1. Introduction

Assume that $H$ is a Hilbert space with inner product $\langle \cdot, \cdot \rangle$ and norm $\| \cdot \|$ induced by its inner product. Let $C$ be a nonempty, closed, and convex subset of $H$. Recall that the projection from $H$ onto $C$, denoted by $\text{Proj}_C$, assigns, to each $x \in H$, the unique point $\text{Proj}_C x \in C$ with the property

$$\| x - \text{Proj}_C x \| = \inf \{ \| x - y \| : y \in C \}.$$  \hfill (1)

Below we introduce some nonlinear operators. Let $T, A: H \to H$ be nonlinear operators.

(i) $T$ is $L$-Lipschitzian if $\| Tx - Ty \| \leq L \| x - y \|$, for all $x, y \in H$, where $L \geq 0$ is a constant.

In particular, if $L \in [0, 1)$, then $T$ is called a contraction on $H$; if $L = 1$, then $T$ is called a nonexpansive mapping on $H$. We know that the projection is nonexpansive.

(ii) $A$ is monotone if, for all $x, y \in H$,

$$\langle x - y, Ax - Ay \rangle \geq 0.$$  \hfill (2)

(iii) Given number $\beta > 0$, $A$ is said to be $\beta$-strongly monotone, if

$$\langle x - y, Ax - Ay \rangle \geq \beta \| x - y \|^2, \quad x, y \in H.$$  \hfill (3)

(iv) Given number $\nu > 0$, $A$ is said to be $\nu$-inverse strongly monotone ($\nu$-ism) if

$$\langle x - y, Ax - Ay \rangle \geq \nu \| Ax - Ay \|^2, \quad x, y \in H.$$  \hfill (4)

If $T$ is nonexpansive, then $I - T$ is monotone.

We know that the gradient-projection algorithm can be used to solve the constrained convex minimization problem. Let us recall the concrete analysis below. Consider the following constrained convex minimization problem:

$$\min_{x \in C} f(x),$$  \hfill (5)

where $f: C \to \mathbb{R}$ is a real-valued function. Assume that $f$ is Fréchet differentiable; define a sequence $\{x_n\}$ by

$$x_{n+1} = \text{Proj}_C (I - \gamma \nabla f) (x_n), \quad n \geq 0,$$  \hfill (6)

where the initial guess is taken from $C$ and the parameter $\gamma$ is a real number which satisfies certain conditions. The convergence of algorithm (6) depends on the property of $\nabla f$. In fact, if $\nabla f$ is only inverse strongly monotone, then algorithm (6) can converge weakly to a solution of the minimization problem (5). In 2011, Xu [1] provided an alternative averaged mapping approach to the gradient-projection...
algorithm; he also constructed a counterexample to prove that algorithm (6) has weak convergence only, in infinite-dimensional space. He also provided two modifications to ensure that the gradient-projection algorithms can converge strongly to a solution of (5). More investigations about the gradient-projection algorithm and its important role in solving the constrained convex minimization problem can be seen in [2–11]. Recently, the method has also been applied to solve the split feasibility problems which find application in image reconstruction and the intensity modulated radiation therapy (see [12–17]). However, sometimes the minimization problem has more than one solution, so regularization is needed.

Consider the regularized minimization problem

\[ \min_{x \in C} f_a (x) := f (x) + \frac{\alpha}{2} \|x\|^2; \]  

(7)

where \( \alpha > 0 \) is the regularization parameter, and \( f \) is Fréchet differentiable and the gradient \( \nabla f \) is \((1/L)\)-sm.

On the gradient-projection method based on the regularization, we have weak convergence result as follows: define a sequence by

\[ x_{n+1} := \text{Proj}_C \left( I - s_n \nabla f_a \right) (x_n), \quad n \geq 0, \]  

(8)

where \( \alpha > 0 \), \( 0 < \lambda < 2/L \), and \( \sum_{n=1}^{\infty} \alpha_n < \infty \). Then the sequence generated by (8) converges weakly to a minimizer of (5) in the setting of infinite-dimensional space (see [17]).

On the other hand, Tian [18] proposed the following iterative method:

\[ x_{n+1} := s_n \alpha \sqrt{\lambda} \left( x_n \right) + (I - s_n \mu F) T x_n, \]  

(9)

where \( T \) is a nonexpansive mapping on \( H \) with a fixed point, \( h \) is a contraction on \( H \) with coefficient \( 0 < \alpha < 1 \), and \( F : H \rightarrow H \) is a \( k \)-Lipschitzian and \( \eta \)-strongly monotone operator with \( k, \eta > 0 \). Letting \( 0 < \mu < 2\eta/k^2 \), \( 0 < \lambda < \mu(\eta - \mu k^2/2)/\rho = \tau/\rho \), he proved that the sequence \( \{x_n\} \) generated by (9) can converge strongly to a fixed point \( \bar{x} \in \text{Fix}(T) \), which solves the variational inequality \((\langle \lambda h - \mu F \rangle\bar{x}, x - \bar{x}) \leq 0, x \in \text{Fix}(T)\).

Combining the idea of regularization with Tian’s iterative scheme, in this paper, we will construct a new algorithm. The algorithm can not only find the minimum-solution of the constrained convex minimization problem by a single step but also ensure the strong convergence. In fact, the sequence generated by the constructed algorithm can converge strongly to a minimizer of the constrained convex minimization problem. The obtained point is also a solution of a certain variational inequality. Then we also apply the constructed algorithm to solve a split feasibility problem.

