The skew-circulant matrix has been used in solving ordinary differential equations. We prove that the set of skew-circulants with complex entries has an idempotent basis. On that basis, a skew-cyclic group of automorphisms and functional equations on the skew-circulant algebra is introduced. And different operators on linear vector space that are isomorphic to the algebra of $n \times n$ complex skew-circulant matrices are displayed in this paper.

1. Introduction

Skew circulant and circulant matrices have become important tools in solving various differential equations. Bertaccini and Ng [1] proposed a nonsingular skew-circulant preconditioner for systems of LMF-based ODE codes. Delgado et al. [2] developed some techniques to obtain global hyperbolicity for a certain class of endomorphisms of $(\mathbb{R}^p)^n$ with $p, n \geq 2$; this kind of endomorphisms is obtained from vectorial difference equations where the mapping defining these equations satisfies a circulant matrix condition. Wilde [3] developed a theory for the solution of ordinary and partial differential equations whose structure involves the algebra of circulants. He showed how the algebra of 2×2 circulants relates to the study of the harmonic oscillator, the Cauchy-Riemann equations, Laplace's equation, the Lorentz transformation, and the wave equation. And he used $n \times n$ circulants to suggest natural generalizations of these equations to higher dimensions. Using circulant matrix, Karasözen and Şimşek [4] considered periodic boundary conditions such that no additional boundary terms will appear after semidiscretization. In [5], the resulting dense linear system exhibits so much structure that it can be solved very efficiently by a circulant preconditioned conjugate gradient method. Brockett and Willems [6] showed how the important problems of linear system theory can be solved concisely for a particular class of

linear systems, namely, block circulant systems, by exploiting the algebraic structure. Circulant matrices were also used to solve linear systems from differential-algebraic equations and delay differential equations; see [7, 8].

Skew circulant matrices have important applications in various disciplines including image processing, communications, signal processing, encoding, solving Toeplitz matrix problems, preconditioner, and solving least squares problems. They have been put on firm basis with the work of Davis [9] and Jiang and Zhou [10]. Hermitian and skew-Hermitian Toeplitz systems are considered in [11–13]. Lyness and Sørøvik [14] employed a skew circulant matrix to construct s -dimensional lattice rules. Spectral decompositions of skew circulant and skew left circulant matrices were discussed in [15]. Compared with cyclic convolution algorithm, the skew cyclic convolution algorithm [16] is able to perform filtering procedure in approximately half of computational cost for real signals. In [17] two new normal-form realizations are presented by utilizing circulant and skew circulant matrices as their state transition matrices. The well-known second-order coupled form is a special case of the skew circulant form. Li et al. [18] gave the style spectral decomposition of skew circulant matrix firstly and then dealt with the optimal backward perturbation analysis for the linear system with skew circulant coefficient matrix. In [19], a new fast

algorithm for optimal design of block digital filters (BDFs) is proposed based on skew circulant matrix. Gao et al. [20] gave explicit determinants and inverses of skew circulant and skew left circulant matrices with Fibonacci and Lucas numbers.

Besides, there are several papers on the circulant operator and circulant algebra. Wilde [21] discussed aspects of functional equations obtaining generalizations of odd and even functions in terms of n th roots of unity in complex number field. Wilde [22, 23] generalized properties of 2×2 circulant matrices and 2-dimensional complex analysis to $n \times n$ circulant matrices. Wilde [24] displayed algebras of operators which are isomorphic to the algebra of $n \times n$ complex circulant matrices. Chan et al. [25] gave different formulations of the operator, discussed its algebraic and geometric properties, and computed its operator norms in different Banach algebras of matrices. Using these results, they also gave an efficient algorithm for finding the superoptimal circulant preconditioner. Chillag [26] proved that eigenvalues of some generalized circulant matrices and the Matteson-Solomon coefficients of a codeword of a cyclic code are all examples of eigenvalues of elements of semisimple finite-dimensional, commutative algebras. The purpose of Chillag's paper is to exhibit elementary properties of such algebras and to apply these properties in various situations. Brink and Pretorius [27] embed some results on Boolean circulants into the context of relation algebras and then generalised them. Interestingly enough, the route lies in group theory. Chan et al. [28] studied the solutions of finite-section Wiener-Hopf equations, by the preconditioned conjugate gradient method, and gave an easy and general scheme of constructing good circulant integral operators as preconditioners for such equations. Benedetto and Capizzano [29] investigated algebraic and geometric properties of the optimal approximation operator, generalizing those proved in [25] for the basic circulant case. Benedetto and Capizzano [30] considered the superoptimal Frobenius operators in several matrix vector spaces and in particular in the circulant algebra, by emphasizing both the algebraic and geometric properties. Hwang et al. [31] are concerned with the hyponormality of Toeplitz operators with matrix-valued circulant symbols. They established a necessary and sufficient condition for Toeplitz operators with matrix-valued partially circulant symbols to be hyponormal and provided a rank formula for the self-commutator. Several norm equalities and inequalities for operator matrices are proved in [32]. These results, which depend on the structure of circulant and skew circulant operator matrices, include pinching type inequalities for weakly unitarily invariant norms.

