This paper is concerned with sampled-data controller design for singular systems with time delay. It is assumed that the sampling periods are arbitrarily varying but bounded. A time-dependent Lyapunov function is proposed, which is positive definite at sampling times but not necessarily positive definite inside the sampling intervals. Combining input delay approach with Lyapunov method, sufficient conditions are derived which guarantee that the singular system is regular, impulse free, and exponentially stable. Then, the existence conditions of desired sampled-data controller can be obtained, which are formulated in terms of strict linear matrix inequality. Finally, numerical examples are given to demonstrate the effectiveness and the benefits of the proposed method.

1. Introduction

In the last decade, considerable attention has been devoted to sampled-data control systems, because modern control systems usually employ digital technology for controller implementation [1–8]. The systems can adopt a digital computer to sample and quantize a continuous-time measurement signal to produce a discrete-time control input signal, which will be converted back into a continuous-time control input signal using a zero-order hold (ZOH) [9]. Recently, three main approaches have been adopted to analyze the sampled-data systems. The first one is based on discrete-time models [9]. The second one is based on the representation of the sampled-data system in the form of impulsive model. The impulsive model approach was applied to sampled-data stabilization of linear uncertain systems in the case of constant sampling, where a piecewise linear in time Lyapunov function was suggested [10]. The third one is the input delay approach [11], where the system is modeled as a continuous-time system with the delayed control input, and it is popular and has been widely adopted in sampled-data systems [12–15]. In [16], a novel time dependent Lyapunov functional-based technique for sampled-data control has been introduced in the framework of the input delay approach. The most significant advantage of the method is that the sawtooth evolution of the time-varying delay induced by sample and hold is used. Thus, Recently, the time-dependent Lyapunov functional method has been applied to all sorts of sampled-data systems, and some useful results have been obtained (see, e.g., [17–24] and the references therein).

On the other hand, singular systems, also referred to as descriptor systems, generalized state-space systems, differential-algebraic systems, or semistate systems, provide convenient and natural representations in the description of economic systems, power systems, and circuits systems [25–30], and it have been extensively studied in the past few years due to the fact that singular systems better describe physical systems than state-space ones. Apparently, in nowadays digitalized world, it is of both theoretical significance and practical importance to analyze how a digitalized control signal would influence the singular systems. In other words, there is a vital need to investigate the sampled-data control for singular systems. Unfortunately, although sampled-data control technologies have been developed relatively well in control theory, the particular sampled-data control for singular systems has so far received very little attention mainly due to the mathematical complexity. Indeed, the essential difficulties would be (1) how to deal with the obtained results to guarantee the considered singular systems not only to be stable but also to be regular and impulse free in order to ensure the existence, uniqueness, and absence of impulses of a solution to a given system, (2) how to fully adopt the available
information about the actual sampling pattern, and (3) how
to actually design a set of easy-to-implement sampled-data
controllers in order to guarantee that the singular systems
are exponentially stable. It is, therefore, the main aim of
this paper to challenge the sampled-data control for singular
systems by overcoming the aforementioned three major
difficulties.

This paper is concerned with the sampled-data control
of singular systems with time delays which are important
sources of oscillation, divergence, and instability in sys-
tems, and thus time-delay systems have been widely studied
recently [31, 32]. In terms of LMI approach, stability condi-
tions, and thus time-delay systems have been widely studied
sources of oscillation, divergence, and instability in sys-
tems by overcoming the aforementioned three major
difficulties.

2 Abstract and Applied Analysis

2. Problem Formulation

Consider the following sampled-data control of singular system:

\[
E\dot{x}(t) = Ax(t) + A_d x(t-d) + u(t), \quad t > 0
\]

\[
x(t) = \phi(t), \quad t \in [-d, 0],
\]  

(1)

where \(x(t) \in \mathbb{R}^n\) is the state vector, \(u(t) \in \mathbb{R}^n\) is the control
input, and the initial condition, \(\phi(t)\), is a continuous vector
valued initial function of \(t \in [-d, 0]\). \(E, A, A_d\) are known
matrices of appropriate dimensions, where \(E \in \mathbb{R}^{n \times m}\) may
be singular, and we assume that \(\text{rank } E = r \leq n \cdot d\) is a given
time delay.

In this paper, it is assumed that we only have the mea-
surement \(x(t_k)\) at the sampling instant \(t_k\); that is, only discrete
measurements of \(x(t)\) are available for control purposes, and
the control signal is assumed to be generated by using a zero-
order-hold (ZOH) function with a sequence of hold times:

\[
0 = t_0 < t_1 < \cdots < t_k < \cdots \lim_{k \to \infty} t_k = +\infty.
\]  

(2)

Also, the sampling is not required to be periodic, and
the only assumption is that the distance between any two
consecutive sampling instants is less than a given bound. It
is assumed that

\[
t_{k+1} - t_k = h_k \leq h
\]  

(3)

to all \(k \geq 0\), where \(h > 0\) represents the upper bound of the
sampling periods. Then, for system (1), we consider a state-
feedback control law of the form

\[
u(t) = K x(t_k), \quad t_k \leq t < t_{k+1},
\]  

(4)

where \(K\) is the local gain matrix of the state feedback
to controller to be determined.