2. Preliminaries

**Lemma 1** (see [18]). Let \( C \) be a nonempty, closed, convex subset of a real Hilbert space \( H \). Let \( h : C \rightarrow C \) be a contraction with coefficient \( 0 < \rho < 1 \) and let \( F : C \rightarrow C \) be \( k \)-Lipschitzian and \( \eta \)-strongly monotone with \( k, \eta > 0 \). Then, for \( 0 < \lambda < \mu/\rho \),

\[ \langle x - y, (\mu F - \lambda h) x - (\mu F - \lambda h) y \rangle \geq (\mu \eta - \lambda \rho) \| x - y \|^2, \]

\[ \forall x, y \in C. \]  

(10)

**Lemma 2** (see [19]). Let \( C \) be a closed and convex subset of a Hilbert space \( H \) and let \( T : C \rightarrow C \) be a nonexpansive mapping with \( \text{Fix}(T) \neq \emptyset \). If \( \{x_n^\infty \} \) is a sequence in \( C \) weakly converging to \( x \) and if \( (I - T)_{n=1}^\infty \) converges strongly to \( y \), then \((I - T)x = y\).

**Lemma 3** (see [20]). Let \( C \) be a closed and convex subset of a Hilbert space \( H \). Given \( x \in H \) and \( y \in C \), then \( y = \text{Proj}_C x \) if and only if there holds the inequality

\[ \langle x - y, y - z \rangle \geq 0, \quad \forall z \in C. \]  

(11)

**Lemma 4** (see [1]). Assume that \( \{a_n\}_{n=0}^\infty \) is a sequence of nonnegative real numbers such that

\[ a_n \leq (1 - \gamma_n) a_{n+1} + \gamma_n \beta_n + \beta_n, \quad n \geq 0, \]  

(12)

where \( \{\gamma_n\}_{n=0}^\infty \) and \( \{\beta_n\}_{n=0}^\infty \) are sequences in \( (0, 1) \) and \( \{\delta_n\}_{n=0}^\infty \) is a sequence in \( \mathbb{R} \) such that

(i) \( \sum_{n=0}^\infty \gamma_n = \infty \);  

(ii) either \( \limsup_{n \rightarrow \infty} \delta_n \leq 0 \) or \( \sum_{n=0}^\infty \gamma_n |\delta_n| < \infty \);  

(iii) \( \sum_{n=0}^\infty \beta_n < \infty \).

Then \( \lim_{n \rightarrow \infty} a_n = 0 \).

We will use the following notation:

(i) \( \rightarrow \) for weak convergence and \( \rightarrow \) for strong convergence.

3. Main Results

Assume that \( H \) is a Hilbert space with inner product \( \langle \cdot, \cdot \rangle \) and norm \( \| \cdot \| \) induced by its inner product. Let \( C \) be a nonempty, closed, and convex subset of \( H \). Assume that the minimization problem (5) is consistent and its solution set is denoted by \( S \).

Rewrite the regularized constrained convex minimization problem:

\[ \min_{x \in C} f_a (x) := f (x) + \frac{\alpha}{2} \|x\|^2. \]  

(13)

Recall that \( h \) is a \( p \)-contraction on \( C \) with \( 0 < p < 1 \), and \( F \) is \( k \)-Lipschitzian and \( \eta \)-strongly monotone on \( C \) with \( k, \eta > 0 \). Given \( t \in (0, 1) \), assume that \( \alpha_t \) is continuous with respect to \( t \) and that \( \alpha_t = o(t) \) \((t \rightarrow 0)\); then there exists a constant \( D > 0 \) such that \( |\alpha_t| \leq D \) for \( t < t_0 \). Let the gradient \( \nabla f \) be \((1/L)\)-ism. For each \( m \in (0, \min(1, 1/\tau)) \), we consider the mapping \( Y_t \) on \( C \) defined by

\[ Y_t (x) := t \lambda h (x) + (I - t u F) \text{Proj}_C \left( I - \gamma \nabla f_{\alpha_t} \right) (x), \]

\[ X_t (x) := \text{Proj}_C Y_t (x), \]  

(14)

where \( 0 < \mu < 2\eta/k^2 \), \( 0 < \lambda < \mu(\eta - \mu k^2/2)/\rho = \tau/\rho \), and \( 0 < \gamma < 2/L \).
We will use the following notation in Lemma 5, Proposition 6, and Theorem 7:
\[ T_\alpha := \text{Proj}_C \left( I - \gamma \nabla f_\alpha \right) ; \]
\[ T := \text{Proj}_C \left( I - \gamma \nabla f \right) . \]

**Lemma 5.** There exists an implicit algorithm \( \{ x_t \} \); here \( x_t \) is the fixed point of \( X_t \); that is,
\[ x_t = X_t (x_t) = \text{Proj}_C Y_t (x_t) , \]
where \( X_t, Y_t \) are defined by (14).

