

satisfies (5)-(6). Therefore, the continuous dynamical system of (5) and (6) is equivalent to the generalized gradient flow (9).

Since the right-hand-side function of (9) is Lipschitz continuous, it has a unique solution $x(t)$ for any initial point $x(0) = x_0$. We can verify that the objective function $f(x) = x^T Ax$ is monotonically decreasing along the trajectory $x(t)$ of (5)-(6). Actually, from (5)-(8), using the Cauchy-Schwartz inequality $|y^T z| \leq \|y\| \|z\|$, we have

$$\begin{aligned} \frac{df(x)}{dt} &= (\nabla_x f(x))^T \frac{dx}{dt} \\ &= 2 \left(-x^T A^2 x + \frac{x^T ABx x^T BAx}{x^T B^2 x} \right) \\ &\leq \frac{2}{x^T B^2 x} (-\|Ax\|^2 \|Bx\|^2 + (Ax)^T (Bx) (Bx)^T (Ax)) \\ &\leq 0. \end{aligned} \quad (10)$$

Furthermore, the solution $x(t)$ of (9) converges to an eigenvector x^* associated with the smallest generalized eigenvalue λ^* of (A, B) , for almost all initial condition $x(0) = x_0$, where x_0 satisfies $\|x_0\| = 1$, except for a set of measure zero, that is, the case of a multiple generalized eigenvalue λ^* [5]. Therefore, by following the trajectory $x(t)$ of (5)-(6), we can compute a global minimum point x^* of problem (2), and consequently obtain the smallest generalized eigenvalue λ^* of (A, B) .

3. A Prediction-Correction Method

In this section, in order to obtain a steady-state solution of DAEs (5)-(6), we construct a prediction-correction method to follow its trajectory. According to the discussion of Section 2, we know that a steady-state solution of DAEs (5)-(6) is a generalized eigenvector associated with the smallest generalized eigenvalue of (A, B) . Therefore, by following the discrete trajectory of DAEs (5)-(6), we can compute an approximate eigenvector associated with the smallest generalized eigenvalue and consequently obtain the smallest generalized eigenvalue.

Note that we mainly consider the steady state of the system of DAEs (5)-(6) and do not care about an accurate solution at its transient-state phase. In order to avoid consuming unnecessary computing time, we adopt the first-order implicit Euler method to follow its trajectory. The time steps of the implicit Euler method are not restricted by the absolute stability property for the linear test equation $dx/dt = -\mu x$, where $\mu > 0$ [7], and consequently the implicit Euler method can take large steps at the steady-state phase so that the iteration sequence $\{x_k\}$ converges rapidly to a stationary point x^* of the system of DAEs (5)-(6).

By applying one implicit Euler iteration to the system of DAEs (5)-(6), we obtain the following iteration formula of the form:

$$x_{k+1} = x_k - \Delta t_k (A - \lambda_{k+1} B) x_{k+1}, \quad (11)$$

$$x_{k+1}^T B x_{k+1} = 1, \quad (12)$$

where Δt_k is the time step. Note that the system of (11)-(12) is nonlinear, and generally, its solution cannot explicitly be obtained. Therefore, we use the alternating projection idea [13, 14] to handle it.

We replace λ_{k+1} with λ_k in (11) to obtain the predicted point x_{k+1}^P as follows:

$$(I + \Delta t_k (A - \lambda_k B)) x_{k+1}^P = x_k. \quad (13)$$

Since the predicted point x_{k+1}^P moves away from the elliptic spherical surface, we project this predicted point x_{k+1}^P onto the unit elliptic spherical surface, so that the iterated point x_{k+1} satisfies the algebraic constraint (6); namely, we find the shortest distance between x_{k+1}^P and the unit elliptic spherical surface. We achieve this aim by solving the following equality-constrained problem:

$$\begin{aligned} \min_{x \in \mathbb{R}^n} & \|x - x_{k+1}^P\|, \\ \text{s.t. } & x^T B x = 1. \end{aligned} \quad (14)$$