By substituting (4) into (1), we obtain

\[
E \dot{x}(t) = A x(t) + A_d x(t - d) + K x(t_k), \quad t > 0
\]

\[
x(t) = \phi(t), \quad t \in [-d, 0].
\]  

(5)

Throughout this paper, we will use the following concepts.

Definition 1.

(1) The pair \((E, A)\) is said to be regular if \(\text{det}(sE - A)\) is

not identically zero.

(2) The pair \((E, A)\) is said to be impulse free if \(\text{deg}(\text{det}(sE - A)) = \text{rank } E\).

Definition 2 (see [33]).

(1) The sampled-data control of singular system (5) is
said to be regular and impulse free if the pair \((E, A)\) is

regular and free.

(2) The sampled-data control of singular system (5) is

said to be exponentially stable, if there exist scalars

\(\alpha > 0\) and \(\beta > 0\) such that

\[
\|E x(t)\| \leq e^{\alpha t} \|x_0\|, \quad \forall t \geq 0,
\]  

(6)

where \(\|x_0\| = \sup_{-d \leq \theta \leq 0} \|x(\theta)\|, \|E \dot{x}(\theta)\|\).

(3) The sampled-data control of singular system (5) is

said to be exponentially admissible, if it is regular, 

impulse free, and exponentially stable.

Lemma 3. Given singular system (5), the following inequality
holds:

\[
\|E x(t)\|^2 \leq \theta_1 \|x(t_k)\|^2 + \theta_2 \int_{t_k-d}^{t_k} \|x(\alpha)\|^2 d\alpha, \quad t_k \leq t < t_{k+1},
\]  

(7)

where \(\theta_1 = 4\|E\|^2 + \|K\|^2 h e^{4\|A_d\|^2 + \|A_d\|^2 t}, \theta_2 =
4\|A_d\|^2 e^{4\|A_d\|^2 + \|A_d\|^2 t}\).

Proof. For any \(t \in [t_k, t_{k+1})\), it follows from (5) that

\[
\|E x(t)\| \leq \|E x(t_k)\| + \left| \int_{t_k}^{t} A_d x(\alpha - d) d\alpha \right|
\]  

(8)

+ \left| \int_{t_k}^{t} A_d x(\alpha - d) d\alpha \right|.
Applying the Cauchy-Schwarz inequality, we find from (8) that
\[
\|E(x(t))\|^2 \leq 4 \|E(x(t_k))\|^2 + 4 \int_{t_k}^{t} \|A(x(\alpha))\|^2 d\alpha + 4 \int_{t_k}^{t} \|K(x(t_k))\|^2 d\alpha.
\]
(9)

Using the Cauchy-Schwarz inequality again, we obtain from (9) that
\[
\|E(x(t))\|^2 \leq 4 \|E(x(t_k))\|^2 + 4 \int_{t_k}^{t} \|A(x(\alpha))\|^2 d\alpha + 4 \int_{t_k}^{t} \|K(x(t_k))\|^2 d\alpha
\]
+ \[4 \|K\|^2 \int_{t_k}^{t} \|x(t_k)\|^2 d\alpha + 4 \|A\|^2 \int_{t_k}^{t} \|x(\alpha)\|^2 d\alpha \]
\[+ 4 \|A_d\|^2 \int_{t_k}^{t} \|x(\alpha-d)\|^2 d\alpha.\]
(10)

Applying the Gronwall-Bellman Lemma to (10), we can obtain (7) immediately. This completes the proof. \[\square\]

3. Main Results

In this section, the exponential stability of sampled-data control for singular system (5) is first investigated based on the time-dependent Lyapunov functional approach, and sufficient condition is derived to guarantee the system stability and synthesize the sampled-data controllers in the form of (4).

**Theorem 4.** Given scale \(\alpha > 0\), the sampled-data control for singular system (5) is exponentially stable if there exist symmetric positive-definite matrices \(P, F, Q, Z, U, [R_1, R_2] > 0, X_j, j = 1, 2, 3, 4, 5, F_1, L, H = [H_1, H_2, H_3, H_4]\), such that
\[
E^T F = F^T E \geq 0, \quad (11)
\]