**Proof.** Below we will show that \( X_t \) is a contraction. Indeed, we have
\[
\left\| (I - t \mu F) T_\alpha (x) - (I - t \mu F) T_\alpha (y) \right\|^2 \\
= \left\| T_\alpha (x) - T_\alpha (y) \right\|^2 + t^2 \mu^2 \left\| F T_\alpha (x) - F T_\alpha (y) \right\|^2 \\
- 2 t \mu \left\langle T_\alpha (x) - T_\alpha (y), F T_\alpha (x) - F T_\alpha (y) \right\rangle \\
\leq \left\| T_\alpha (x) - T_\alpha (y) \right\|^2 + t^2 \mu^2 \left\| F T_\alpha (x) - F T_\alpha (y) \right\|^2 \\
- 2 t \mu \left\langle T_\alpha (x) - T_\alpha (y), F T_\alpha (x) - F T_\alpha (y) \right\rangle \\
\leq \left( 1 - \frac{t \mu (2t - t \mu^2)}{2} \right) \left\| T_\alpha (x) - T_\alpha (y) \right\|^2 \\
\leq (1 - t \tau)^2 \| x - y \|^2 .
\]

It follows easily that
\[
\left\| X_t (x) - X_t (y) \right\| \\
= \left\| \text{Proj}_C Y_t (x) - \text{Proj}_C Y_t (y) \right\| \\
\leq \left\| Y_t (x) - Y_t (y) \right\| \\
= \left\| \gamma \nabla h(x) + (I - t \mu F) T_\alpha (x) - \gamma \nabla h(y) - (I - t \mu F) T_\alpha (y) \right\| \\
\leq \left\| \gamma \nabla h(x) - \gamma \nabla h(y) \right\| \\
+ \left\| (I - t \mu F) T_\alpha (x) - (I - t \mu F) T_\alpha (y) \right\| \\
\leq (1 - t (\tau - \lambda \rho)) \| x - y \|. \tag{18}
\]

Hence \( X_t \) has a unique fixed point; we denote it by \( x_t \), which uniquely solves the fixed point equation
\[ x_t = \text{Proj}_C Y_t (x_t) ; \tag{19} \]
here \( Y_t (x_t) = t \gamma \nabla h(x_t) + (I - t \mu F) \text{Proj}_C (I - \gamma \nabla f_\alpha) (x_t) \).

**Proposition 6.** Let \( x_t \) be defined by (19):
(i) \( \{ x_t \} \) is bounded for \( t \in (0,1) \).
(ii) \( \lim_{t \to 0} \| x_t - \text{Proj}_C (I - \gamma \nabla f_\alpha) (x_t) \| = 0 \).
(iii) \( x_t \) defines a continuous curve from \( (0,1/\tau) \) into \( C \).

**Proof.** (i) For \( \bar{x} \in S \), we have
\[
\| x_t - \bar{x} \| \\
= \left\| \text{Proj}_C Y_t (x_t) - \text{Proj}_C (\bar{x}) \right\| \\
\leq \| Y_t (x_t) - \bar{x} \| \\
= \left\| t \gamma \nabla h(x_t) + (I - t \mu F) T_\alpha (x_t) - \gamma \nabla h(\bar{x}) - (I - t \mu F) T_\alpha (\bar{x}) \right\| \\
\leq \| t \gamma \nabla h(x_t) - t \gamma \nabla h(\bar{x}) \| + (I - t \mu F) T_\alpha (x_t) - (I - t \mu F) T_\alpha (\bar{x}) \\
\leq \| t \gamma \nabla h(x_t) - t \gamma \nabla h(\bar{x}) \| + t \left\| \gamma \nabla h(\bar{x}) - \mu F (\bar{x}) \right\| \\
\leq \| t \gamma \nabla h(x_t) - \gamma \nabla h(\bar{x}) \| + t \left\| \gamma \nabla h(\bar{x}) - \mu F (\bar{x}) \right\| \\
\leq (1 - t (\tau - \lambda \rho)) \| x_t - \bar{x} \| + (1 + \mu k) \gamma \nabla D (\bar{x}) \\
+ t \left\| \gamma \nabla h(\bar{x}) - \mu F (\bar{x}) \right\| .
\]

It follows that \( \| x_t - \bar{x} \| \leq \left( \| \gamma \nabla h(\bar{x}) - \mu F (\bar{x}) \| + (1 + \mu k) \gamma D (\bar{x}) \right) / (\tau - \lambda \rho) \). Hence, \( \{ x_t \} \) is bounded.
(ii) We can easily see that
\[
\| x_t - \text{Proj}_C (I - \gamma \nabla f_\alpha) (x_t) \| \\
= \left\| \text{Proj}_C Y_t (x_t) - \text{Proj}_C T_\alpha (x_t) \right\| \\
\leq \| Y_t (x_t) - T_\alpha (x_t) \| \\
= \left\| t \gamma \nabla h(x_t) + (I - t \mu F) T_\alpha (x_t) - T_\alpha (x_t) \right\| \\
= t \left\| \gamma \nabla h(x_t) - \mu F T_\alpha (x_t) \right\| \\
\leq t \left( \lambda \| h(x_t) \| + \mu \| F \text{Proj}_C (I - \gamma \nabla f_\alpha) (x_t) \| \right) . \tag{21}
\]