Since the optimal solution of the previously problem is not apparently obtained, we turn to achieve its suboptimal solution. Since matrix B is positive, it can be decomposed as $B = L^T L$. Let $y = Lx$. Then, problem (14) is equivalent to the following problem:

$$\begin{aligned} \min_{y \in \mathbb{R}^n} & \|L^{-1}(y - Lx_{k+1}^P)\|, \\ \text{s.t. } & \|y\| = 1. \end{aligned} \quad (15)$$

Since $\|L^{-1}(y - Lx_{k+1}^P)\| \leq \|L^{-1}\| \|y - Lx_{k+1}^P\|$, we obtain the suboptimal solution by solving the following problem:

$$\begin{aligned} \min_{y \in \mathbb{R}^n} & \|y - Lx_{k+1}^P\|, \\ \text{s.t. } & \|y\| = 1. \end{aligned} \quad (16)$$

From the shortest distance between a point and a unit spherical surface being the intersection point of the straight line through the center of that circle and the point and that unit spherical surface, we obtain the previous minimum point as $y_{k+1} = Lx_{k+1}^T / \|Lx_{k+1}^P\|$. Then, the suboptimal solution point of problem (14) is obtained as

$$x_{k+1} = L^{-1} y_{k+1} = \frac{x_{k+1}^P}{\|Lx_{k+1}^P\|}. \quad (17)$$

Now, we use the correction point x_{k+1} to update λ_{k+1} , so that the steady-state equation $Ax - \lambda Bx = 0$ is satisfied as

possible. Namely, we find the minimum point of the following problem:

$$\min_{\lambda \in \mathbb{R}^n} \|Ax_{k+1} - \lambda Bx_{k+1}\|. \quad (18)$$

Since matrix B is positive, it can be decomposed as $B = L^T L$. Let $z_{k+1} = Lx_{k+1}$. Then, the previous minimum problem is equivalent to the following problem:

$$\min_{\lambda \in \mathbb{R}^n} \|L^T (L^{-T} Ax_{k+1} - \lambda Lx_{k+1})\|. \quad (19)$$

Using the property $\|L^T (L^{-T} Ax_{k+1} - \lambda Lx_{k+1})\| \leq \|L^T\| \|L^{-T} Ax_{k+1} - \lambda Lx_{k+1}\|$, we obtain the suboptimal solution of problem (18) by solving the following problem:

$$\min \|L^{-T} Ax_{k+1} - \lambda Lx_{k+1}\|. \quad (20)$$

It is not difficult to obtain the minimum solution of the previous problem as

$$\lambda_{k+1} = \frac{x_{k+1}^T Ax_{k+1}}{x_{k+1}^T Bx_{k+1}}, \quad (21)$$

which is the suboptimal solution of problem (18).

Another issue is how to choose the time step Δt_k at every iteration. We adopt an analogous trust-region technique to adaptively adjust the time step Δt_k . Our intuition is that the time step Δt_k can be enlarged when the predicted point x_{k+1}^P is also near the elliptic spherical surface $x^T Bx = 1$; otherwise, the time step Δt_k is reduced. In order to measure the distance between x_{k+1}^P and the unit elliptic spherical surface, we construct the following approximate model:

$$\rho_k = \left| 1 - \left((x_{k+1}^P)^T Bx_{k+1}^P \right)^{1/2} \right|. \quad (22)$$

Then,

$$\Delta t_{k+1} = \begin{cases} \gamma_1 \Delta t_k, & \text{if } \rho_k < \eta_1, \\ \Delta t_k, & \text{if } \eta_1 \leq \rho_k \leq \eta_2, \\ \gamma_2 \Delta t_k, & \text{if } \rho_k \geq \eta_2, \end{cases} \quad (23)$$

where constants η_1, η_2, γ_1 , and γ_2 satisfy

$$0 < \eta_1 < \eta_2 < 1, \quad 0 < \gamma_2 < 1 < \gamma_1. \quad (24)$$

According to the previous discussion, we give the following discrete dynamical method for the smallest generalized eigenvalue of (A, B) .

