We will study the uniqueness problems of meromorphic functions of differential polynomials sharing fixed points. Our results improve or generalize some previous results on meromorphic functions sharing fixed points.

1. Introduction and Main Results

Let $\mathbb{C}$ denote the complex plane and let $f(z)$ be a nonconstant meromorphic function on $\mathbb{C}$. We assume the reader is familiar with the standard notion used in the Nevanlinna value distribution theory such as $T(r, f)$, $m(r, f)$, and $N(r, f)$ (see, e.g., [1–3]), and $S(r, f)$ denotes any quantity that satisfies the condition $S(r, f) = o(T(r, f))$ as $r \rightarrow \infty$ outside of a possible exceptional set of finite linear measure.

Let $f(z)$ and $g(z)$ be two nonconstant meromorphic functions. Let $a \in \mathbb{C} \cup \{\infty\}$; we say that $f(z)$, $g(z)$ share a CM (counting multiplicities) if $f(z) - a$, $g(z) - a$ have the same zeros with the same multiplicities and we say that $f(z)$, $g(z)$ share a IM (ignoring multiplicities) if we do not consider the multiplicities. We denote by $\overline{N}_L(r, 1/(f - a))$ ($\overline{N}_L(r, 1/(g - a))$) the counting function of those a -points of f whose multiplicities are greater (less) than the multiplicities of the corresponding a -points of g , where each a -point is counted only once. $N_k(r, 1/(f - a))$ denotes the truncated counting function bounded by k .

We say that a finite value z_0 is called a fixed point of f if $f(z_0) = z_0$ or z_0 is a zero of $f(z) - z$.

The following theorem in the value distribution theory is well-known [4, 5].

Theorem A. Let $f(z)$ be a transcendental meromorphic function and $n \geq 1$ a positive integer. Then $f^n f' = 1$ has infinitely many solutions.

Related to Theorem A, Fang [6] proved that a meromorphic function $f^n f'$ has infinitely many fixed points when f is transcendental and n is a positive integer. Then Fang and Qiu [7] obtained the following uniqueness theorem.

Theorem B. Let f and g be two nonconstant meromorphic (entire) functions and $n \geq 11$ (≥ 6) a positive integer. If $f^n(z)f'(z)$ and $g^n(z)g'(z)$ share z CM, then either $f(z) = c_1 e^{cz^2}$, $g(z) = c_2 e^{-cz^2}$, where c_1, c_2 , and c are three constants satisfying $4(c_1 c_2)^{n+1} c^2 = -1$, or $f(z) \equiv tg(z)$ for a constant t such that $t^{n+1} = 1$.

For more related results, see [8, 9]. Recently, Cao and Zhang [10] replaced f' with $f^{(k)}$ and obtained the following.

Theorem C. Let $f(z)$ and $g(z)$ be two transcendental meromorphic functions, whose zeros are of multiplicities at least k , where k is a positive integer; let $n > \max\{2k - 1, k + 4/k + 4\}$ be a positive integer. If $f^n f^{(k)}$ and $g^n g^{(k)}$ share z CM, and f and g share ∞ IM, then one of the following two conclusions holds:

- (1) $f^n f^{(k)} = g^n g^{(k)}$;
- (2) $f = c_1 e^{cz^2}$, $g = c_2 e^{-cz^2}$, where c_1, c_2 , and c are constants such that $4(c_1 c_2)^{n+1} c^2 = -1$.

Regarding Theorem C, it is natural to ask the following.

Problem 1. Does Theorem C still hold without the “transcendental” condition?

Problem 2. Does Theorem C still hold without the “multiplicity of zeros of f and g ” condition?

Problem 3. Can the lower bound of n be reduced in Theorem C?

We consider Problems 1–3 and give affirmative answers to them, and we get the following.

Theorem 1. Let $f(z)$ and $g(z)$ be two nonconstant meromorphic functions and n, k two positive integers with $n > k + 8$. If $f^n f^{(k)}$ and $g^n g^{(k)}$ share z CM, and f and g share ∞ IM, then one of the following two conclusions holds:

- (1) $f^n f^{(k)} = g^n g^{(k)}$;
- (2) $f = c_1 e^{cz^2}$, $g = c_2 e^{-cz^2}$, where c_1, c_2 , and c are constants such that $4(c_1 c_2)^{n+1} c^2 = -1$.

One may ask whether the condition “ $n > k + 8$ ” can be further reduced. We have proved the following.