In passing, skew-circulant operator and algebra were only used in [32]. And solving differential equations by skew circulant matrices has not been fully exploited (as far as we known, only in [1]). It is hoped that this paper will help in changing this. More work continuing the present paper is forthcoming.

In Section 2, we will prove that a complex $n \times n$ skew-circulant matrix is a matrix representation of the group ring (over $\mathbb{C}$) of the skew cyclic group. We also prove that the set

of skew-circulants with complex entries has an idempotent basis.

In Section 3, functional equations, whose solutions are functions $\mathbb{C}^n \rightarrow \mathbb{C}$, are solved using skew-cyclic and idempotent linear operators on the space (labeled U) of functions $\mathbb{C}^n \rightarrow \mathbb{C}$. Further, we will show that this algebra of linear operators is isomorphic to $n \times n$ skew-circulants.

In Section 4, we display skew cyclic and idempotent linear operators on the space V of functions on $n \times n$ complex skew-circulants. Furthermore, we get a relationship between the operators on V and those on U .

In Section 5, we show a linear involution on V whose group ring is isomorphic to 2×2 complex skew-circulant matrices.

2. Properties of Skew-Circulant

An $n \times n$ skew-circulant matrix is a square matrix like the following:

$$S = \begin{pmatrix} x_0 & x_1 & \cdots & x_{n-1} \\ -x_{n-1} & x_0 & \cdots & x_{n-2} \\ -x_{n-2} & -x_{n-1} & \cdots & x_{n-3} \\ \vdots & \vdots & \vdots & \vdots \\ -x_1 & -x_2 & \cdots & x_0 \end{pmatrix}_{n \times n}. \quad (1)$$

Let S_n denote the set of skew-circulant matrices with complex entries. Let π denote the skew-circulant matrix with $x_1 = 1$ and $x_j = 0$ for $j \neq 1$. Then π^l (the l th power of π , $1 \leq l < n$) is the skew-circulant matrix with $x_l = 1$ and $x_j = 0$ for all $j \neq l$, $\pi^0 = I$ (I is the identity matrix), $\pi^1 = \pi$, and $\pi^n = -I$. So S can be written as

$$S = \sum_{l=0}^{n-1} x_l \pi^l, \quad (2)$$

for $x_0, x_1, \dots, x_{n-1} \in \mathbb{C}$. In other words, $\pi_0, \pi_1, \pi_2, \dots, \pi_{n-1}$ form a basis for the set of skew-circulant matrices. Let ω denote any of the n th roots of unit, or $\omega = e^{2\pi i/n}$, $\eta = e^{\pi i/n}$, and

$$y_l = \sum_{j=0}^{n-1} \eta^j \omega^{lj} x_j, \quad \text{for } l = 0, 1, \dots, n-1. \quad (3)$$

Then, through the eigenvalues of the matrix π_i , $i = 0, 1, \dots, n-1$, we know that the numbers $y_0, y_1, \dots, y_{n-1}$ are the eigenvalues of the skew-circulant matrix S .

Proposition 1. *If S_n , the set of skew-circulant matrices, has a basis $\pi_0, \pi_1, \pi_2, \dots, \pi_{n-1}$, then the S_n also has another basis $G_0, G_1, \dots, G_{n-1}$, where*

$$G_l = \frac{1}{n} \sum_{j=0}^{n-1} (\eta^{-j} \omega^{-lj} \pi^j), \quad (4)$$

for $\omega = e^{2\pi i/n}$, $\eta = e^{\pi i/n}$, and $l = 0, 1, \dots, n-1$.