Algorithm 1. Prediction-correction method for the smallest generalized eigenvalue.

Step 1. Initialize the parameters. Specify a tolerated error TOL and an initial point x_0 to satisfy

$$x_0^T Bx_0 = 1. \quad (25)$$

Compute $\lambda_0 = x_0^T Ax_0 / x_0^T Bx_0$ and the residual $r_0 = \|Ax_0 - \lambda_0 Bx_0\|$.

Step 2. Repeat for $k = 0, 1, 2, \dots$ until $r_k = \|Ax_k - \lambda_k Bx_k\| \leq \text{TOL}$:

- (a) solve (13) to obtain the predicted point x_{k+1}^P ;
- (b) evaluate (17) to obtain the corrected point x_{k+1} ;
- (c) compute (21) to update the Lagrange multiplier λ_{k+1} ;
- (d) compute the residual

$$r_{k+1} = \|Ax_{k+1} - \lambda_{k+1}Bx_{k+1}\|; \quad (26)$$

- (e) update the time step Δt_{k+1} according to the time-stepping scheme (22)-(23);
- (f) accept the trial vector. If $\rho_k < \eta_2$, let $x_k = x_{k+1}$, $\lambda_k = \lambda_{k+1}$ and $r_k = r_{k+1}$;
- (g) try again starting at (a) with $k \leftarrow k + 1$.

4. Local Convergence Analysis

The sequence (x_k, λ_k) generated by Algorithm 1 follows the continuous trajectory (5)-(6). Adopting the similar estimation technique in [15, 16], we obtain that the local truncation error of x_k is $O(\Delta t_k)$. According to the standard analysis of numerical ordinary differential equations [7, 11], we know that x_k is close to $x(t_k)$ when Δt_k is small enough in the finite time interval $[0, T]$. Therefore, we only need to estimate the local convergence rate of x_k in the steady-state phase.

For the convenience of analysis, we decompose matrix B as $B = L^T L$ and denote $C = L^{-T} A L^{-1}$. Then, the smallest generalized eigenvalue λ^* of (A, B) and associated with the eigenvector x^* is equivalent to the smallest eigenvalue of symmetric matrix C and associated with the eigenvector $y^* = Lx^*$, respectively. Therefore, we only need to consider the convergence property of (y_k, λ_k) , where $y_k = Lx_k$. x_k is generated by Algorithm 1.

We denote the error angle between y_k and y^* by $\phi_k = \angle(y_k, y^*)$. Then, the current iteration y_k can be decomposed as

$$y_k = y^* \cos \phi_k + u_k \sin \phi_k, \quad (27)$$

where $u_k^T y^* = 0$ and $\|u_k\| = \|y^*\| = 1$. From (27), we obtain

$$\begin{aligned} \lambda_{\min} - \lambda_k &= \lambda_{\min} - y_k^T C y_k \\ &= \lambda_{\min} - (y^* \cos \phi_k + u_k \sin \phi_k)^T \\ &\quad \times C (y^* \cos \phi_k + u_k \sin \phi_k) \\ &= \lambda_{\min} - \lambda_{\min} \cos^2 \phi_k - (u_k^T C u_k) \sin^2 \phi_k \\ &= (\lambda_{\min} - (u_k^T C u_k)) \sin^2 \phi_k. \end{aligned} \quad (28)$$

According to the previous discussion, we give the following local convergence property for Algorithm 1.

Theorem 2. Assume that the sequence (x_k, λ_k) is generated by Algorithm 1. Then, the sequence of error angles ϕ_k tends to zero superlinearly.