Theorem 2. Let $f(z)$ and $g(z)$ be two nonconstant meromorphic functions and n, k two positive integers with $n > k + 7$. If $f^n f^{(k)}$ and $g^n g^{(k)}$ share z CM, and f and g share ∞ IM, then one of the following two conclusions holds:

- (1) $f^n f^{(k)} = g^n g^{(k)}$, possibly except for at most one exceptional case, namely,

$$\begin{aligned} k &= 1, \quad n = 9, \\ f &= a \frac{(z - a_1)(z - a_2)(z - a_3)}{(z - d_1)^2(z - d_2)}, \\ g &= b \frac{(z - b_1)(z - b_2)(z - b_3)}{(z - d_1)(z - d_2)^2}, \end{aligned} \quad (1)$$

where a_j, b_j ($j = 1, 2, 3$), d_1, d_2 are 8 distinct constants and a, b are two nonzero constants;

- (2) $f = c_1 e^{cz^2}$, $g = c_2 e^{-cz^2}$, where c_1, c_2 , and c are constants such that $4(c_1 c_2)^{n+1} c^2 = -1$.

If f and g are two transcendental meromorphic functions, the lower bound of n in Theorem 2 can be further reduced. We have the following.

Theorem 3. Let $f(z)$ and $g(z)$ be two transcendental meromorphic functions and n, k two positive integers with $n > k + 6$. If $f^n f^{(k)}$ and $g^n g^{(k)}$ share z CM, and f and g share ∞ IM, then one of the following two conclusions holds:

- (1) $f^n f^{(k)} = g^n g^{(k)}$;
- (2) $f = c_1 e^{cz^2}$, $g = c_2 e^{-cz^2}$, where c_1, c_2 , and c are constants such that $4(c_1 c_2)^{n+1} c^2 = -1$.

2. Preliminary Lemmas

Let

$$H = \left(\frac{F''}{F'} - \frac{2F'}{F-1} \right) - \left(\frac{G''}{G'} - \frac{2G'}{G-1} \right), \quad (2)$$

$$V = \left(\frac{F'}{F-1} - \frac{F'}{F} \right) - \left(\frac{G'}{G-1} - \frac{G'}{G} \right), \quad (3)$$

where F and G are meromorphic functions.

Lemma 4 (see [11]). Let $f(z)$ be a nonconstant meromorphic function and let $a_0(z), a_1(z), \dots, a_n(z)$ ($\neq 0$) be small functions with respect to f . Then

$$T(r, a_n f^n + a_{n-1} f^{n-1} + \dots + a_0) = nT(r, f) + S(r, f). \quad (4)$$

Lemma 5 (see [2]). Let $f(z)$ be a nonconstant meromorphic function, and let k be a positive integer. Suppose that $f^{(k)} \neq 0$; then

$$N\left(r, \frac{1}{f^{(k)}}\right) \leq N\left(r, \frac{1}{f}\right) + k\bar{N}(r, f) + S(r, f). \quad (5)$$

By using the similar method to Yang and Hua [12, Lemma 3], we can prove the following lemma.

Lemma 6. Let F, G , and H be defined as in (2). If F and G share 1 CM and ∞ IM, and $H \neq 0$, then $F \equiv G$, and

$$\begin{aligned} T(r, F) &\leq N_2\left(r, \frac{1}{F}\right) + N_2\left(r, \frac{1}{G}\right) + 2\bar{N}(r, F) \\ &\quad + \bar{N}_L(r, F) + \bar{N}_L(r, G) + S(r, F) + S(r, G), \end{aligned} \quad (6)$$

the same inequality holding for $T(r, G)$.

Lemma 7 (see [13]). Let F, G , and V be defined as in (3). If F and G share ∞ IM, and $V \equiv 0$, then $F \equiv G$.

Lemma 8. Let f, g be two nonconstant meromorphic functions, V defined as in (3), where $F = f^n f^{(k)}/z$, $G = g^n g^{(k)}/z$, and $n > 0$, $k > 0$, and $m \geq 0$ three integers. If $V \neq 0$, F and G share 1 CM, and f and g share ∞ IM, then

$$\begin{aligned} (n-k)\bar{N}(r, f) &= (n-k)\bar{N}(r, g) \\ &\leq 2\left(N\left(r, \frac{1}{f}\right) + N\left(r, \frac{1}{g}\right)\right) \\ &\quad + S(r, f) + S(r, g). \end{aligned} \quad (7)$$