\[
\begin{pmatrix}
\Xi_{11} + \Theta_{11} (\tilde{h}) & \Xi_{12} + \Theta_{12} (\tilde{h}) & \Xi_{13} + \Theta_{13} (\tilde{h}) & \Xi_{14} + \Theta_{14} (\tilde{h}) & \Xi_{15} \\
* & \Xi_{22} + \tilde{h} U & \Xi_{23} + \Theta_{23} (\tilde{h}) & \tilde{h} E^T X_3 E & F_1 A_d \\
* & * & \Xi_{33} + \Theta_{33} (\tilde{h}) & \Xi_{34} + 2 \alpha \tilde{h} X_4 & 0 \\
* & * & * & \Xi_{44} + \Theta_{44} (\tilde{h}) & 0 \\
* & * & * & * & \Xi_{55}
\end{pmatrix} < 0, \quad \tilde{h} \in [0, h], \quad (12)
\]

\[
\begin{pmatrix}
\Xi_{11} & \Xi_{12} & \Xi_{13} & \Xi_{14} & \Xi_{15} & \sqrt{\tilde{h}} E^T H_1^T E \\
* & \Xi_{22} & \Xi_{23} & 0 & F_1 A_d & \sqrt{\tilde{h}} E^T H_2^T E \\
* & * & \Xi_{33} - e^{-2 \alpha \tilde{h}} R_3 & \Xi_{34} & 0 & \sqrt{\tilde{h}} E^T H_3^T E \\
* & * & * & \Xi_{44} & 0 & \sqrt{\tilde{h}} E^T H_4^T E \\
* & * & * & * & \Xi_{55} & 0 \\
* & * & * & * & * & -e^{-2 \alpha \tilde{h}} E^T U E
\end{pmatrix} < 0, \quad (13)
\]
where

\[
\Xi_{11} = 2\alpha E^T P E + Q - \frac{E^T X_1 + X_1^T E}{2} - \frac{e^{-2\alpha d}}{d} E^T Z E + E^T \left( H_1 + H_1^T \right) E + F^T A + A^T F, \\
\Xi_{12} = E^T P + E^T H_2 E - F^T + A^T F_1, \\
\Xi_{13} = E^T \left( X_1 - X_2 \right) E + E^T \left( H_3 - H_3^T \right) E + F^T K, \\
\Xi_{14} = -E^T X_3 E + E^T H_4 E, \\
\Xi_{15} = \frac{e^{-2\alpha d}}{d} E^T Z E + F^T A_d, \\
\Xi_{22} = d Z - F_1 - F_1^T, \\
\Xi_{23} = -E^T H_2 E - F_1^T K, \\
\Xi_{33} = E^T \left( X_2 + X_2^T - \frac{X_1 + X_1^T}{2} \right) E - E^T \left( H_3 + H_3^T \right) E, \\
\Xi_{34} = -E^T X_4 E - e^{-2\alpha R_1} - E^T H_4 E^T, \\
\Xi_{44} = -E^T X_5 + \frac{X_5^T E}{2} - e^{-2\alpha R_1} R_1, \\
\Xi_{55} = -\frac{e^{-2\alpha d}}{d} Q - \frac{e^{-2\alpha d}}{d} E^T Z E, \\
\Theta_{11} \left( \bar{H} \right) = a_\phi E^T \left( X_1 + X_1^T \right) E + \bar{h} E^T \left( X_3 + X_3^T \right) E + \bar{h} R_1, \\
\Theta_{12} \left( \bar{H} \right) = \bar{h} E^T \frac{X_1 + X_1^T}{2} E, \\
\Theta_{13} \left( \bar{H} \right) = 2a_\phi E^T \left( -X_1 + X_2 \right) E + \bar{h} E^T X_3 E + \bar{h} R_2, \\
\Theta_{14} \left( \bar{H} \right) = 2a_\phi E^T X_3 E + \bar{h} E^T \frac{X_4 + X_4^T}{2} E, \\
\Theta_{23} \left( \bar{H} \right) = \bar{h} E^T \left( -X_1 + X_2 \right) E, \\
\Theta_{33} \left( \bar{H} \right) = 2a_\phi E^T \left( -X_3 - X_3^T + \frac{X_1 + X_1^T}{2} \right) E + \bar{h} R_3, \\
\Theta_{44} \left( \bar{H} \right) = a_\phi E^T \left( X_5 + X_5^T \right) E.
\]

(14)

Proof. Since rank \( E = r \leq n \), there exist nonsingular matrices \( \overline{G} \) and \( \overline{H} \) such that

\[
E = \overline{G} \overline{E} \overline{H} = \begin{bmatrix} I_r & 0 \\ 0 & 0 \end{bmatrix}.
\]

(15)

Similar to (15), we define

\[
\overline{A} = \overline{G} \overline{A} \overline{H} = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}, \quad \overline{F} = \overline{G} \overline{F} \overline{H} = \begin{bmatrix} F_{11} & F_{12} \\ F_{21} & F_{22} \end{bmatrix}.
\]

(16)

From (11), we have \( \overline{F} = \begin{bmatrix} F_{11} & 0 \\ F_{21} & F_{22} \end{bmatrix} \), and \( F_{11} = F_{11}^T > 0 \).