The boundedness of \( \{ x_t \} \) implies that \( \{ h(x_t) \} \) and \( \{ F \text{Proj}_C (I - \gamma \nabla f_\alpha) (x_t) \} \) are also bounded. Hence (ii) follows.
(iii) For \( t, t_0 \in (0,1/\tau) \), we have
\[
\| x_t - x_{t_0} \| \\
= \left\| \text{Proj}_C Y_t (x_t) - \text{Proj}_C Y_{t_0} (x_{t_0}) \right\| \\
\leq \left\| Y_t (x_t) - Y_{t_0} (x_{t_0}) \right\| \\
= \left\| t \gamma \nabla h(x_t) + (I - t \mu F) T_\alpha (x_t) - t_0 \gamma \nabla h(x_{t_0}) + (I - t_0 \mu F) T_\alpha (x_{t_0}) \right\| \\
= \left\| t \gamma \nabla h(x_t) - t_0 \gamma \nabla h(x_{t_0}) \right\| + \left\| (I - t \mu F) T_\alpha (x_t) - (I - t_0 \mu F) T_\alpha (x_{t_0}) \right\| \\
\leq \left( \lambda \| h(x_t) \| + \mu \| F \text{Proj}_C (I - \gamma \nabla f_\alpha) (x_t) \| \right) / (\tau - \lambda \rho) .
\]
\[-(I - t_0 \mu F) T_{\alpha_0} (x_{t_0}) \leq |t - t_0| \lambda \|h(x_t)\| + t_0 \lambda \|h(x_t) - h(x_{t_0})\| \]
\[+ \left\| (I - t_0 \mu F) T_{\alpha_0} (x_{t_0}) - (I - t_0 \mu F) T_{\alpha_0} (x_{t_0}) \right\| \]
\[\leq |t - t_0| \lambda \|h(x_t)\| + t_0 \lambda \rho \|x_t - x_{t_0}\| \]
\[+ \left\| (I - t_0 \mu F) T_{\alpha_0} (x_{t_0}) - (I - t_0 \mu F) T_{\alpha_0} (x_{t_0}) \right\| \]
\[\leq |t - t_0| \lambda \|h(x_t)\| + t_0 \lambda \rho \|x_t - x_{t_0}\| \]
\[+ (1 - t_0 \tau) \|x_t - x_{t_0}\| \]
\[+ \left\| (I - t_0 \mu F) T_{\alpha_0} (x_{t_0}) - (I - t_0 \mu F) T_{\alpha_0} (x_{t_0}) \right\| \]
\[\leq |t - t_0| \lambda \|h(x_t)\| + t_0 \lambda \rho \|x_t - x_{t_0}\| \]
\[+ (1 - t_0 \tau) \|x_t - x_{t_0}\| + \left\| T_{\alpha_0} (x_{t_0}) - T_{\alpha_0} (x_{t_0}) \right\| \]
\[\leq |t - t_0| \lambda \|h(x_t)\| + (1 - t_0 (\tau - \lambda \rho)) \|x_t - x_{t_0}\| \]
\[+ \left\| \alpha_0 - \alpha_t \right\| \gamma \|x_t\| + |t - t_0| \mu \|FT_{\alpha_0} (x_{t_0})\| \]
\[+ t_0 \mu k \gamma |\alpha_0 - \alpha_t| \|x_t\|. \]
(22)

Hence, \(\|x_t - x_{t_0}\| \leq (\lambda \|h(x_t)\| + \mu \|F \text{Proj}_C(I - \gamma \nabla f_{\alpha_0})(x_{t_0})\|) / t_0 (\tau - \lambda \rho) \|t - t_0\| + \left\| (1 + t_0 \mu k) \gamma \|x_t\| / t_0 (\tau - \lambda \rho) \left( |\alpha_0 - \alpha_t| \right) \right\| \). Noting that \(\alpha_0\) is continuous with respect to \(t\), we get \(x_t \to x_{t_0}\) as \(t \to t_0\), and therefore \(x_t\) is continuous.

**Theorem 7.** Let \(x_t\) be defined by (19). Then \(x_t\) converges in norm, as \(t \to 0\), to a minimizer \(x^*\) of (5), which solves the following variational inequality:
\[\langle (\mu F - \lambda h)(x^*), x - x^* \rangle \geq 0, \quad \forall x \in S. \quad (23)\]

**Proof.** It follows from Lemma 1 that the variational inequality (23) has only one solution \(x^* \in S\). To prove convergence we will use Lemma 3 in the following calculations. It holds that
\[\|x_t - \bar{x}\|^2 = \langle x_t - \bar{x}, x_t - \bar{x} \rangle \]
\[= \langle \text{Proj}_C y_t - \bar{x}, x_t - \bar{x} \rangle \]
\[= \langle \text{Proj}_C y_t - y_t + y_t - \bar{x}, x_t - \bar{x} \rangle \]
\[= \langle \text{Proj}_C y_t - y_t, \text{Proj}_C y_t - \bar{x} \rangle + \langle y_t - \bar{x}, x_t - \bar{x} \rangle \]
\[\leq \langle y_t - \bar{x}, x_t - \bar{x} \rangle \]
\[= (t \lambda h(x_t) + (1 - t \mu F) T_{\alpha_0} (x_t) - \bar{x}, x_t - \bar{x}) \]
\[= \langle t \lambda h(x_t), x_t - \bar{x} \rangle + \langle (1 - t \mu F) T_{\alpha_0} (x_t) - \bar{x}, x_t - \bar{x} \rangle \]
\[\leq (t \lambda \|h(x_t)\| + (1 - t \mu k) \|y_t\| \|x_t - \bar{x}\| / t_0 (\tau - \lambda \rho) \left( |\alpha_0 - \alpha_t| \right) \|x_t\|. \]
(24)

Hence,
\[\|x_t - \bar{x}\|^2 \leq \frac{1}{\tau - \lambda \rho} \langle \lambda h(\bar{x}) - \mu F(\bar{x}), x_t - \bar{x} \rangle \]
\[+ \frac{\alpha_t (1 + \mu k) \gamma}{t_0 (\tau - \lambda \rho)} \|x_t - \bar{x}\|. \]
(25)