Proof. Note that $V \neq 0$, f and g share ∞ IM, suppose that $z_0 \neq 0$ is a pole of $f(g)$ with multiplicity $p(q)$, then z_0 is a pole of $F(G)$ with multiplicity $np + p + k$ ($nq + q + k$). Thus z_0 is a zero of $F'(F-1) - F'/F$ with multiplicity $np + p + k - 1$ ($\geq n + k$), and a zero of $G'(G-1) - G'/G$ with multiplicity $np + p + k - 1$ ($\geq n + k$). Hence z_0 is a zero of V with multiplicity at least $n + k$. Suppose that $z_1 = 0$ is a pole of $f(g)$ with multiplicity $r(s)$, by

the similar discussion as above, we get that $z_1 = 0$ is a zero of V with multiplicity at least $n + k + 1$. So we have

$$(n + k) \overline{N}(r, f) = (n + k) \overline{N}(r, g) \leq N\left(r, \frac{1}{V}\right). \quad (8)$$

By the logarithmic derivative lemma, we have $m(r, V) = S(r, f) + S(r, g)$. Note that F and G share 1 CM, so we have

$$\begin{aligned} N\left(r, \frac{1}{V}\right) &\leq T(r, V) = m(r, V) + N(r, V) \\ &\leq \overline{N}\left(r, \frac{1}{F}\right) + \overline{N}\left(r, \frac{1}{G}\right) + S(r, f) + S(r, g). \end{aligned} \quad (9)$$

Obviously,

$$\begin{aligned} \overline{N}\left(r, \frac{1}{F}\right) &\leq 2N\left(r, \frac{1}{f}\right) + k\overline{N}(r, f) + S(r, f), \\ \overline{N}\left(r, \frac{1}{G}\right) &\leq 2N\left(r, \frac{1}{g}\right) + k\overline{N}(r, g) + S(r, g). \end{aligned} \quad (10)$$

From (8)–(10) we get (7). This proves Lemma 8. $\square$

Lemma 9 (see [1, Theorem 3.10]). *Suppose that f is a nonconstant meromorphic function; $k \geq 2$ is an integer. If*

$$N(r, f) + N\left(r, \frac{1}{f}\right) + N\left(r, \frac{1}{f^{(k)}}\right) = S\left(r, \frac{f'}{f}\right), \quad (11)$$

then $f = e^{az+b}$, where $a \neq 0$, b are constants.

Lemma 10. *Let f, g be two nonconstant meromorphic functions and $n (\geq 2)$, k two positive integers. If $f^n f^{(k)} g^n g^{(k)} = z^2$, and f and g share ∞ IM, then $f = c_1 e^{cz^2}$, $g = c_2 e^{-cz^2}$, where c_1, c_2 , and c are constants such that $4(c_1 c_2)^{n+1} c^2 = -1$.*

Proof. Since f and g share ∞ IM, from

$$f^n f^{(k)} g^n g^{(k)} = z^2 \quad (12)$$

we get that both f and g are entire functions.

The case $k = 1$ has been proved by Fang and Qiu [7, Proposition 2]; here we only need to consider the case $k \geq 2$.

Let $F_1 = f^n f^{(k)}$, $G_1 = g^n g^{(k)}$. Then we have

$$\begin{aligned} nT(r, f) &= T(r, f^n) \\ &= T\left(r, \frac{F_1}{f^{(k)}}\right) \\ &\leq T(r, F_1) + T(r, f^{(k)}) + S(r, f) \\ &\leq T(r, F_1) + T(r, f) + S(r, f). \end{aligned} \quad (13)$$

We obtain from (13) that

$$T(r, f) = O(T(r, F_1)). \quad (14)$$

Note that

$$\begin{aligned} T(r, F_1) &= T(r, f^n f^{(k)}) \\ &\leq nT(r, f) + T(r, f^{(k)}) + S(r, f) \\ &\leq (n + 1)T(r, f) + S(r, f). \end{aligned} \quad (15)$$

We obtain from (15) that

$$T(r, F) = O(T(r, f)). \quad (16)$$

Thus from (14) and (16) we have $\sigma(f) = \sigma(F)$. Similarly we have $\sigma(g) = \sigma(G)$. It follows from (12) that $\sigma(F) = \sigma(G)$; we get $\sigma(f) = \sigma(g)$.

Suppose that f has a zero z_0 , say multiplicity p ; then z_0 is a zero of f^n with multiplicity $np \geq 2$. In view of (12), we get $n = 2$ and $z_0 = 0$. Moreover, g has no zero. Therefore,

$$f(z) = ze^{\alpha_1(z)}, \quad g(z) = e^{\beta_1(z)}, \quad (17)$$

where $\alpha_1(z)$, $\beta_1(z)$ are nonconstant entire functions. We deduce that either both α and β are transcendental functions or both α_1 and β_1 are polynomials. From (17) we have

$$T\left(r, \frac{f'}{f}\right) = T\left(r, \alpha'_1 + \frac{1}{z}\right). \quad (18)$$

Moreover, we have

$$N\left(r, \frac{1}{f^{(k)}}\right) = 0. \quad (19)$$

Thus we get

$$N(r, f) + N\left(r, \frac{1}{f}\right) + N\left(r, \frac{1}{f^{(k)}}\right) = O(\log r). \quad (20)$$

If $k \geq 2$, suppose that α is a transcendental entire function. We deduce from Lemma 9 and (17) and (18) that α_1 is a polynomial, which is a contradiction. Thus α_1 is a polynomial and so is β_1 .