Premultiplying and postmultiplying \( \Xi_{11} < 0 \) by \( \overline{H}^T \) and \( \overline{H} \), respectively, we have \( A_{22}^T F_{22} + F_{22}^T A_{22} < 0 \), which implies that \( A_{22} \) is nonsingular and the pair \( (E, A) \) is regular and impulse free. Then, by Definition 2, the sampled-data control for singular system (5) is regular and impulse free.

Next, we will show the exponential stability of system (5). Consider the following Lyapunov functional of sampled-data control for singular system (5):

\[
V(t) = \sum_{i=1}^{6} V_i(t), \quad t \in [t_k, t_{k+1}),
\]

(17)

\[
V_1(t) = e^{2\alpha t} x(t)^T E^T P E x(t),
\]

\[
V_2(t) = \int_{t-d}^{t} e^{2\alpha s} x(s)^T Q x(s) ds,
\]

\[
V_3(t) = \int_{t-d}^{t} e^{2\alpha s} x(s)^T E^T Z E x(s) ds d\theta,
\]

\[
V_4(t) = (t_{k+1} - t) \int_{t_k}^{t} e^{2\alpha s} x(s)^T E^T U E x(s) ds,
\]

\[
V_5(t) = (t_{k+1} - t) \int_{t_k}^{t} e^{2\alpha s} x(s)^T \left[ R_1 \right] \left[ R_2 \right] x(s) ds,
\]

\[
V_6(t) = (t_{k+1} - t) e^{2\alpha t} \left[ \int_{t_k}^{t} x(s) ds \right]^T \left[ E^T \Gamma E \right] \left[ \int_{t_k}^{t} x(s) ds \right],
\]

\[
\Gamma = \begin{bmatrix} \frac{X_1 + X_1^T}{2} & X_3 & -X_1 + X_2 \\ * & X_5 + X_5^T & X_4 \\ * & * & -X_2 - X_2^T + \frac{X_1 + X_1^T}{2} \end{bmatrix}.
\]

(18)

It is noted that, similar to [16], we have

\[
\lim_{t \rightarrow t_k^-} V_j(t) = \lim_{t \rightarrow t_k^-} V_j(t_k) = 0, \quad j = 4, 5, 6.
\]

(19)

Therefore, \( V(t) \) is continuous in time since \( \lim_{t \rightarrow t_k^-} V(t) = V(t_k) \). Calculating the time derivative of \( V(t) \) along the trajectories of (5) gives the following result:

\[
\dot{V}_1(t) = 2 e^{2\alpha t} x(t)^T E^T P E \dot{x}(t) + 2ae^{2\alpha t} x(t)^T E^T P E \dot{x}(t),
\]

(20)

\[
\dot{V}_2(t) = e^{2\alpha t} x(t)^T Q x(t) - e^{2\alpha t} e^{-2\alpha d} \times x(t - d)^T Q x(t - d),
\]

(21)
\[
\dot{V}_3(t) = d e^{2\alpha t} \dot{x}(t)^T E^T Z E \dot{x}(t) \\
- \int_{t-d}^{t} e^{2\alpha s} \dot{x}(s)^T E^T Z E \dot{x}(s) \, ds \\
\leq d e^{2\alpha t} \dot{x}(t)^T E^T Z E \dot{x}(t) \\
- e^{2\alpha t} \int_{t-d}^{t} e^{-2\alpha s} \dot{x}(s)^T E^T Z E \dot{x}(s) \, ds,
\]
(22)

\[
\dot{V}_4(t) = (t_{k+1} - t) e^{2\alpha t} \dot{x}(t)^T U E \dot{x}(t) \\
- \int_{t_k}^{t} e^{2\alpha s} \dot{x}(s)^T E^T U E \dot{x}(s) \, ds \\
\leq (t_{k+1} - t) e^{2\alpha t} \dot{x}(t)^T U E \dot{x}(t) \\
- \int_{t_k}^{t} e^{2\alpha s} \dot{x}(s)^T E^T U E \dot{x}(s) \, ds
\]
(23)