Proof. From (21) and $Cy^* = \lambda^* y^*$, we have

$$\begin{aligned} \lambda_k - \lambda^* &= y_k^T (C - \lambda^* I) y_k \\ &= (y_k - y^*)^T (C - \lambda^* I) (y_k - y^*). \end{aligned} \quad (29)$$

It gives

$$|\lambda_k - \lambda^*| \leq |\lambda_{\max} - \lambda^*| \|y^k - y^*\|^2. \quad (30)$$

Thus, we choose a small enough positive $\varepsilon_1 > 0$, such as $\varepsilon_1 = 3/4|\lambda^* - \mu_2|$, and a large enough k to satisfy

$$|\lambda_k - \mu_2| > \varepsilon_1, \quad |\lambda_{\max} - \lambda^*| \|y^k - y^*\|^2 < \frac{1}{2}\varepsilon_1. \quad (31)$$

Then, combining inequality (30), we have

$$|\lambda_k - \lambda^*| \leq \frac{1}{2}\varepsilon_1. \quad (32)$$

Consequently, we obtain

$$\begin{aligned} q_k(\Delta t_k) &:= \frac{1/\Delta t_k + |\lambda^* - \lambda_k|}{1/\Delta t_k + |\mu_2 - \lambda_k|} \\ &\leq \frac{1/\Delta t_k + 1/2\varepsilon_1}{1/\Delta t_k + \varepsilon_1} \\ &\leq \frac{1/\Delta t_{\min} + 1/2\varepsilon_1}{1/\Delta t_{\min} + \varepsilon_1} < 1. \end{aligned} \quad (33)$$

We can verify that there exists a positive constant ε_t such that all the time steps Δt_k are bounded below by $\Delta t_{\min}$; that is, $\Delta t_k \geq \Delta t_{\min}$. Actually, from (13), we know that $\|x_{k+1}^P\|$ will be close to $\|x_k\|$, when Δt_k is small enough. Consequently, for small enough Δt_k , we have

$$\begin{aligned} |x_{k+1}^P B x_{k+1} - 1| &= |x_{k+1}^P B x_{k+1} - x_k B x_k| \\ &= |(x_{k+1}^P - x_k)^T B (x_{k+1}^P - x_k)| < \eta_1. \end{aligned} \quad (34)$$

According to the time-stepping strategy (23), Δt_{k+1} will be enlarged. Therefore, Δt_k are bounded below by a positive number $\Delta t_{\min}$.

On the other hand, from (13) and (27), we obtain

$$\begin{aligned} y_{k+1}^P &= (I + \Delta t_k (C - \lambda_k I))^{-1} y_k \\ &= (I + \Delta t_k (C - \lambda_k I))^{-1} \\ &\quad \times (y^* \cos \phi_k + u_k \sin \phi_k) \\ &= \frac{y^* \cos \phi_k}{(1 + \Delta t_k (\lambda_{\min} - \lambda_k))} \\ &\quad + (I + \Delta t_k (C - \lambda_k I))^{-1} u_k \sin \phi_k \\ &= \frac{y^* \cos \phi_k}{(1 + \Delta t_k (\lambda_{\min} - \lambda_k))} \\ &\quad + u_{k+1} \sin \phi_k \|(I + \Delta t_k (C - \lambda_k I))^{-1} u_k\|, \end{aligned} \quad (35)$$

where $u_{k+1} = (I + \Delta t_k (C - \lambda_k I))^{-1} u_k / \|(I + \Delta t_k (C - \lambda_k I))^{-1} u_k\|$ and $u_{k+1}^T y^* = 0$. Noticing $y_{k+1} = y_{k+1}^P / \|y_{k+1}^P\|$ and $y_{k+1} = y^* \cos \phi_{k+1} + u_{k+1} \sin \phi_{k+1}$, from (35), we obtain

$$\tan \phi_{k+1} = \tan \phi_k \|(I + \Delta t_k (C - \lambda_k I))^{-1} u_k\| \times (1 + \Delta t_k (\lambda_{\min} - \lambda_k)). \quad (36)$$