So from (12) we get

$$\begin{aligned} &\left[z \left((\alpha'_1)^k + P_{k-1}(\alpha'_1) \right) + \bar{P}_{k-1}(\alpha'_1) \right] \\ &\times \left[(\beta'_1)^k + Q_{k-1}(\beta'_1) \right] e^{3(\alpha_1(z) + \beta_1(z))} = 1, \end{aligned} \quad (21)$$

where $P_{k-1}(\alpha'_1)$, $\bar{P}_{k-1}(\alpha'_1)$, and $Q_{k-1}(\beta'_1)$ are differential polynomials in α'_1 and β'_1 of degree at most $k - 1$, respectively.

Since $\alpha'_1 \not\equiv 0$, $\beta'_1 \not\equiv 0$, by (21) we immediately get a contradiction.

Thus f has no zero; similarly, we get that g has no zero. So we have

$$f(z) = e^{\alpha(z)}, \quad g(z) = e^{\beta(z)}, \quad (22)$$

where $\alpha(z)$, $\beta(z)$ are nonconstant entire functions.

With similar discussion as above, we get that $\alpha + \beta \equiv C$, where C is a constant and α and β are both polynomials.

We deduce from (22) that

$$\begin{aligned} f^{(k)} &= \left[(\alpha')^k + P_{k-1}(\alpha') \right] e^\alpha, \\ g^{(k)} &= \left[(\beta')^k + Q_{k-1}(\beta') \right] e^\beta, \end{aligned} \quad (23)$$

where $P_{k-1}(\alpha')$ and $Q_{k-1}(\beta')$ are differential polynomials in α' and β' of degree at most $k-1$, respectively. Thus from (12) we obtain

$$(-1)^k (\alpha')^{2k} = z^2 + \bar{P}_{2k-1}(\alpha'). \quad (24)$$

If $k \geq 2$, since α' is not a constant, $\deg(\alpha') \geq 1$, by (24) we immediately get a contradiction.

This proves Lemma 10. $\square$

3. Proof of Theorems 1–3

Since the proof of Theorems 1 and 3 is quite similar to the proof of Theorem 2, here we only need to prove Theorem 2.

Let $F = f^n f^{(k)}/z$, $G = g^n g^{(k)}/z$, $F_1 = f^n f^{(k)}$, and $G_1 = g^n g^{(k)}$. Then F and G share 1 CM and ∞ IM.

Suppose that $H \neq 0$; then $F \neq G$, and $V \neq 0$.

By Lemma 6 we have

$$\begin{aligned} T(r, F) &\leq N_2\left(r, \frac{1}{F}\right) + N_2\left(r, \frac{1}{G}\right) + 2\bar{N}(r, F) \\ &\quad + \bar{N}_L(r, F) + \bar{N}_L(r, G) + S(r, F) + S(r, G). \end{aligned} \quad (25)$$

So

$$\begin{aligned} T(r, F_1) &\leq T(r, F) + \log r \\ &\leq N_2\left(r, \frac{1}{F_1}\right) + N_2\left(r, \frac{1}{G_1}\right) + 2\bar{N}(r, F_1) \\ &\quad + \bar{N}_L(r, F) + \bar{N}_L(r, G) + 3\log r \\ &\quad + S(r, F) + S(r, G). \end{aligned} \quad (26)$$

Obviously,

$$N(r, F_1) = (n+1)N(r, f) + k\bar{N}(r, f) + S(r, f). \quad (27)$$

We have

$$\begin{aligned} nm(r, f) &= m\left(r, \frac{F_1}{f^{(k)}}\right) \\ &\leq m(r, F_1) + m\left(r, \frac{1}{f^{(k)}}\right) + S(r, f) \\ &= m(r, F_1) + T(r, f^{(k)}) - N\left(r, \frac{1}{f^{(k)}}\right) + S(r, f) \\ &\leq m(r, F_1) + T(r, f) + k\bar{N}(r, f) \\ &\quad - N\left(r, \frac{1}{f^{(k)}}\right) + S(r, f), \\ \bar{N}_L(r, F) + \bar{N}_L(r, G) &\leq \bar{N}(r, f). \end{aligned} \quad (28)$$