Proof. By calculation, these matrices G_l ($l = 0, 1, 2, \dots, n-1$) have the following properties:

$$\begin{aligned} G_l^2 &= G_l, \quad \text{for } l = 0, 1, 2, \dots, n-1; \\ G_l G_i &= 0, \quad \text{for } l \neq i; \\ G_0 + G_1 + G_2 + \dots + G_{n-1} &= I; \\ \pi^l &= \sum_{j=0}^{n-1} \eta^j \omega^{lj} G_j, \end{aligned} \quad (5)$$

for $l = 0, 1, \dots, n-1$. Thus, the idempotents $G_0, G_1, \dots, G_{n-1}$ form a basis for S_n , and in (2) we also have

$$S = \sum_{l=0}^{n-1} y_l G_l = y_0 G_0 + \dots + y_{n-1} G_{n-1}. \quad (6)$$

□

We have seen that every skew-circulant matrix, $S \in S_n$, can be written in one and only one way in the form (2); that is

$$S = x_0 I + x_1 \pi + x_2 \pi^2 + \dots + x_{n-1} \pi^{n-1}. \quad (7)$$

Proposition 2. If the function $\phi : S_n \rightarrow S_n$ is defined by

$$\phi(S) = \eta x_0 I + \eta \omega x_1 \pi + \dots + \eta \omega^{n-1} x_{n-1} \pi^{n-1}, \quad (8)$$

then $\phi^n(S) = -S$.

Proof. By composition, we gain that

$$\begin{aligned} \phi^k(S) &= \eta^k x_0 I + \eta^k \omega^k x_1 \pi + \eta^k \omega^{2k} x_2 \pi^2 \\ &\quad + \dots + \eta^k \omega^{(n-1)k} x_{n-1} \pi^{n-1}; \end{aligned} \quad (9)$$

that is, ϕ^k replaces x_l by $\eta^k \omega^{lk} x_l$ for $l = 0, 1, 2, \dots, n-1$. Also, $\phi^n(S) = -S$. □

The function ϕ is an automorphism in S_n that preserves $\mathbf{C}$, with $\mathbf{C}$ being embedded in S_n by the correspondence $c \rightarrow cI$ for $c \in \mathbf{C}$.

Proposition 3. Let p_l be the function $S_n \rightarrow S_n$ defined by

$$p_l = \frac{1}{n} \sum_{j=0}^{n-1} \eta^{-j} \omega^{-lj} \phi^j, \quad \text{for } l = 0, 1, \dots, n-1. \quad (10)$$

Then,

$$\begin{aligned} p_l^2 &= p_l, \quad \text{for } l = 0, 1, 2, \dots, n-1; \\ p_l p_j &= 0, \quad \text{for } l \neq j; \end{aligned}$$

$$\begin{aligned} p_0 + p_1 + p_2 + \dots + p_{n-1} &= \phi^0; \\ \eta^l p_0 + \eta^l \omega^l p_1 + \dots + \eta^l \omega^{(n-1)l} p_{n-1} &= \phi^l; \\ p_l (x_0 I + x_1 \pi + \dots + x_{n-1} \pi^{n-1}) &= x_l \pi^l, \end{aligned} \quad (11)$$

for $l = 0, 1, \dots, n-1$.

Proof. Since $p_l = (1/n) \sum_{j=0}^{n-1} \eta^{-j} \omega^{-lj} \phi^j$, we gain that

$$\begin{aligned} p_l^2 &= \frac{1}{n^2} [\phi^0 + \eta^{-1} \omega^{-l} \phi + \dots + \eta^{-(n-1)} \omega^{-(n-1)l} \phi^{n-1}]^2 \\ &= \frac{1}{n^2} [\phi^0 + \eta^{-1} \omega^{-l} \phi + \dots + \eta^{-(n-1)} \omega^{-(n-1)l} \phi^{n-1} \\ &\quad + \eta^{-1} \omega^{-l} \phi + \dots + \eta^{-n} \omega^{-nl} \phi^n \\ &\quad + \dots + \eta^{-(n-1)} \omega^{-(n-1)l} \phi^{n-1} \\ &\quad + \dots + \eta^{-2(n-1)} \omega^{-2(n-1)l} \phi^{2(n-1)}] \\ &= p_l. \end{aligned} \quad (12)$$

Similarly, we can obtain $p_l p_j = 0$ for $l \neq j$. And, by calculation, we have

$$\begin{aligned} p_0 + p_1 + \dots + p_{n-1} &= \frac{1}{n} \left[\sum_{j=0}^{n-1} \eta^{-j} \phi^j + \dots + \sum_{j=0}^{n-1} \omega^{-(n-1)j} \eta^{-j} \phi^j \right] \\ &= \frac{1}{n} \left[\sum_{j=0}^{n-1} \eta^{-j} \phi^j (\omega^0 + \omega^{-j} + \dots + \omega^{-(n-1)j}) \right] \\ &= \frac{1}{n} \left[\sum_{j=0}^{n-1} \eta^{-j} \phi^j \left(\frac{1 - \omega^{-nj}}{1 - \omega^{-j}} \right) \right] \\ &= \phi^0, \\ \eta^l p_0 + \eta^l \omega^l p_1 + \eta^l \omega^{2l} p_2 + \dots + \eta^l \omega^{(n-1)l} p_{n-1} &= \frac{1}{n} \left[\sum_{j=0}^{n-1} \eta^l \phi^j + \sum_{j=0}^{n-1} \eta^l \phi^j + \dots + \sum_{j=0}^{n-1} \eta^l \phi^j \right] \\ &= \phi^l. \end{aligned} \quad (13)$$