Since \(x_t\) is bounded for \(t \in (0, 1)\), and \(\alpha_t = o(t) (t \to \infty)\), we see that if \(x_n\) is a sequence in \((0, 1)\) such that \(x_n \to 0\) and \(x_{t_n} \to \bar{x}\), then, by (24), \(x_{t_n} \to \bar{x}\). We may further assume that \(\alpha_{t_n} \to 0\). It turns out that
\[\|x_{t_n} - \text{Proj}_C(I - \gamma \nabla f) x_{t_n}\| \]
\[\leq \|x_{t_n} - \text{Proj}_C(I - \gamma \nabla f_{\alpha_{t_n}}) x_{t_n}\| + \|\nabla_{\alpha_{t_n}} f_{\alpha_{t_n}}\| x_{t_n}\|. \]
(26)

From the boundedness of \(\{x_t\}\) and \(\lim_{t \to 0} \|x_t - \text{Proj}_C(I - \gamma \nabla f_{\alpha_0}) x_t - \bar{x}\| = 0\), we conclude that
\[\lim_{n \to \infty} \|x_{t_n} - \text{Proj}_C(I - \gamma \nabla f) x_{t_n}\| = 0. \]
(27)

It then follows from Lemma 2 that \(\bar{x} = \text{Proj}_C(I - \gamma \nabla f) \bar{x}\). This shows that \(\bar{x} \in S\).

We next prove that \(\bar{x}\) is a solution of the variational inequality (23). Since \(\text{Proj}_C(I - \gamma \nabla f_{\alpha_0})\) is nonexpansive, we see that \(I - \text{Proj}_C(I - \gamma \nabla f_{\alpha_0})\) is monotone. By (19), we have
\[x_t = \text{Proj}_C Y_t (x_t) - Y_t (x_t) + t \lambda h(x_t) + (1 - t \mu F) T_{\alpha_0} (x_t); \]
(28)
then it follows that
\[
\lambda h(x_t) = -\frac{1}{t} [Y_t(x_t) - Y_t(x_t) + (I - t\mu F) \tau_t(x_t) - x_t], \\
(\mu F - \lambda h)(x_t) = \mu F(x_t) \\
+ \frac{1}{t} \left[ \text{Proj}_{\mathcal{C}} Y_t(x_t) - Y_t(x_t) + (I - t\mu F) \tau_t(x_t) - x_t \right], \\
\langle (\mu F - \lambda h)(x_t), x_t - x \rangle = \left\langle \mu F(x_t) + \frac{1}{t} \left[ \text{Proj}_{\mathcal{C}} Y_t(x_t) - Y_t(x_t) + (I - t\mu F) \tau_t(x_t) - x_t \right], x_t - x \right\rangle \\
= \left\langle \mu F(x_t) + \frac{1}{t} \left[ \text{Proj}_{\mathcal{C}} Y_t(x_t) - Y_t(x_t), x_t - \bar{x}_t \right] \\
+ (I - t\mu F) \tau_t(x_t) - x_t \rangle, x_t - \bar{x}_t \right\rangle \\
= \frac{1}{t} \left\langle \text{Proj}_{\mathcal{C}} Y_t(x_t) - Y_t(x_t), x_t - \bar{x}_t \right\rangle \\
+ \left\langle \mu F(x_t) + \frac{1}{t} \left[ (I - t\mu F) \tau_t(x_t) - x_t \rangle, x_t - \bar{x}_t \right\rangle \\
\leq \left\langle \mu F(x_t) + \frac{1}{t} \left[ (I - t\mu F) \tau_t(x_t) - x_t \rangle, x_t - \bar{x}_t \right\rangle \\
= \mu \left( F(x_t) - FT_{\alpha_t}(x_t), x_t - \bar{x}_t \right) \\
- \frac{1}{t} \left( (I - T_{\alpha_t})(x_t), x_t - \bar{x}_t \right) \\
= \mu \left( F(x_t) - FT_{\alpha_t}(x_t), x_t - \bar{x}_t \right) \\
- \frac{1}{t} \left( (I - T_{\alpha_t})(x_t), (I - T_{\alpha_t})(\bar{x}_t) - T_{\alpha_t}(\bar{x}_t), x_t - \bar{x}_t \right) \\
= \mu \left( F(x_t) - FT_{\alpha_t}(x_t), x_t - \bar{x}_t \right) \\
- \frac{1}{t} \left( (I - T_{\alpha_t})(x_t), (I - T_{\alpha_t})(\bar{x}_t), x_t - \bar{x}_t \right) \\
+ \frac{1}{t} \left( T_{\alpha_t}(\bar{x}_t) - T(\bar{x}_t), x_t - \bar{x}_t \right) \\
\leq \mu \left( F(x_t) - FT_{\alpha_t}(x_t), x_t - \bar{x}_t \right) \\
+ \frac{1}{t} \alpha_t \gamma \|x_t - \bar{x}_t\|.
\]

Taking the limit through \(t = t_n \to 0\) ensures that \(x_t\) is a solution of the variational inequality. This implies that \(((\mu F - \lambda h)(x_t), x_t - \bar{x}_t) \geq 0\). Therefore \(x_t = x^*\). \qed

Finally we consider the explicit version of our algorithm which is
\[
y_n = s_n \lambda h(x_n) + (I - s_n \mu F) \text{Proj}_{\mathcal{C}} (I - \gamma \nabla f_{\alpha_n})(x_n), \\
x_{n+1} = \text{Proj}_{\mathcal{C}} y_n.
\]

where the initial guess \(x_0 \in C\) and \(\{\alpha_n\}_{n=0}^{\infty}\) and \(\{s_n\}_{n=0}^{\infty} \subset (0, 1)\) are the parameter sequences satisfying certain conditions.