\[
\dot{V}_5(t) = - \int_{t_k}^{t} e^{2\alpha t} \left[ \frac{x(s)}{x(t_k)} \right]^T \left[ R_1 \ R_2 \ R_3 \right] \left[ \frac{x(s)}{x(t_k)} \right] \, ds \\
\quad + (t_{k+1} - t) e^{2\alpha t} \left[ \frac{x(t)}{x(t_k)} \right]^T \left[ R_1 \ R_2 \ R_3 \right] \left[ \frac{x(t)}{x(t_k)} \right] \\
\leq - \int_{t_k}^{t} e^{2\alpha t} \left[ \frac{x(s)}{x(t_k)} \right]^T \left[ R_1 \ R_2 \ R_3 \right] \left[ \frac{x(s)}{x(t_k)} \right] \, ds \\
\quad + (t_{k+1} - t) e^{2\alpha t} \left[ \frac{x(t)}{x(t_k)} \right]^T \left[ R_1 \ R_2 \ R_3 \right] \left[ \frac{x(t)}{x(t_k)} \right] \\
\leq - e^{2\alpha t} \int_{t_k}^{t} e^{-2\alpha h} \left[ \frac{x(s)}{x(t_k)} \right]^T \left[ R_1 \ R_2 \ R_3 \right] \left[ \frac{x(s)}{x(t_k)} \right] \, ds \\
\quad + (t_{k+1} - t) e^{2\alpha t} \left[ \frac{x(t)}{x(t_k)} \right]^T \left[ R_1 \ R_2 \ R_3 \right] \left[ \frac{x(t)}{x(t_k)} \right] \\
\quad = (t_{k+1} - t) e^{2\alpha t} \left[ \frac{x(t)}{x(t_k)} \right]^T \left[ R_1 \ R_2 \ R_3 \right] \left[ \frac{x(t)}{x(t_k)} \right] \\
\quad - e^{2\alpha t} \int_{t_k}^{t} e^{-2\alpha h} \left[ x(s) \right]^T R_1 x(s) \, ds \\
\quad - 2 e^{2\alpha t} x(t_k)^T e^{-2\alpha h} R_2^t \int_{t_k}^{t} x(s) \, ds \\
\quad - e^{2\alpha t} (t - t_k) x(t_k)^T e^{-2\alpha h} R_3 x(t_k),
\]
(24)

According to Jensen integral inequality [34], we have

\[
- \int_{t-d}^{t} e^{-2\alpha d} \dot{x}(s)^T E^T Z E \dot{x}(s) \, ds \\
\leq - \int_{t-d}^{t} \dot{x}(s)^T Z \, ds e^{-2\alpha d} Z \int_{t-d}^{t} \dot{x}(s) \, ds \\
= \left[ \frac{x(t)}{x(t-d)} \right]^T \left[ -\frac{e^{-2\alpha d} E^T Z E}{d} \right] \left[ -\frac{e^{-2\alpha d} E^T Z E}{d} \right] \left[ -\frac{e^{-2\alpha d} E^T Z E}{d} \right]
\]
(26)
\[-\int_{t_k}^{t} e^{-2\alpha h} x(s)^T R_1 x(s) \, ds \leq -\int_{t_k}^{t} x(s)^T ds \frac{e^{-2\alpha h}}{h} R_1 \int_{t_k}^{t} x(s) \, ds.\]  

(27)

Applying (26) and (27) to (22) and (24), respectively, we can get

\[V_3(t) \leq d e^{2\alpha t} \hat{x}(t)^T E^T Z E \hat{x}(t) + e^{2\alpha t} \begin{bmatrix} x(t) \\ x(t-d) \end{bmatrix}^T R_1 \begin{bmatrix} R_1 & R_2 \\ * & R_3 \end{bmatrix} \begin{bmatrix} x(t) \\ x(t-d) \end{bmatrix} - e^{2\alpha t} \int_{t_k}^{t} x(s)^T ds \frac{e^{-2\alpha h}}{h} R_1 \int_{t_k}^{t} x(s) \, ds - 2e^{2\alpha t} x(t_k)^T e^{-2\alpha h} R_2 \int_{t_k}^{t} x(s) \, ds - e^{2\alpha t} (t - t_k) x(t_k)^T e^{-2\alpha h} R_3 x(t_k).\]

(28)

Furthermore, based on Schur complement, it can be found that for any appropriately dimensioned matrix \(H\)

\[
\begin{bmatrix} H^T e^{2\alpha h} U^{-1} H & H^T \\ * & e^{-2\alpha h} U \end{bmatrix} \geq 0
\]

(30)

which implies

\[
\int_{t_k}^{t} \begin{bmatrix} \phi(t) \\ E \hat{x}(s) \end{bmatrix}^T \begin{bmatrix} H^T e^{2\alpha h} U^{-1} H & H^T \\ * & e^{-2\alpha h} U \end{bmatrix} \begin{bmatrix} \phi(t) \\ E \hat{x}(s) \end{bmatrix} \, ds \geq 0,
\]

(31)

where

\[
\phi(t) = \begin{bmatrix} x(t)^T \\ [E \hat{x}(t)]^T x(t_k)^T \int_{t_k}^{t} x(s)^T \, ds \end{bmatrix}^T.
\]

(32)

Applying the above inequality to (23), we obtain

\[
\dot{V}_4(t) \leq e^{2\alpha t} \left( t - t_k \right) \phi(t)^T E^T H^T e^{2\alpha h} U^{-1} H \phi(t) + 2e^{2\alpha t} \phi(t)^T E^T H^T E \hat{x}(t) - 2e^{2\alpha t} \phi(t)^T E^T H^T \hat{x}(t_k) + e^{2\alpha t} \left( t_{k+1} - t \right) \hat{x}(t)^T E^T U E \hat{x}(t).
\]