Finally, we gain

$$\begin{aligned} p_l (x_0 I + x_1 \pi + x_2 \pi^2 + \dots + x_{n-1} \pi^{n-1}) &= \frac{1}{n} \sum_{j=0}^{n-1} \eta^{-j} \omega^{-lj} \phi^j(S) \end{aligned}$$

$$\begin{aligned}
&= \frac{1}{n} \left[x_0 I + x_1 \pi + x_2 \pi^2 + \cdots + x_{n-1} \pi^{n-1} \right. \\
&\quad + \eta^{-1} \omega^{-l} \left(\eta x_0 I + \eta \omega x_1 \pi + \cdots + \eta \omega^{n-1} x_{n-1} \pi^{n-1} \right) \\
&\quad + \cdots + \eta^{-(n-1)} \omega^{-(n-1)l} \left(\eta^{n-1} x_0 I + \eta^{n-1} \omega^{n-1} x_1 \pi \right. \\
&\quad \left. \left. + \cdots + \eta^{n-1} \omega^{(n-1)^2} x_{n-1} \pi^{n-1} \right) \right] \\
&= x_l \pi^l.
\end{aligned} \tag{14}$$

Synthesizing Propositions 1, 2, and 3, we get the following theorem.

Theorem 4. *The algebras generated by $I, \pi, \pi^2, \dots, \pi^{n-1}$ and $\phi^0, \phi^1, \phi^2, \dots, \phi^{n-1}$ over $\mathbf{C}$ are isomorphic and can be called skew-circulant algebras.*

3. Functional Equations for the Skew-Circulant Algebra

Proposition 5. *If f is a linear entire function, $f : \mathbf{C} \rightarrow \mathbf{C}$, then*

$$\begin{aligned}
&f(c_0 I + c_1 \pi + \cdots + c_{n-1} \pi^{n-1}) \\
&= \sum_{l=0}^{n-1} \left[\frac{1}{n} \sum_{j=0}^{n-1} \eta^{-j} \omega^{-lj} f \left(\sum_{k=0}^{n-1} \eta^k \omega^{jk} c_k \right) \right] \pi^l.
\end{aligned} \tag{15}$$

Proof. According to [3], we know that

$$\begin{aligned}
\lambda_l &= \sum_{j=0}^{n-1} \eta^j \omega^{lj} c_j, \\
c_l &= \frac{1}{n} \sum_{j=0}^{n-1} \eta^{-j} \omega^{-lj} \lambda_j,
\end{aligned} \tag{16}$$

for $l = 0, 1, \dots, n-1$.

We thus have

$$\begin{aligned}
\sum_{l=0}^{n-1} f(c_l) \pi^l &= \sum_{l=0}^{n-1} f \left(\frac{1}{n} \sum_{j=0}^{n-1} \eta^{-j} \omega^{-lj} \lambda_j \right) \pi^l \\
&= \sum_{l=0}^{n-1} \frac{1}{n} \sum_{j=0}^{n-1} \eta^{-j} \omega^{-lj} f(\lambda_j) \pi^l \\
&= \sum_{l=0}^{n-1} \left[\frac{1}{n} \sum_{j=0}^{n-1} \eta^{-j} \omega^{-lj} f \left(\sum_{k=0}^{n-1} \eta^k \omega^{jk} c_k \right) \right] \pi^l.
\end{aligned} \tag{17}$$

Then, we complete the proof of this conclusion. $\square$

For any linear entire function $f : \mathbf{C} \rightarrow \mathbf{C}$, (15) can be written as follows:

$$\begin{aligned}
&f(c_0 I + c_1 \pi + \cdots + c_{n-1} \pi^{n-1}) \\
&= \sum_{l=0}^{n-1} F_l(c_0, c_1, \dots, c_{n-1}) \pi^l,
\end{aligned} \tag{18}$$

where

$$\begin{aligned}
&F_l(c_0, c_1, \dots, c_{n-1}) \\
&= \frac{1}{n} \sum_{k=0}^{n-1} \eta^{-k} \omega^{-lk} f \left(\sum_{j=0}^{n-1} \eta^j \omega^{jk} c_j \right),
\end{aligned} \tag{19}$$

$l = 0, 1, 2, \dots, n-1$.