It follows from (26)–(28) that

$$\begin{aligned} (n-1)T(r, f) &\leq T(r, F_1) - N(r, f) - N\left(r, \frac{1}{f^{(k)}}\right) + S(r, f) \\ &\leq N_2\left(r, \frac{1}{F_1}\right) + N_2\left(r, \frac{1}{G_1}\right) + 2\bar{N}(r, F) - N(r, f) \\ &\quad + \bar{N}_L(r, F) + \bar{N}_L(r, G) + 3\log r - N\left(r, \frac{1}{f^{(k)}}\right) \\ &\quad + S(r, f) + S(r, g) \\ &\leq 2\bar{N}\left(r, \frac{1}{f}\right) + 2\bar{N}\left(r, \frac{1}{g}\right) + N\left(r, \frac{1}{g}\right) + (k+1)\bar{N}(r, f) \\ &\quad + \bar{N}_L(r, F) + \bar{N}_L(r, G) + 3\log r + S(r, f) + S(r, g) \\ &\leq 2\bar{N}\left(r, \frac{1}{f}\right) + 2\bar{N}\left(r, \frac{1}{g}\right) + N\left(r, \frac{1}{g}\right) + (k+2)\bar{N}(r, f) \\ &\quad + 3\log r + S(r, f) + S(r, g). \end{aligned} \quad (29)$$

Similarly we have

$$\begin{aligned} (n-1)T(r, g) &\leq 2\bar{N}\left(r, \frac{1}{f}\right) + 2\bar{N}\left(r, \frac{1}{g}\right) + N\left(r, \frac{1}{f}\right) + (k+1)\bar{N}(r, g) \\ &\quad + \bar{N}_L(r, F) + \bar{N}_L(r, G) + 3\log r + S(r, f) + S(r, g) \\ &\leq 2\bar{N}\left(r, \frac{1}{f}\right) + 2\bar{N}\left(r, \frac{1}{g}\right) + N\left(r, \frac{1}{g}\right) + (k+2)\bar{N}(r, g) \\ &\quad + 3\log r + S(r, f) + S(r, g). \end{aligned} \quad (30)$$

Combining (29) and (30) gives

$$\begin{aligned} (n-1)(T(r, f) + T(r, g)) &\leq 4\left(\bar{N}\left(r, \frac{1}{f}\right) + \bar{N}\left(r, \frac{1}{g}\right)\right) + N\left(r, \frac{1}{f}\right) \\ &\quad + N\left(r, \frac{1}{g}\right) + (k+1)(\bar{N}(r, f) + \bar{N}(r, g)) \\ &\quad + 2(\bar{N}_L(r, F) + \bar{N}_L(r, G)) + 6\log r \\ &\quad + S(r, f) + S(r, g) \\ &\leq 5\left(N\left(r, \frac{1}{f}\right) + N\left(r, \frac{1}{g}\right)\right) \\ &\quad + (k+2)(\bar{N}(r, f) + \bar{N}(r, g)) \\ &\quad + 6\log r + S(r, f) + S(r, g). \end{aligned} \quad (31)$$

From (7) and (31) we get

$$\begin{aligned} & [(n-6)(n-k) - 4(k+2)](T(r, f) + T(r, g)) \\ & \leq 6(n-k) \log r + S(r, f) + S(r, g). \end{aligned} \quad (32)$$

Case 1. Either f or g is transcendental; from (32) we get a contradiction since $n > k + 7 > k + 6$.

Thus $H \equiv 0$. Similar to the proof of [12, Lemma 3], we obtain

$$\begin{aligned} & \text{(i) } f^n f^{(k)} g^n g^{(k)} = z^2, \text{ or} \\ & \text{(ii) } f^n f^{(k)} = g^n g^{(k)}. \end{aligned}$$

By Lemma 10, we get conclusion (2) from (i).

Case 2. Both f and g are rational functions.

If f is a polynomial, so is g . We get from (31) that

$$\begin{aligned} (2k+4) \log r + O(1) & \leq (k+2)(T(r, f) + T(r, g)) \\ & \leq 6 \log r + O(1), \end{aligned} \quad (33)$$

which implies $k = 1$, $T(r, f) = \log r + O(1)$, and $T(r, g) = \log r + O(1)$.