(34)

On the other hand, according to (5), for any appropriately dimensioned matrix \(F, F_1\), the following equation holds:

\[
0 = 2e^{2\alpha t} \begin{bmatrix} x(t)^T F^T + \hat{x}(t)^T E^T F_1 \end{bmatrix} \times \begin{bmatrix} -E \hat{x}(t) + A x(t) + A_\phi x(t - d) + K x(t_k) \end{bmatrix}.
\]

(35)

Then, adding the right-hand side of (35) to \(\dot{V}(t)\), we obtain from (20), (21), (25), (28), (29), and (34) that for \(t \in [t_k, t_{k+1})\)

\[
\dot{V}(t) \leq e^{2\alpha t} \chi(t)^T \begin{bmatrix} t_{k+1} - t \\ h_k \end{bmatrix} \Xi_1(h_k) + \begin{bmatrix} -t_k \Xi_2(h_k) \end{bmatrix} \chi(t),
\]

(36)

where \(\Xi_2(h_k)\) is given in (38), and

\[
\chi(t) = \begin{bmatrix} x(t)^T \\ [E \hat{x}(t)]^T x(t_k)^T \int_{t_k}^{t} x(s)^T \, ds \end{bmatrix}^T (x(t-d))^T
\]

(37)

\[
\Xi_1(h_k) = \begin{bmatrix} \Xi_{11} & \Xi_{12} & \Xi_{13} & \Xi_{14} & \Xi_{15} \\ \Xi_{21} & \Xi_{22} & \Xi_{23} & 0 & F_1 A_d \\ \Xi_{33} - e^{-2\alpha h} R_3 & \Xi_{34} & 0 \end{bmatrix}
\]

(38)

\[
\Xi_2(h_k) = \begin{bmatrix} E^T H_1^T E \\ E^T H_2^T E \\ E^T H_3^T E \end{bmatrix}
\]

It is noted that

\[
\Xi_1(h_k) = h_k \Xi_1(h) + \frac{h - h_k}{h} \Xi_1(0), \quad \Xi_2(h_k) = h_k \Xi_2(h) + \frac{h - h_k}{h} \Xi_2(0).
\]

(39)

(40)

From (12) and (13), we can find that

\[
\Xi_1(h_k) < 0, \quad \Xi_2(0) < 0.
\]

(41)
Based on Schur complement, we have from (13)
$$\overline{\xi} \mathbf{2} (h) < 0.$$  \hspace{1cm} (42)
From (40), (41), we can get that
$$\overline{\xi} \mathbf{2} (h_k) < 0.$$  \hspace{1cm} (43)
Thus, we obtain from (36), (41), and (43) that
$$\dot{V} (t) < 0, \quad t \in [t_k, t_{k+1}) .$$  \hspace{1cm} (44)
Thus, it follows that, for $t \in [t_k, t_{k+1})$,
$$V (t) \leq V (t_k) \leq V (t_{k-1}) \leq \cdots \leq V (0).$$  \hspace{1cm} (45)
Based on Lemma 3 and (45) and letting $\bar{P} = E^T PE$, we can conclude that for $t_k \leq t < t_{k+1}$
$$\| E \dot{x}(t) \|^2 + d^2 \lambda_{\text{max}} (Z) \sup_{-d \leq \theta \leq 0} \| E \dot{x}(\theta) \|^2 \leq \theta_3 \left( \sup_{-d \leq \theta \leq 0} \| x(\theta) \|, \| E \dot{x}(\theta) \| \right)^2,$$  \hspace{1cm} (47)
where
$$\theta_3 = \lambda_{\text{max}} (\bar{P}) + d \lambda_{\text{max}} (Q) + d^2 \lambda_{\text{max}} (Z).$$  \hspace{1cm} (48)
Based on (46) and (47), we can conclude that
$$\| E \dot{x}(t) \| \leq e^{\eta h} \max \left\{ \frac{\theta_1}{\lambda_{\text{min}} (\bar{P})}, \frac{\theta_2 e^{2\eta d}}{\lambda_{\text{min}} (Q)} \right\} \theta_3 e^{-\alpha t} \| x_0 \| ,$$  \hspace{1cm} (49)
Thus, according to Definition 2, the sampled-data control for singular system (5) is exponentially admissible. This completes the proof.

Remark 5. It is noted that based on the time-dependent Lyapunov functional method, three $(t_k, t_{k+1})$-dependent terms $V_k(t_k)$, $V_0(t_k)$, and $V_0(t_k)$ are introduced in the Lyapunov functional, which make good use of the available information about the actual sampling pattern. As a consequence, the proposed result has less conservatism.