Since u_k is orthogonal to y^* and $\|u_k\| = 1$, u_k can be decomposed as $u_k = \alpha_2 z_2 + \dots + \alpha_n z_n$, where $\alpha_2^2 + \alpha_3^2 + \dots + \alpha_n^2 = 1$. Let μ_i ($i = 1, 2, \dots, n$) be the eigenvalues of $C = L^{-T} A L^{-1}$ in ascending order. Thus, from the spectral decomposition of C , for large enough k , we obtain

$$\begin{aligned} & \|(I + \Delta t_k (C - \lambda_k I))^{-1} u_k\|^2 \\ &= \left\| \sum_{i=2}^n (1 + \Delta t_k (\mu_i - \lambda_k))^{-1} \alpha_i z_i \right\|^2 \\ &= \sum_{i=2}^n (1 + \Delta t_k (\mu_i - \lambda_k))^{-2} \alpha_i^2 \\ &\leq \sum_{i=2}^n (1 + \Delta t_k (\mu_2 - \lambda_k))^{-2} \alpha_i^2 \\ &= (1 + \Delta t_k (\mu_2 - \lambda_k))^{-2}. \end{aligned} \quad (37)$$

It gives

$$\|(I + \Delta t_k (C - \lambda_k I))^{-1} u_k\| \leq \frac{1}{(1 + \Delta t_k (\mu_2 - \lambda_k))}. \quad (38)$$

From (36) and (38), for large enough k , we have

$$|\tan \phi_{k+1}| \leq |\tan \phi_k| \frac{(1/\Delta t_k + |\lambda^* - \lambda_k|)}{(1/\Delta t_k + \mu_2 - \lambda_k)}. \quad (39)$$

Combining (33) and (39), we know that ϕ_k converges linearly to zero; namely, y_k converges linearly to y^* , when we choose the initial k such that (y_k, λ_k) is close enough (y^*, λ^*) .

Since (y_k, λ_k) converges linearly to (y^*, λ^*) , according to the time-stepping strategy (23), we obtain that the time step Δt_k will tend to infinity. Consequently, from inequality (39), we know that ϕ_k superlinearly converges to 0. $\square$

Remark 3. From (28) and inequality (39), we have

$$\begin{aligned} & |\tan \phi_{k+1}| \\ &\leq |\tan \phi_k| \frac{(1/\Delta t_k + |\lambda_{\min} - \lambda_k|)}{(1/\Delta t_k + \mu_2 - \lambda_k)} \\ &= |\tan \phi_k| \frac{(1/\Delta t_k + |(\lambda_{\min} - u_k^T A u_k) \sin^2 \phi_k|)}{(1/\Delta t_k + \mu_2 - \lambda_k)}. \end{aligned} \quad (40)$$

Consequently, the error angles ϕ_k tend to zero cubically, if we adopt a suitable time-stepping strategy such as $1/\Delta t_k \approx \sin^2 \phi_k$ for large enough k .

Remark 4. The convergence rate of the Rayleigh quotient iteration is cubic; however, its iterate point sequence $\{x_k\}$ is not guaranteed to converge to the smallest generalized eigenvalue of (A, B) [17]. The convergence rate of Algorithm 1 is less than the convergence rate of the Rayleigh quotient iteration, but the iterate point sequence $\{x_k\}$ of Algorithm 1 follows the trajectory of the special dynamical system of DAEs (5)-(6), and consequently it converges to a stationary point x^* of the system of DAEs (5)-(6), that is, one of generalized eigenvectors associated with the smallest generalized eigenvalue λ^* of (A, B) .