**Theorem 8.** Assume that the minimization problem (5) is consistent and let \(S\) denote its solution set. Let the gradient \(\nabla f\) be \((1/L)\)-ism. Let \(F : C \to C\) be \(\eta\)-strongly monotone and \(k\)-Lipschitzian and let \(h : C \to C\) be a contraction with coefficient \(0 < \mu < 2\eta/k^2\), a constant \(\lambda\) with the property \(0 < \lambda < \mu(n - \mu k^2/2)/\rho = \tau/\rho\), and a constant \(\gamma\) satisfying \(0 < \gamma < 2/L\). Let \(\{x_n\}_{n=0}^{\infty}\) be generated by the iterative algorithm (30). Assume

\[(C1) s_n \to 0; \]
\[(C2) \alpha_n = o(s_n) (s_n \to 0, n \to \infty); \]
\[(C3) \sum_{n=0}^{\infty} s_n = \infty; \]
\[(C4) \sum_{n=0}^{\infty} |s_{n+1} - s_n| < \infty; \]
\[(C5) \sum_{n=0}^{\infty} |\alpha_n - \alpha_{n+1}| < \infty. \]

Then the sequence \(\{x_n\}\) converges in norm to \(x^*\) as defined in Theorem 7.

**Proof.** We set
\[
T_{\alpha_n} := \text{Proj}_{\mathcal{C}} (I - \gamma \nabla f_{\alpha_n}); \\
T := \text{Proj}_{\mathcal{C}} (I - \gamma \nabla f). 
\]

Since \(\alpha_n = o(s_n) (s_n \to 0, n \to \infty)\), there exists \(M > 0\) such that \(\alpha_n/s_n < M\) for \(n \geq n_0\).

We observe that \(\{x_n\}\) is bounded. Indeed, taking a fixed point \(p \in S\), we get
\[
\|x_{n+1} - p\| \\
\leq \|\text{Proj}_{\mathcal{C}} y_n - \text{Proj}_{\mathcal{C}} p\| \\
\leq \|y_n - p\| \\
= \|s_n \lambda h(x_n) + (I - s_n \mu F) T_{\alpha_n}(x_n) - p\| \\
\leq \|s_n \lambda h(x_n) - s_n \lambda h(p)\| \\
+ \|(I - s_n \mu F) T_{\alpha_n}(x_n) - (I - s_n \mu F) T_{\alpha_n}(p)\| \\
+ \|(I - s_n \mu F) T_{\alpha_n}(p) - (I - s_n \mu F) T(p)\| \\
+ \|s_n \lambda h(p) - s_n \lambda F(p)\| \\
\leq s_n \lambda \rho \|x_n - p\| + (1 - s_n \tau) \|x_n - p\| \\
+ \|1 + s_n \mu k\| \gamma \alpha_n \|p\| + s_n \|\lambda h(p) - \mu F(p)\| \\
\leq (1 - s_n (\tau - \lambda \rho)) \|x_n - p\| \\
+ \|1 + \mu k\| \gamma M \|p\| + s_n \|\lambda h(p) - \mu F(p)\| \\
\leq \max \left\{ \|x_n - p\|, \frac{(1 + \mu k) \gamma M \|p\| + \|\lambda h(p) - \mu F(p)\|}{\tau - \lambda \rho} \right\}.
\]
By induction $\|x_n - p\| \leq \max\{\|x_0 - p\|, (1 + \mu k)\gamma M\|p\| + \|\lambda h(p) - \mu F(p)\|/(\tau - \rho p), n \geq 0$, then $\{x_n\}$ is bounded, so are $\{h(x_n)\}$ and $\{FProj_C(I - \gamma V f_{a_n})(x_n)\}$.

We claim that $\|x_{n+1} - x_n\| \rightarrow 0$.

Because of the boundedness of $\{x_n\}$, it can be easily seen that $\{h(x_n)\}$ and $\{FT_{a_n}(x_n)\}$ are also bounded. So we can take two constants $N, E$ such that $N \geq \lambda \|h(x_{n+1})\| + \mu \|FT_{a_n}(x_{n+1})\|$ and $E \geq (1 + \mu k)\gamma \|x_{n+1}\|$. Consider

\[
x_{n+1} - x_n = \|\text{Proj}_C y_n - \text{Proj}_C y_{n+1}\|
\leq \|y_n - y_{n+1}\|
\leq \|s_n\lambda h(x_n) + (I - s_n\mu F)T_{a_n}(x_{n+1}) - s_n\lambda h(x_n)
- (I - s_n\mu F)T_{a_n}(x_{n+1}) - s_n\lambda h(x_{n+1})
\leq \|s_n\lambda h(x_n) - s_n\lambda h(x_{n+1})
+ \|s_n\lambda h(x_{n+1}) - s_{n-1}\lambda h(x_{n+1})
+ \|T_{a_n}(x_{n+1}) - T_{a_n}(x_{n+1})
\leq \|s_n\lambda\| \|h(x_{n+1})\|
+ \|s_n\lambda\| \|h(x_{n+1})\|
\leq (1 - s_n (\tau - \lambda \rho)) \|x_{n+1} - x_n\|
\]

We finally show that

\[
\lim_{n \rightarrow \infty} \sup \langle x_n - x^*, (y - \mu F) x^* \rangle \leq 0,
\]

where $x^*$ is obtained in Theorem 7. Indeed, take a subsequence $\{x_{n_k}\}$ of $\{x_n\}$ such that

\[
\lim_{k \rightarrow \infty} \langle x_{n_k} - x^*, (y - \mu F) x^* \rangle = \lim_{k \rightarrow \infty} \langle x_{n_k} - x^*, (y - \mu F) x^* \rangle.
\]

Since the sequence $\{x_n\}$ is bounded, we may assume that $x_n \rightarrow z$; it follows from Lemma 2 and (34) that $z \in S$. Then we obtain $\lim_{k \rightarrow \infty} \langle x_{n_k} - x^*, (y - \mu F)x^* \rangle = \langle z - x^*, (y - \mu F)x^* \rangle \leq 0$. By (37) we know that $\lim_{n \rightarrow \infty} \sup \langle x_n - x^*, (y - \mu F)x^* \rangle \leq 0$.