Remark 6. It should be pointed out that if $R_1 = R_2 = \epsilon I$ ($\epsilon$ is a sufficiently small positive scalar) and $R_2 = X_4 = X_5 = 0$, then $V_0(t) + V_0(t) + V_0(t)$ reduces to
$$V_0(t) + (t_{k+1} - t) e^{2\alpha t} \left( \begin{array}{c} x(t_k) \\ x(t_k) \\ t_k \end{array} \right) E^T \Psi \left( \begin{array}{c} x(t_k) \\ x(t_k) \\ t_k \end{array} \right) ,$$  \hspace{1cm} (50)
where
$$\Psi = \left[ \begin{array}{ccc} \frac{X_1 + X_1}{2} & -X_1 + X_2 \\ * & -X_2 - X_2 + X_1 + \frac{X_1}{2} \end{array} \right] ,$$  \hspace{1cm} (51)
which was first proposed for linear sampled-data systems in [16]. On the other hand, in [16] the Lyapunov functional should be positive definite at the whole sampling intervals. While the Lyapunov functional (17) is positive definite only at sampling times but not necessarily positive definite inside the sampling intervals. Thus, the Lyapunov functional used in this paper is more general and desirable than the one adopted in [16].

Based on Theorem 4, we can obtain the following corollary.

Corollary 7. If (12) and (13) are feasible for $\alpha = 0$, then the system (5) is exponentially stable with a small enough decay rate.

Now, we will design the sampled-data controller (4) such that system (5) is exponentially stable. Based on Theorem 4, the sampled-data controller design method for system (5) is provided in the following theorem.
Theorem 8. Given scalars $\alpha > 0$ and $\lambda > 0$, the sampled-data control for singular system (5) is exponentially stable if there exist symmetric positive-definite matrices $P, F, Q, Z, U$, $[R_1, R_2] > 0$, $X_j$, $j = 1, 2, 3, 4, 5, L$, $H = [H_1 \ H_2 \ H_3 \ H_4]$, such that

\[
\begin{align*}
\Xi_1(\bar{h}) &= \begin{bmatrix}
\Xi_{11} + \Theta_1(\bar{h}) & \bar{z}_{12} + \Theta_2(\bar{h}) & \Xi_{13} + \Theta_3(\bar{h}) & \Xi_{14} + \Theta_4(\bar{h}) & \Xi_{15} \\
* & \Xi_{22} + \bar{z}_U & \Xi_{23} + \Theta_3(\bar{h}) & \bar{h}E^TX_3E & \lambda FA_d \\
* & * & \Xi_{33} + \Theta_3(\bar{h}) & \Xi_{34} + 2\alpha \bar{h}X_4 & 0 \\
* & * & * & \Xi_{44} + \Theta_4(\bar{h}) & 0 \\
* & * & * & * & \Xi_{55}
\end{bmatrix} < 0, \quad (52)
\end{align*}
\]

\[
\begin{align*}
\Xi_2(\bar{h}) &= \begin{bmatrix}
\Xi_{11} & \bar{z}_{12} & \Xi_{13} & \Xi_{14} & \Xi_{15} & \sqrt{\bar{h}}E^TH_1^TE \\
* & \Xi_{22} & \Xi_{23} & 0 & \lambda FA_d & \sqrt{\bar{h}}E^TH_2^TE \\
* & * & \Xi_{33} - e^{-2\alpha \bar{h}R_3} & \Xi_{34} & 0 & \sqrt{\bar{h}}E^TH_3^TE \\
* & * & * & \Xi_{44} & 0 & \sqrt{\bar{h}}E^TH_4^TE \\
* & * & * & * & \Xi_{55} & 0 \\
* & * & * & * & * & -e^{-2\alpha \bar{h}U^TE}
\end{bmatrix} < 0, \quad (53)
\end{align*}
\]

where $\Xi_{11}, \Xi_{14}, \Xi_{13}, \Xi_{33}, \Xi_{34}, \Xi_{55}, \Theta_1(\bar{h}), \Theta_2(\bar{h}), \Theta_3(\bar{h}), \Theta_4(\bar{h}), \Theta_5(\bar{h}), \Theta_6(\bar{h}), \Theta_7(\bar{h}), \Theta_8(\bar{h}), \Theta_9(\bar{h})$ are as those in Theorem 4, and

\[
\begin{align*}
\Xi_{12} &= E^TP + E^TH_2E - F^T + A^T\lambda F^T, \\
\Xi_{13} &= E^T(\bar{X}_1 - \bar{X}_2)E + E^TH_3 - H_1^TE + L, \\
\Xi_{22} &= dZ - \lambda F - \lambda L, \\
\Xi_{23} &= -E^TH_2^TE - \lambda L.
\end{align*}
\]

Then singular system (5) is exponentially stable. Furthermore, the sampled-data controller gain matrix in (5) is given by

\[
K = F^TL. \quad (55)
\]

Proof. Letting $F_1 = \lambda F$, and $F^TK = L$, we can get from (12)-(13) that (52)-(53) hold. This completes the proof. \(\square\)

Remark 9. It should be mentioned that the problem of sampled-data exponential stability of singular systems with time constant delays and uncertain sampling is solved in Theorem 8, and sufficient conditions of the existence of the desired sampled-data controllers are also given, which are formulated by LMIs and can readily be solved by standard numerical software.