5. Numerical Experiments

We give some numerical experiments for Algorithm 1 (which is denoted by the PCM method), in comparison with the recent continuous projected method by Gao et al. (which is denoted by the GGL method [4]) the restarted Arnoldi method (the EIGS method [18]), and the Jacobi-Davidson method (JDQZ [19, 20]). For Algorithm 1, we pick $\eta_1 = 0.25$, $\eta_2 = 0.75$, $\gamma_1 = 2$, and $\gamma_2 = 0.5$ and compute an initial time-step length Δt_0 as follows:

$$\Delta t_0 = \min \left\{ 0.01, \frac{1}{\|Ax_0 - \lambda_0 Bx_0\|_2} \right\}. \quad (41)$$

For the GGL method, we use the solver ODE45 [12] for the continuous projected dynamical method and set RelTol = 10^{-6} and AbsTol = 10^{-9} , which are suggested in [4]. All of our tests were run in Matlab 2009a environment on a Lenovo Thinkpad laptop X200 with 2.4 GHz processor. The compared methods for the test problems are terminated when the condition

$$\|Ax_k - \lambda_k Bx_k\|_{\infty} \leq 10^{-6} \quad (42)$$

is satisfied. The descriptions of test problems and the numerical results are presented by the following.

Example 5 (see [4, 21]). This test problem has four generalized eigenvalues. The first three generalized eigenvalues are 0, 0, and 0, and the other is 2. The stiffness and mass matrices are given as follows:

$$\begin{aligned} A &= \begin{bmatrix} 1 & 0 & -1 & 0 \\ 0 & 0 & 0 & 0 \\ -1 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}, \\ B &= \begin{bmatrix} 2 & 0 & 1 & 0 \\ 0 & 2 & 0 & 1 \\ 1 & 0 & 2 & 0 \\ 0 & 1 & 0 & 2 \end{bmatrix}. \end{aligned} \quad (43)$$

It is not difficult to verify that matrix B is positive definite. We choose an initial point $x_0 = [0.2, 0.6, -0.8, 0.6]^T$.

TABLE 1: Comparison with different methods.

Examples	PCM		GGL		EIGS	JDQZ
	λ_k	Iter (CPU)	λ_k	Iter (CPU)	CPU	CPU
Example 5	$1.0e-13$	12 (0.021)	$4.5e-11$	77 (0.178)	FAIL	FAIL
Example 6	0.01337	18 (0.004)	0.01344	3389 (0.36)	0.01	0.49
Example 7	0.4998	49 (2.556)	0.5	33 (6.643)	0.24	14.17
Example 8	$1.1e-5$	28 (0.024)	0.0122	514 (169.3)	0.02	0.686

Example 6 (see [4, 21]). The stiffness and mass matrices are given as follows:

$$A = \begin{bmatrix} 11k_1 + k_2 & -k_2 & & & \\ -k_2 & k_2 + k_3 & \ddots & & \\ & \ddots & \ddots & \ddots & \\ & & \ddots & k_{n-1} + k_n & -k_n \\ & & & -k_n & 11k_n + k_{n+1} \end{bmatrix}, \quad (44)$$

and $B = \text{diag}(m_1, m_2, \dots, m_n)$ with $n = 20$, $k_i = 4 + i$, and $m_i = 35 - i$ for $i = 1, 2, \dots, 20$.

Example 7 (see [22]). This test problem is from fluid flow generalized eigenvalues (see the Bcsstruc1 set in [22]).

Consider the following

$$Kx = \lambda Mx. \quad (45)$$

Here, the mass matrix M (bcsstm13.mtx) is a real symmetric positive semidefinite matrix; and the stiffness matrix K (bcsstk13.mtx) is a real positive definite matrix. Therefore, its smallest generalized eigenvalue is zero. In order to test the effect of algorithms, we apply a shift to M as follows:

$$B = M + 2K. \quad (46)$$

Then, the smallest generalized eigenvalue of (K, B) is $1/2$.