For each l , $F_0, F_1, \dots, F_{n-1}$ satisfy the functional equation

$$\begin{aligned}
&F_l(\eta c_0, \eta \omega c_1, \eta \omega^2 c_2, \dots, \eta \omega^{n-1} c_{n-1}) \\
&= \eta \omega^l F_l(c_0, c_1, \dots, c_{n-1}),
\end{aligned} \tag{20}$$

for $\eta = e^{\pi i/n}$, $\omega = e^{2\pi i/n}$, all $l = 0, 1, 2, \dots, n-1$, and all $c_0, c_1, \dots, c_{n-1} \in \mathbf{C}$.

Equation (20) is related to the skew-circulant algebra also in another way.

If the function F is defined by

$$F(c_0, c_1, \dots, c_{n-1}) = \frac{1}{n} \sum_{k=0}^{n-1} \eta^{-k} \omega^{-lk} f \left(\sum_{j=0}^{n-1} \eta^j \omega^{jk} c_j \right), \tag{21}$$

let $U = \{F : \mathbf{C}^n \rightarrow \mathbf{C}\}$ and let O be the operator $O : U \rightarrow U$, linear in F , defined by

$$\begin{aligned}
&O(F)(c_0, c_1, \dots, c_{n-1}) \\
&= F(\eta c_0, \eta \omega c_1, \eta \omega^2 c_2, \dots, \eta \omega^{n-1} c_{n-1});
\end{aligned} \tag{22}$$

that is,

$$O(F) = \eta \omega^l F. \tag{23}$$

If we denote O^k the operation O composed with itself k times, then

$$\begin{aligned}
&O^k(F)(c_0, c_1, c_2, \dots, c_{n-1}) \\
&= F(\eta^k c_0, \eta^k \omega^k c_1, \dots, \eta^k \omega^{(n-1)k} c_{n-1}),
\end{aligned} \tag{24}$$

where $O^j = -O^0$ if and only if n divides j and j/n is an odd number; $O^j = O^0$ if and only if n divides j and j/n is an even number.

All these equations (15)–(24) lead up to the following theorem.

Theorem 6. *Linear combinations of the operators $O^0, O^1, \dots, O^{n-1}$ over $\mathbb{C}$ form a skew-circulant algebra.*

Proposition 7. *If the operators $R_0, R_1, \dots, R_{n-1} : U \rightarrow U$ are defined by*

$$R_l = \frac{1}{n} \left(O^0 + \eta^{-1} \omega^{-l} O^1 + \eta^{-2} \omega^{-2l} O^2 + \dots + \eta^{-(n-1)} \omega^{-(n-1)l} O^{n-1} \right), \quad (25)$$

for $l = 0, 1, 2, \dots, n-1$, then these operators R_l ($l = 0, 1, 2, \dots, n-1$) have the following properties:

$$R_l^2 = R_l, \quad \text{for } l = 0, 1, 2, \dots, n-1; \quad (26)$$

$$R_l R_j = 0 \quad \text{if } l \neq j; \quad (27)$$

$$R_0 + R_1 + \dots + R_{n-1} = O^0; \quad (28)$$

$$R_0 + \eta \omega^l R_1 + \dots + \eta^{n-1} \omega^{(n-1)l} R_{n-1} = O^l, \quad (29)$$

for $l = 0, 1, 2, \dots, n-1$.

Through simple calculation, we can get properties (26)–(28). Properties (26)–(29) are similar to those of the functions $G_0, G_1, \dots, G_{n-1}$ and $p_0, p_1, \dots, p_{n-1}$.

By all accounts, a function F in U satisfies (20) if and only if $F \in \text{Ran} R_l$ (the range of the operator R_l was denoted by $\text{Ran} R_l$). Moreover, properties (26)–(28) above imply that $U = \text{Ran} R_0 \oplus \text{Ran} R_1 \oplus \dots \oplus \text{Ran} R_{n-1}$, each function F_l , $l = 0, 1, 2, \dots, n-1$, defined by (19) is in $\text{Ran} R_l$.