Based on Theorem 8, we can obtain the following corollary.

| Table 1: Maximum values of the upper bound $h$ for different $\alpha$. |
|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|
| $\alpha$ | 0.1 | 0.2 | 0.3 | 0.4 | 0.5 |
| $h$ | 0.3450 | 0.3150 | 0.2760 | 0.2390 | 0.2080 |

Corollary 10. If (12), (13) and (52), (53) are feasible for $\alpha = 0$, then system (5) is exponentially stable with a small enough decay rate, and the desired state feedback controller gains are given in (55).

4. Numerical Examples

In this section, two illustrative examples will be provided to demonstrate the validity and reduced conservatism of the proposed approaches.

Example 1. Consider the singular system with sampled-data control in (5). The system parameters are described as follows:

\[
A = \begin{bmatrix}
-2.5714 & 9 & 0 \\
1 & -1 & 1 \\
0 & 13.95 & 0
\end{bmatrix}, \quad \begin{bmatrix}
A_d \\
-0.1 & 0 & 0 \\
-0.1 & 0 & 0 \\
0.2 & -0.1 & 0
\end{bmatrix}, \quad E = \begin{bmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 0
\end{bmatrix}.
\]

Applying Theorem 4, as shown in Table 1, we can obtain the different maximum values of the upper bound $h$ for
different $\alpha$. From Table 1, we can find the influence of the choice of $\alpha$ on the value of the upper bound $h$. To be specific, a larger value of $\alpha$ corresponds to a smaller value of the upper bound $h$.

Next, we will design the sampled-data controller (4) such that system (5) is exponentially stable. Choosing $\alpha = 0.4$ and $h = 0.2390$, and using the MATLAB LMI Toolbox to solve the LMIs (12) and (13), we can get the following gain matrix in

$$K = \begin{bmatrix} -0.1937 & -0.2703 & -0.1003 \\ -3.4469 & -4.8445 & -0.0004 \\ 1.6194 & 2.2752 & 0.0011 \end{bmatrix}. \tag{57}$$

That is, there exists a sampled-data controller such that system (5) is exponentially stable for any sampling period $h_k \leq 0.2390$.

For the case of constant sampling period, based on Theorem 1 of [35], the maximum sampling period $h$ is 0.0158. While based on Corollary 10 with $\alpha = 0$, the largest sampling period $h$ ensuring the stability of system (9) is 0.0389, which is 146.2% larger than that of [35]. Thus, our proposed approach is able to achieve less conservative results and essentially improves the existing one.

Example 2. Consider the singular system with sampled-data control in (5) with the following parameters:

$$A = \begin{bmatrix} -0.6 & 0.54 \\ -0.6 & 0.12 \end{bmatrix},$$

$$A_d = \begin{bmatrix} -0.5 & 0.4 \\ 0.5 & -0.1 \end{bmatrix}, \quad E = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}. \tag{58}$$

In this example, we choose $\lambda = 0.3$.

For different time-delay $d$, the influence of the choice of the upper bound $h$ on the value of $\alpha$ can be seen in Figure 1. From Figure 1, it is clear that when time-delay $d$ is fixed, for a larger upper bound $h$, the value of $\alpha$ is usually smaller, and when $h$ is fixed, for a larger $d$, the value of $\alpha$ is usually larger.

Using Theorem 8 with $\alpha = 0.06$ given in this paper, the maximum value of the upper bound $h$ that system (5) is exponentially stable is 0.3029, and the corresponding gain matrix is

$$K = \begin{bmatrix} -3.9755 & 0.0646 \\ 2.1741 & -0.0142 \end{bmatrix}. \tag{59}$$

Under the above gain matrix, the response curves of system (5) are exhibited in Figure 2, which shows that the states are tending to zero; that is, singular system (5) can be stabilized by the proposed sampled-data controller.

5. Conclusion

In this paper, a sampled-data control approach was proposed for the singular systems with time delays. A time-dependent Lyapunov functional was introduced for the systems, which was positive definite at sampling times but not necessarily positive definite inside the sampling intervals. By the usage of the Lyapunov approach, sufficient condition was proposed to ensure the exponential stability of the singular systems, which can significantly reduce the conservatism. The available information about the actual sampling pattern was fully used. Based on the stability criterion, the desired sampled-data controller has also been designed. Finally, two illustrative examples have been presented to show the effectiveness and potential of the proposed new design techniques.

Conflict of Interests

The authors declare that there is no conflict of interests regarding the publication of this paper.