Set

$$f(z) = p_1 z + q_1, \quad g(z) = p_2 z + q_2, \quad (34)$$

where p_1, p_2, q_1, q_2 are constants with $p_1 p_2 \neq 0$. By our assumption, we have

$$f^n f' - z = d(g^n g' - z), \quad (35)$$

where d is a nonzero constant. By computation we have

$$\begin{aligned} p_1^{10-j} q_1^j &= d p_2^{10-j} q_2^j, \quad (j = 0, 1, \dots, 7, 9), \\ 9 p_1^2 q_1^8 - 1 &= d(9 p_2^2 q_2^8 - 1), \end{aligned} \quad (36)$$

which implies $d = 1$ and $f^n f' = g^n g'$; thus $f^{n+1} = g^{n+1} + d_1$ for a constant d_1 . By the second fundamental theorem we get $d_1 = 0$ and $f \equiv tg$ for a constant t such that $t^{n+1} = 1$.

If f and g are nonpolynomial rational functions, set

$$f(z) = \frac{R(z)}{T(z)}, \quad g(z) = \frac{U(z)}{V(z)}, \quad (37)$$

where $R(z), T(z), U(z)$, and $V(z)$ are polynomials. Now we discuss three cases as follows.

Case 2.1. Consider $\deg R > \deg T$.

Case 2.1.1. If $\deg U > \deg V$, from (31) we obtain

$$\begin{aligned} & (k+2)(m(r, f) + m(r, g)) \\ & + (k+2)(N(r, f) - \bar{N}(r, f) + N(r, g) - \bar{N}(r, g)) \\ & \leq 6 \log r + O(1), \end{aligned} \quad (38)$$

which implies that both f and g have only simple poles; thus

$$\bar{N}_L(r, F) + \bar{N}_L(r, G) = 0. \quad (39)$$

From (31) we get

$$\begin{aligned} & (k+1)(m(r, f) + m(r, g)) + T(r, f) + T(r, g) \\ & \leq 6 \log r + O(1), \end{aligned} \quad (40)$$

which is a contradiction since $T(r, f) \geq 2 \log r + O(1)$, $T(r, g) \geq \log r + O(1)$, $m(r, f) \geq \log r + O(1)$, and $m(r, g) \geq \log r + O(1)$.

Case 2.1.2. If $\deg U < \deg V$, from (31) we obtain

$$\begin{aligned} 8 \log r + O(1) & \leq (k+2)m(r, f) + 5m\left(r, \frac{1}{g}\right) \\ & \leq 6 \log r + O(1), \end{aligned} \quad (41)$$

a contradiction.

Case 2.1.3. Consider $\deg U = \deg V$, and $T(r, g) = N(r, g) = \deg U \log r + O(1)$, $m(r, g) = m(r, 1/g) = O(1)$. It follows from (31) that

$$\begin{aligned} & (k+2)m(r, f) \\ & + (k+2)(N(r, f) - \bar{N}(r, f) + N(r, g) - \bar{N}(r, g)) \\ & \leq 6 \log r + O(1). \end{aligned} \quad (42)$$

If $k \geq 2$, then from (42) we get that both f and g have only simple poles; thus

$$\bar{N}_L(r, F) + \bar{N}_L(r, G) = 0. \quad (43)$$

From (31) we get

$$(k+1)m(r, f) + T(r, f) + T(r, g) \leq 6 \log r + O(1), \quad (44)$$

which implies that $k = 2$, $T(r, f) = 2 \log r + O(1)$, $T(r, g) = \log r + O(1)$, and $m(r, f) = \log r + O(1)$. Set

$$f(z) = \frac{b_2 z^2 + b_1 z + b_0}{z - z_0}, \quad g(z) = \frac{c_1 z + c_0}{z - z_0}, \quad (45)$$

where b_2, b_1, b_0, c_1, c_0 , and z_0 are constants with $b_2 c_1 \neq 0$. Therefore, we have

$$f'' = \frac{p_3}{(z - z_0)^3}, \quad g'' = \frac{q_3}{(z - z_0)^3}, \quad (46)$$

where p_3, q_3 are nonzero constants. So $F_1 - z$ has $2n$ zeros and $G_1 - z$ has $n + 4$ zeros, which is a contradiction.

If $k = 1$, then it follows from (42) that either f or g has only a pole of order at most 2, and both f and g can not have a pole of order 2. If f has a pole of order 2, then g has only simple poles. Thus from (42) we get

$$2m(r, f) + T(r, f) + T(r, g) \leq 6 \log r + O(1). \quad (47)$$

Obviously, $m(r, f) = \log r + O(1)$. If $T(r, f) = 3 \log r + O(1)$, then $T(r, g) = \log r + O(1)$. Set

$$f(z) = \frac{b_3 z^3 + b_2 z^2 + b_1 z + b_0}{(z - z_0)^2}, \quad g(z) = \frac{c_1 z + c_0}{z - z_0}, \quad (48)$$

where $b_3, b_2, b_1, b_0, c_1, c_0$, and z_0 are constants with $b_3 c_1 \neq 0$. Therefore, we have

$$f' = \frac{P(z)}{(z - z_0)^3}, \quad g' = \frac{Q(z)}{(z - z_0)^2}, \quad (49)$$

where $P(z)$ is a polynomial with $\deg P = 3$; $Q(z)$ is a nonzero constant. So $F_1 - z$ has $3n + 3$ zeros and $G_1 - z$ has $n + 3$ zeros, which is a contradiction.