In addition,

$$\begin{aligned} F_0 + F_1 + \dots + F_{n-1} \\ = f(c_0 + \eta c_1 + \dots + \eta^{n-1} c_{n-1}). \end{aligned} \quad (30)$$

Thus

$$F_l = R_l(f(c_0 + \eta c_1 + \dots + \eta^{n-1} c_{n-1})). \quad (31)$$

4. Other Skew-Circulant Algebras

By (25) and (24), if a function g maps $\mathbb{C}^n$ into $\mathbb{C}$, then

$$\begin{aligned} R_l(g)(c_0, c_1, \dots, c_{n-1}) \\ = \frac{1}{n} \sum_{k=0}^{n-1} \eta^{-k} \omega^{-lk} g(\eta^k c_0 + \eta^k \omega c_1 + \eta^k \omega^2 c_2 + \dots \\ + \eta^k \omega^{(n-1)k} c_{n-1}), \end{aligned} \quad (32)$$

for $l = 0, 1, 2, \dots, n-1$.

For $f : S_n \rightarrow S_n$, S_n is the space of skew-circulant matrices, there exist functions $f_0, f_1, f_2, \dots, f_{n-1} : \mathbb{C}^n \rightarrow \mathbb{C}$ such that

$$f\left(\sum_{l=0}^{n-1} c_l \pi^l\right) = \sum_{l=0}^{n-1} f_l(c_0, c_1, c_2, \dots, c_{n-1}) \pi^l. \quad (33)$$

Hence, from (28),

$$\begin{aligned} f\left(\sum_{l=0}^{n-1} c_l \pi^l\right) &= \sum_{l=0}^{n-1} \sum_{i=0}^{n-1} R_{l+i}(f_l) \pi^l \\ &= \sum_{i=0}^{n-1} \sum_{l=0}^{n-1} R_{l+i}(f_l) \pi^l. \end{aligned} \quad (34)$$

Proposition 8. *Let $V = \{f \mid f : S_n \rightarrow S_n, S_n \text{ is the space of skew-circulant matrices}\}$, for $f \in V$; let us define $q_i(f)$ and g_i such that*

$$q_i(f) \left(\sum_{l=0}^{n-1} c_l \pi^l \right) = \sum_{l=0}^{n-1} R_{l+i}(f_l) \pi^l, \quad (35)$$

$$g_i = \sum_{l=0}^{n-1} R_{l+i}(f_l), \quad (36)$$

for $i = 0, 1, 2, \dots, n-1$ and $l+i$ taken modulo n . Then we can receive the properties of the q_i :

$$\begin{aligned} q_i^2 &= q_i \quad \text{for } i = 0, 1, 2, \dots, n-1; \\ q_i q_j &= 0 \quad \text{if } i \neq j; \end{aligned} \quad (37)$$

$$(q_0 + q_1 + q_2 + \dots + q_{n-1})(f) = f, \quad f \in V.$$

From what has been discussed above, we gain the following theorem.

Theorem 9. *The $q_0, q_1, q_2, \dots, q_{n-1}$ are orthogonal projections on V , adding to the identity function on V , and so generating over $\mathbb{C}$ a skew-circulant algebra.*

Proposition 10. *The projections $q_i(f)$ have another formula as follows:*

$$\begin{aligned} q_i(f) \left(\sum_{l=0}^{n-1} c_l \pi^l \right) &= \frac{1}{n} \sum_{k=0}^{n-1} \omega^{-ik} \phi^{-k} f \phi^k \left(\sum_{l=0}^{n-1} c_l \pi^l \right), \\ i &= 0, 1, \dots, n-1. \end{aligned} \quad (38)$$

Proof. We can prove (38) in the following:

$$\begin{aligned}
q_i(f) \left(\sum_{l=0}^{n-1} c_l \pi^l \right) &= \sum_{l=0}^{n-1} R_{l+i}(f_l) \pi^l \\
&= \sum_{l=0}^{n-1} \left[\frac{1}{n} \sum_{k=0}^{n-1} \eta^{-k} \omega^{-(l+i)k} f_l \left(\eta^k c_0, \eta^k \omega^k c_1, \dots, \right. \right. \\
&\quad \left. \left. \eta^k \omega^{(n-1)k} c_{n-1} \right) \right] \pi^l \\
&= \frac{1}{n} \sum_{l=0}^{n-1} \left[\sum_{k=0}^{n-1} \eta^{-k} \omega^{-lk} \omega^{-ik} f_l \left(\eta^k c_0, \dots, \right. \right. \\
&\quad \left. \left. \eta^k \omega^{(n-1)k} c_{n-1} \right) \right] \pi^l \\
&= \frac{1}{n} \sum_{k=0}^{n-1} \eta^{-k} \omega^{-ik} \sum_{l=0}^{n-1} \omega^{-lk} f_l \left(\eta^k c_0, \eta^k \omega^k c_1, \dots, \right. \\
&\quad \left. \eta^k \omega^{(n-1)k} c_{n-1} \right) \pi^l \\
&= \frac{1}{n} \sum_{k=0}^{n-1} \omega^{-ik} \phi^{-k} f \left(\sum_{l=0}^{n-1} \eta^k \omega^{lk} c_l \pi^l \right) \\
&= \frac{1}{n} \sum_{k=0}^{n-1} \omega^{-ik} \phi^{-k} f \phi^k \left(\sum_{l=0}^{n-1} c_l \pi^l \right). \tag{39}
\end{aligned}$$