Example 8. In order to test the performance of these two methods for large-scale problems, we construct a large-sparse matrix A as follows:

- (1) let $A_1 = \text{sparse}(\text{diag}(\text{ones}(n, 1)))$;
- (2) let $A_2 = \text{sparse}(\text{diag}(\text{ones}(n-1, 1), 1))$;
- (3) let $A_3 = \text{sparse}(\text{diag}(\text{ones}(n-1, 1), -1))$;
- (4) let $A = 2A_1 + A_2 + A_3$;
- (5) let $B = 4A_1 + A_2 + A_3$.

Here, `sparse.m`, `diag.m`, and `ones.m` are the Matlab functions, and n is the dimension of A . In our numerical experiments, we set $n = 1000$ for this test problem.

Numerical results for these four test problems are reported in Table 1. Iter and CPU designate the number of iterations and the computed time (given in seconds), respectively. From the computed results for Examples 5 and 8 in Table 1, we see that the proposed method (the PCM method) manages to find a smaller minimum eigenvalue than

FIGURE 1: Numerical results of Example 5 with PCM and GGL methods.

FIGURE 2: Numerical results of Example 6 with PCM and GGL methods.

the compared method (the GGL method). Furthermore, the computed time of the PCM method is less than the GGL method and the JDQZ method for these test problems. For Example 5, the EIGS method fails since it gives the message: “(A-sigma*B) is singular. The shift is an eigenvalue. Try to use some other shift please,” when we execute it.

In order to record the convergence history, we draw the iteration trajectory of the smallest eigenvalue computed by the PCM method and by the GGL method for every test problem in Figures 1, 2, 3, and 4. From those figures, we find

FIGURE 3: Numerical results of Example 7 with PCM and GGL methods.

FIGURE 4: Numerical results of Example 8 with PCM and GGL methods.

that Algorithm 1 (the PCM method) achieves the steady state of the dynamical system faster than the GGL method.

In order to test the sensitivity of Algorithm 1, we compute the test problems with Algorithm 1 for different parameters γ_1 , γ_2 , η_1 , and η_2 . The robustness of Algorithm 1 is mainly determined by the parameters η_1 and η_2 and the parameters η_1 and η_2 affect its efficiency. Thus, we fix parameters $\gamma_1 = 2$ and $\gamma_2 = 1/2$. We choose four groups of parameters η_1 and η_2 as following:

- (I) $\eta_1 = 0.25$, $\eta_2 = 0.75$;
- (II) $\eta_1 = 0.1$, $\eta_2 = 0.9$;

TABLE 2: Numerical results for different parameters of Algorithm 1.

Examples	(I) Iter (CPU)	(II) Iter (CPU)	(III) Iter (CPU)	(IV) Iter (CPU)
Example 5	12	12	12	12
Example 6	19	19	19	17
Example 7	49	49	50	45
Example 8	26	31	22	22

(III) $\eta_1 = 0.3$, $\eta_2 = 0.7$;

(IV) $\eta_1 = 0.4$, $\eta_2 = 0.8$.

The numerical results are reported in Table 2. From Table 2, we find that Algorithm 1 is not sensitive for different parameters η_1 around 0.25 and η_2 around 0.75. Thus, we set the default parameters $\eta_1 = 0.25$ and $\eta_2 = 0.75$ in Algorithm 1.

6. Conclusions

This paper discusses the connection between the smallest generalized eigenvalue problem and the continuous dynamical system of DAEs. The trajectory of this special dynamical system is followed by a new prediction-correction method (Algorithm 1), which is derived from the implicit Euler formula and an analogous trust-region technique. Consequently, an equilibrium point x^* of this continuous dynamical system is obtained. This equilibrium point x^* is also a generalized eigenvector associated with the smallest generalized eigenvalue. The local superlinear property for the new prediction-correction method is presented. Numerical experiments indicate that Algorithm 1 is promising for the smallest generalized eigenvalue problem. Another interesting issue is whether or not the second-order, pseudo-transient method [23] obtains the superior numerical property for this special dynamical system of DAEs (5)-(6). We would like to consider this issue in our future works.