We finally show that $x_n \rightarrow x^*$. We have, using Lemma 3,

\[
\|x_{n+1} - x^*\|^2
= \langle x_{n+1} - x^*, x_{n+1} - x^* \rangle
= \langle \text{Proj}_C y_n - y_n + y_n - x^*, x_{n+1} - x^* \rangle
= \langle \text{Proj}_C y_n - y_n, x_{n+1} - x^* \rangle + \langle y_n - x^*, x_{n+1} - x^* \rangle
\]

\[
\leq \langle y_n - x^*, x_{n+1} - x^* \rangle
= \langle s_n\lambda h(x_n) + (I - s_n\mu F)T_{a_n}(x_{n+1}) - x^*, x_{n+1} - x^* \rangle
= \langle s_n\lambda h(x_n) - s_n\lambda h(x^*), x_{n+1} - x^* \rangle
+ \langle s_n\lambda h(x^*) - s_n\mu F(x^*), x_{n+1} - x^* \rangle
\]
Abstract and Applied Analysis 7

\begin{align}
+ \langle (I - s_n \mu F) T_{\alpha_n} (x_n) - (I - s_n \mu F) T_{\alpha_n} (x^*), x_{n+1} - x^* \rangle \\
+ \langle (I - s_n \mu F) T_{\alpha_n} (x^*) - (I - s_n \mu F) (x^*), x_{n+1} - x^* \rangle \\
\leq s_n \gamma \langle x_n - x^*, x_{n+1} - x^* \rangle \\
+ s_n \langle (\lambda \mu) x^*, x_{n+1} - x^* \rangle \\
+ (1 - s_n) \langle x_n - x^*, x_{n+1} - x^* \rangle \\
+ (1 + s_n \mu k) \alpha_n \|x^*\| \|x_{n+1} - x^*\| \\
\leq \frac{1}{2} (1 - s_n (\tau - \lambda \rho)) \left( \|x_n - x^*\|^2 + \|x_{n+1} - x^*\|^2 \right) \\
+ s_n \langle (\lambda \mu) x^*, x_{n+1} - x^* \rangle \\
+ (1 + \mu k) \alpha_n \|x^*\| \|x_{n+1} - x^*\|.
\end{align}

(38)

Since \( \{x_n\} \) is bounded, we can take a constant \( L' > 0 \) such that
\[
L' \geq (1 + \mu k) \gamma \|x^*\| \|x_{n+1} - x^*\|;
\]

hence,
\[
\|x_{n+1} - x^*\|^2 \\
\leq \frac{1 - s_n (\tau - \lambda \rho)}{1 + s_n (\tau - \lambda \rho)} \|x_n - x^*\|^2 \\
+ \frac{2 s_n}{1 + s_n (\tau - \lambda \rho)} \langle (\lambda \mu) x^*, x_{n+1} - x^* \rangle \\
+ \frac{2 (1 + \mu k) \alpha_n}{1 + s_n (\tau - \lambda \rho)} \|x^*\| \|x_{n+1} - x^*\| \\
\leq (1 - s_n (\tau - \lambda \rho)) \|x_n - x^*\|^2 \\
+ \frac{s_n}{1 + s_n (\tau - \lambda \rho)} \\
\times \left[ 2 \langle (\lambda \mu) x^*, x_{n+1} - x^* \rangle + 2 \frac{\alpha_n}{s_n} \right];
\]

it then follows that
\[
\|x_{n+1} - x^*\| \leq (1 - s_n (\tau - \lambda \rho)) \|x_n - x^*\|^2 + s_n \delta_n,
\]

(41)

where \( \delta_n = (2 \langle (\lambda \mu) x^*, x_{n+1} - x^* \rangle + 2 \frac{\alpha_n}{s_n})/(1 + s_n (\tau - \lambda \rho)) \).

Since \( s_n \to 0 \) and \( \alpha_n = o(s_n) \) \( (s_n \to 0, n \to \infty) \), by (37), we get \( \lim_{n \to \infty} \sup \delta_n \leq 0 \). Applying Lemma 4 to (41) concludes that \( x_n \to x^* \) as \( n \to \infty \). \( \Box \)

4. An Application

Since the split feasibility problem (say SFP, for short) was proposed by Censor and Elfving in 1994, it has been widely used in signal processing and image reconstruction, with particular progress in intensity-modulated radiation therapy.

We know that the gradient-projection method plays an important role in solving the SFP. In this section, we provide an application of Theorem 8 to the SFP (see [21, 22]).

The SFP can mathematically be formulated as the problem of finding a point \( x \) with the property
\[
x \in C, \quad Bx \in Q, \tag{42}
\]

where \( C \) and \( Q \) are nonempty, closed, and convex subset of Hilbert spaces \( H_1 \) and \( H_2 \), respectively. \( B : H_1 \to H_2 \) is a bounded linear operator.