□

This result can be rewritten in the form

$$q_i(f) \left(\sum_{l=0}^{n-1} c_l \pi^l \right) = \frac{1}{n} \sum_{k=0}^{n-1} \omega^{-ik} \phi^{-k} f \phi^k, \tag{40}$$

$i = 0, 1, \dots, n-1$, for all functions $f \in V$.

Finally, it can be shown that $f\phi = \omega^i \phi f$ if and only if $f \in \text{Ran } p_i$.

Theorem 11. For each $f \in V$ and every $i = 0, 1, 2, \dots, n-1$, there exists only one function g_i such that the following equation holds:

$$q_i(f) \left(\sum_{l=0}^{n-1} c_l \pi^l \right) = \sum_{l=0}^{n-1} R_{l+i}(g_i) \pi^l, \tag{41}$$

for $g_i = \sum_{l=0}^{n-1} R_{l+i}(f_l)$, $i = 0, 1, 2, \dots, n-1$ and $l+i$ taken modulo n .

Proof. By (26) and (27),

$$R_{l+i}(g_i) = R_{l+i}(f_l) \tag{42}$$

for $l = 0, 1, 2, \dots, n-1$; $i = 0, 1, 2, \dots, n-1$ and $l+i$ taken modulo n .

Suppose there exists another function $g_i^* : \mathbf{C}^n \rightarrow \mathbf{C}$ such that $q_i(f) = \sum_{l=0}^{n-1} R_{l+i}(g_i) \pi^l = \sum_{l=0}^{n-1} R_{l+i}(g_i^*) \pi^l$. Since $I, \pi, \pi^2, \dots, \pi^{n-1}$ is a basis of S_n , $R_{l+i}(g_i) = R_{l+i}(g_i^*)$ for $l = 0, 1, \dots, n-1$. By (28),

$$g_i = \sum_{l=0}^{n-1} R_{l+i}(g_i) = \sum_{l=0}^{n-1} R_{l+i}(g_i^*) = g_i^*. \tag{43}$$

So g_i is unique. Thus, there is an isomorphism between functions $g_i : \mathbf{C}^n \rightarrow \mathbf{C}$ and functions $\sum_{l=0}^{n-1} R_{l+i}(g_i) \pi^l$ in $\text{Ran } q_i$. □

Now the results of all this are as follows: let $\Phi = \{f \mid f : \mathbf{C} \rightarrow \mathbf{C}\}$ with f an entire function and $U = \{f \mid f : \mathbf{C}^n \rightarrow \mathbf{C}\}$. Let I be a monomorphism $\Phi \rightarrow U^n$ defined by $I(f) = (f(c_0 + \eta c_1 + \dots + \eta^{n-1} c_{n-1}), 0, \dots, 0)$. Let τ be a monomorphism $\Phi \rightarrow V$ defined by

$$\begin{aligned}
\tau(f) \left(\sum_{l=0}^{n-1} c_l \pi^l \right) &= \sum_{l=0}^{n-1} R_n \left(f \left(c_0 + \eta c_1 + \dots + \eta^{n-1} c_{n-1} \right) \right) \pi^l \\
&= f \left(\sum_{l=0}^{n-1} c_l \pi^l \right), \tag{44}
\end{aligned}$$

which follows from (18), (19), and (31). Then there exists an isomorphism $\theta : U^n \rightarrow V$ defined by

$$\begin{aligned}
\theta(g_0, g_1, g_2, \dots, g_{n-1}) \left(\sum_{l=0}^{n-1} c_l \pi^l \right) &= \sum_{i=0}^{n-1} \sum_{l=0}^{n-1} R_{l+i}(g_i) \pi^l. \tag{45}
\end{aligned}$$

5. A Linear Involution

Suppose that g is a function $S_n \rightarrow S_n$ given by

$$g = \sum_{i=0}^{n-1} g_i \pi^i, \tag{46}$$

where g_i is given by (36). Written out, we have

$$g = \sum_{i=0}^{n-1} \left[\sum_{l=0}^{n-1} R_{l+i}(f_l) \right] \pi^i. \tag{47}$$