If $T(r, f) = 2 \log r + O(1)$, then $T(r, g) = 2 \log r + O(1)$. So we have $T(r, f) \geq N(r, f) > N(r, g) = 2 \log r + O(1)$, a contradiction.

If g has a pole of order 2, then f has only simple poles. With similar discussion as above, we get a contradiction.

Therefore, both f and g have only simple poles and we also get (47). Thus $m(r, f) = \log r + O(1)$. If $T(r, f) = 3 \log r + O(1)$, then $T(r, g) = \log r + O(1)$; we have $T(r, f) = m(r, f) + N(r, f) = m(r, f) + N(r, g) = 2 \log r + O(1)$, which is a contradiction. If $T(r, f) = 2 \log r + O(1)$ and $T(r, g) = 2 \log r + O(1)$, we also get a contradiction. If $T(r, f) = 2 \log r + O(1)$ and $T(r, g) = \log r + O(1)$, then we get (45), which leads to a contradiction.

Case 2.1 has been ruled out.

Case 2.2. Consider $\deg R < \deg T$.

With similar discussion as in Case 2.1, it is easy to get $\deg U = \deg V$. Thus $m(r, f) = m(r, g) = m(r, 1/g) = O(1)$. Then from (31) we get

$$\begin{aligned} & 5m\left(r, \frac{1}{f}\right) \\ & + (k+2) \left(N(r, f) - \overline{N}(r, f) + N(r, g) - \overline{N}(r, g) \right) \\ & \leq 6 \log r + O(1), \end{aligned} \quad (50)$$

which implies that both f and g only have simple poles. Moreover, we have $m(r, 1/f) = \log r + (1)$, and $\overline{N}_L(r, F) = \overline{N}_L(r, G) = 0$. Again from (31) we obtain

$$\begin{aligned} 7 \log r + O(1) & \leq 5m\left(r, \frac{1}{f}\right) + T(r, f) + T(r, g) \\ & \leq 6 \log r + O(1), \end{aligned} \quad (51)$$

which is a contradiction.

Case 2.2 has been ruled out.

Case 2.3. Thus we have $\deg R = \deg T$. Similarly, we have $\deg U = \deg V$.

It follows from (31) that

$$\begin{aligned} & (k+2) \left(N(r, f) - \overline{N}(r, f) + N(r, g) - \overline{N}(r, g) \right) \\ & \leq 6 \log r + O(1). \end{aligned} \quad (52)$$

Now we prove that f and g share ∞ CM. We discuss two cases below.

Case 2.3.1. If $k \geq 2$, (52) implies that neither f nor g has a pole of order greater than 2; both f and g can not have poles of order 2. Thus only one of f and g may have a pole of order 2.

Suppose that

$$\begin{aligned} f(z) &= \frac{b_{l+1} z^{l+1} + b_l z^l + \cdots + b_0}{(z - z_1)^2 (z - z_2) \cdots (z - z_l)}, \\ g(z) &= \frac{c_l z^l + c_{l-1} z^{l-1} + \cdots + c_0}{(z - z_1) (z - z_2) \cdots (z - z_l)}. \end{aligned} \quad (53)$$

We deduce from (53) that

$$\begin{aligned} F_1 &= \frac{P_1(z)}{(z - z_1)^{2+k} (z - z_2)^{1+k} \cdots (z - z_l)^{1+k}}, \\ G_1 &= \frac{Q_1(z)}{(z - z_1)^{1+k} (z - z_2)^{1+k} \cdots (z - z_l)^{1+k}}, \end{aligned} \quad (54)$$

where $P_1(z), Q_1(z)$ are polynomials with $\deg P_1 \leq (1+k)(l+1) - 2k - 1$, $\deg Q_1 \leq (1+k)l - 2k - 1$. We get that $F_1 - z$ has $(1+n+k)(l+1) - k + 1$ zeros while $G_1 - z$ has $(1+n+k)l + 1$ zeros, which is a contradiction because F_1 and G_1 share z CM. Thus f has only simple poles. Similarly, g has only simple poles; thus f and g share ∞ CM.