Let V denote the space of functions $f : S_n \rightarrow S_n$. If f is an element of V , then there exist a set of n functions $f_0, f_1, \dots, f_{n-1}$ mapping $\mathbf{C}^n$ into $\mathbf{C}$ such that $f = \sum_{l=0}^{n-1} f_l \pi^l$ (like (33)). Let us switch the l and the i in the right-hand side of (47). Then let ψ be the function $V \rightarrow V$ defined by

$$\psi \left(\sum_{l=0}^{n-1} f_l \pi^l \right) = \sum_{l=0}^{n-1} \left(\sum_{i=0}^{n-1} R_{l+i}(f_i) \right) \pi^l. \tag{48}$$

Theorem 12. From (26), (27), and (28), we can show that ψ is a linear involution on V .

Proof. From (26), (27), and (28), we get

$$\begin{aligned}\psi\left(\psi\left(\sum_{l=0}^{n-1}f_l\pi^l\right)\right) &= \sum_{l=0}^{n-1}\left\{\sum_{i=0}^{n-1}R_{l+i}\left[\sum_{k=0}^{n-1}R_{i+k}(f_k)\right]\right\}\pi^l \\ &= \sum_{l=0}^{n-1}\left[\sum_{i=0}^{n-1}R_{l+i}(f_l)\right]\pi^l \\ &= \sum_{l=0}^{n-1}f_l\pi^l.\end{aligned}\quad (49)$$

That is, $\psi^2 = \psi^0$ (the identity function on V). Then, ψ is a linear involution on V . $\square$

Consider the set $W = \{\alpha\psi^0 + \beta\psi \mid \alpha, \beta \in \mathbb{C}\}$, that is, linear combinations over $\mathbb{C}$ of ψ^0 and ψ (since $\psi^2 = \psi^0$). Then W is a 2×2 complex circulant algebra; $(\psi^0 + \psi)/2$ and $(\psi^0 - \psi)/2$ are idempotent elements of W ; that is, they are projections on V . If f is in V , then $\psi(f) = f$ if and only if $f \in \text{Ran}(\psi^0 + \psi)/2$, and $\psi(f) = -f$ if and only if $f \in \text{Ran}(\psi^0 - \psi)/2$. Also, $V = (\text{Ran}(\psi^0 + \psi)/2) \oplus (\text{Ran}(\psi^0 - \psi)/2)$ (a direct sum).

Example 13. If $n = 2$, then $\pi^2 = -I$. Let f and g be two functions $\mathbb{C}^2 \rightarrow \mathbb{C}$. Then

$$\begin{aligned}\psi(I f(c_0, c_1) + \pi g(c_0, c_1)) &= \frac{I}{2} [f(c_0, c_1) - if(ic_0, -ic_1) + g(c_0, c_1) + ig(ic_0, -ic_1)] \\ &\quad + \frac{\pi}{2} [f(c_0, c_1) + if(ic_0, -ic_1) \\ &\quad + g(c_0, c_1) - g(-c_0, -c_1)].\end{aligned}\quad (50)$$

Note that, if f_i is a function $\mathbb{C}^n \rightarrow \mathbb{C}$ for each i , we have by (48) that

$$\psi(f_i\pi^i) = \sum_{l=0}^{n-1} R_{l+i}(f_i)\pi^l. \quad (51)$$

In the same way, (48) implies that

$$\psi[R_{l+i}(f_l)\pi^l] = R_{l+i}(f_l)\pi^i, \quad (52)$$

where l and i vary from 0 to $n-1$ and $l+i$ is taken modulo n . Since $\psi(f) = f$ if and only if $f \in \text{Ran}(\psi^0 + \psi)/2$, the function

$$\begin{aligned}\left(\frac{1}{2}\right)(\psi^0 + \psi)[R_{l+i}(f_l)\pi^l] \\ = \left(\frac{1}{2}\right)R_{l+i}(f_l)(\pi^l + \pi^i)\end{aligned}\quad (53)$$

is a fixed point of ψ .

6. Conclusion

We prove that the set of skew-circulants with complex entries has an idempotent basis. This paper displays algebras of operators which are isomorphic to the algebra of $n \times n$ complex skew-circulant matrices. In [19], a new fast algorithm for optimal design of block digital filters (BDFs) is proposed based on skew circulant matrix. The reason why we focus our attention on skew-circulant operator is to explore the application of skew-circulant in the related field. On the basis of existing application situation [2–8], we will exploit solving ordinary, partial, and delay differential equations based on skew circulant operator.

Conflict of Interests

The authors declare that there is no conflict of interests regarding the publication of this paper.