Case 2.3.2. If $k = 1$, (31) implies that

$$\begin{aligned} & 2 \left(N(r, f) - \overline{N}(r, f) + N(r, g) - \overline{N}(r, g) \right) \\ & + T(r, f) + T(r, g) \\ & \leq 2 \left(\overline{N}_L(r, F) + \overline{N}_L(r, G) \right) + 6 \log r + O(1). \end{aligned} \quad (55)$$

If f and g do not share ∞ CM, and if g only has simple poles, (55) leads to

$$\begin{aligned} & 2 \left(N(r, f) - \overline{N}(r, f) \right) + T(r, f) + T(r, g) \\ & \leq 2 \overline{N}_L(r, F) + 6 \log r + O(1). \end{aligned} \quad (56)$$

If f has m poles of order $p_m \geq 3$, then from (56) we get $m = 1$, $T(r, f) = 3 \log r + O(1)$, and $T(r, g) = \log r + O(1)$. Set

$$f(z) = \frac{b_3 z^3 + b_2 z^2 + b_1 z + b_0}{(z - z_0)^3}, \quad g(z) = \frac{c_1 z + c_0}{z - z_0}. \quad (57)$$

With the similar discussion in Case 2.3.1 we get a contradiction.

If f has m poles of order 2, then from (56) we get $m \leq 2$.

If $m = 2$, then $T(r, f) = 4 \log r + O(1)$ and $T(r, g) = 2 \log r + O(1)$. Set

$$\begin{aligned} f(z) &= \frac{b_4 z^4 + b_3 z^3 + b_2 z^2 + b_1 z + b_0}{(z - z_1)^2 (z - z_2)^2}, \\ g(z) &= \frac{c_2 z^2 + c_1 z + c_0}{(z - z_1) (z - z_2)}. \end{aligned} \quad (58)$$

With the similar discussion in Case 2.3.1 we get a contradiction.

If $m = 1$, we get (53); with a similar discussion in Case 2.3.1 we get a contradiction.

So g must have multiple poles. Similarly, f must have multiple poles.

From (52) we get that both f and g have one and only one multiple pole and their order is 2. Since the multiple poles are distinct, then from (55) we get

$$\begin{aligned} f &= a \frac{(z - a_1)(z - a_2)(z - a_3)}{(z - d_1)^2(z - d_2)}, \\ g &= b \frac{(z - b_1)(z - b_2)(z - b_3)}{(z - d_1)(z - d_2)^2}, \end{aligned} \quad (59)$$

provided that $n = 9$, where a_j, b_j ($j = 1, 2, 3$), d_1, d_2 are 8 distinct constants and a, b are two nonzero constants. By our assumption, this case has been ruled out. So f and g share ∞ CM.

We have

$$F_1 = \frac{P_2(z)}{Q_2(z)}, \quad G_1 = \frac{P_3(z)}{Q_2(z)}, \quad (60)$$

where $P_2(z)$, $P_3(z)$, and $Q_2(z)$ are polynomials with $\deg P_2 < \deg Q_2$, $\deg P_3 < \deg Q_2$. Since F_1 and G_1 share z CM, we have

$$P_2(z) - zQ_2(z) = c(P_3(z) - zQ_2(z)), \quad (61)$$

where c is a nonzero constant; then we get

$$P_2(z) - cP_3(z) = (1 - c)zQ_2(z), \quad (62)$$

which implies $c = 1$ and $P_2(z) = P_3(z)$. Thus $f^n f^{(k)} = g^n g^{(k)}$.

This completes the proof of Theorem 2.

4. Discussion

Remark 11. The author can not assert whether (1) really exists because the calculation is rather complicated. The possibility of the existence of (1) is small because the 10 constants must satisfy at least 34 equations. Unfortunately, the author can not prove it. If there exists exceptional case (1), it has its own meaning. It will show that the condition “ $n \geq 11$ ” of Theorem B can not be reduced to $n \geq 9$.

Remark 12. One can not get $f \equiv tg$ for a constant t from $f^n f^{(k)} = g^n g^{(k)}$. For example, let $f(z) = P(z)$, $g(z) = Q(z)$, where $P(z)$ and $Q(z)$ are polynomials with $\max\{\deg P, \deg Q\} < k$. Then $f \not\equiv tg$ for a constant t but we still have $f^n f^{(k)} = g^n g^{(k)}$.

Problem 4. Can $f^n f^{(k)} = g^n g^{(k)}$ guarantee $f \equiv tg$ for a constant t when f and g are transcendental meromorphic functions?

Conflict of Interests

The author declares that there is no conflict of interests regarding the publication of this paper.