It is clear that \( x^* \) is a solution to the split feasibility problem if and only if \( x^* \in C \) and \( Bx^* - \text{Proj}_Q Bx^* = 0 \). We define the proximity function \( f \) by
\[
f(x) = \frac{1}{2} \|Bx - \text{Proj}_Q Bx\|^2, \tag{43}
\]

and we consider the constrained convex minimization problem
\[
\min_{x \in C} \frac{1}{2} \|Bx - \text{Proj}_Q Bx\|^2. \tag{44}
\]

Then \( x^* \) solves the split feasibility problem (42) if and only if \( x^* \) solves the minimization problem (44) with the minimal value equal to \( \gamma \). Byrne introduced the so-called CQ algorithm to solve the SFP:
\[
x_{n+1} = \text{Proj}_C \left( I - \gamma B^* (I - \text{Proj}_Q) B \right) x_n, \quad n \geq 0, \tag{45}
\]

where \( 0 < \gamma < 2/\|B\|^2 \). He obtained that the sequence \( x_n \) generated by (45) converges weakly to a solution of the SFP.

Now we consider the regularization technique; let
\[
f_\alpha(x) = \frac{1}{2} \|Bx - P_Q Bx\|^2 + \frac{\alpha}{2} \|x\|^2; \tag{46}
\]

then we establish the iterative scheme as follows:
\[
y_n = s_n \lambda h (x_n) \\
+ (1 - s_n \mu) \text{Proj}_C \left( I - \gamma (B^* (I - P_Q) B + \alpha_n I) \right) x_n, \tag{47}
\]

where \( h : C \to H \) is a contraction with the coefficient \( \rho \in (0, 1) \). Let \( F : C \to H \) be \( \eta \)-strongly monotone and \( \kappa \)-Lipschitzian.

**Theorem 9.** Assume that the split feasibility problem (42) is consistent. Let the sequence \( \{x_n\} \) be generated by (47). The \( \mu \) and \( \lambda \) are constants with the same property as in Theorem 8. Fix \( 0 < \gamma < 2/\|B\|^2 \). The sequences \( \{x_n\}_{n=1}^{\infty} \) and \( \{s_n\}_{n=1}^{\infty} \subset (0, 1) \) are the parameter sequences satisfying conditions (C3)-(C5) in Theorem 8. Then the sequence \( \{x_n\} \) generated by (47) converges strongly to the solution of split feasibility problem (42).

**Proof.** By the definition of the proximity function \( f \), we have
\[
\nabla f = B^* (I - \text{Proj}_Q B) x, \tag{48}
\]

and we show that \( \nabla f = 1/\|B\|^2 \)-ism.
Since Proj₆ is (1/2)-averaged mapping, then I - Proj₆ is 1-ism:

\[
\langle \nabla f(x) - \nabla f(y), x - y \rangle - \frac{1}{\|B\|^2} \| \nabla f(x) - \nabla f(y) \|^2
\]

\[
= \langle B^* (I - \text{Proj}_6) Bx - B^* (I - \text{Proj}_6) By, x - y \rangle
\]

\[
- \frac{1}{\|B\|^2} \| B^* (I - \text{Proj}_6) Bx - B^* (I - \text{Proj}_6) By \|^2
\]

\[
= \langle (I - \text{Proj}_6) Bx - (I - \text{Proj}_6) By, Bx - By \rangle
\]

\[
- \frac{1}{\|B\|^2} \| (I - \text{Proj}_6) Bx - (I - \text{Proj}_6) By \|^2
\]

\[
\geq \| (I - \text{Proj}_6) Bx - (I - \text{Proj}_6) By \|^2
\]

\[
- \| (I - \text{Proj}_6) Bx - (I - \text{Proj}_6) By \|^2
\]

\[
= 0.
\]

(49)

Hence, \( \langle \nabla f(x) - \nabla f(y), x - y \rangle \geq 1/\|B\|^2 \| \nabla f(x) - \nabla f(y) \|^2 \).

Let \( L = \|B\|^2 \); then the iterative scheme (47) is equivalent to

\[
x_{n+1} = \text{Proj}_C \left[ s, \lambda h(x_n) + (I - s, \mu F) \text{Proj}_C \left( I - \gamma \nabla f(x) \right) x_n \right],
\]

\( n \geq 0 \), \( (50) \)

where \( 0 < \gamma < 2/L \), and then, due to Theorem 8, we have the conclusion immediately. \( \square \)

### 5. Numerical Result

In this section, we present the following simple example to judge the numerical performance of our algorithm. We use the algorithm in Theorem 9 to illustrate its realization in solving system of linear equations.

**Example 10.** In Theorem 9, we assume that \( H_1 = H_2 = \mathbb{R} \). Take \( h = (1/2)I \), where \( I \) denotes the 3×3 identity matrix, and \( F = I \) with Lipschitz constant \( k = 1 \) and strongly monotone constant \( \eta = 1 \). Given the parameters \( s_n = 1/(n + 2), \alpha_n = 1/(n + 2)^2 \) for every \( n \geq 0 \). Fix \( \mu = 1, \lambda = 1/2, \) and \( \gamma = 1/10 \). Take

\[
B = \begin{pmatrix}
1 & 0 & 1 \\
-1 & 1 & 0 \\
1 & 2 & -3
\end{pmatrix}, \quad b = \begin{pmatrix}
5 \\
-7 \\
-17
\end{pmatrix}.
\]

\( (51) \)

The SFP can be formulated as the problem of finding a point \( x^* \) with the property

\[
x \in C, \quad Bx^* \in Q, \quad (52)
\]

where \( C = H_1, Q = \{b\} \subset H_2 \). That is, \( x^* \) is the solution of system of linear equations \( Bx = b \), and

\[
x^* = \left( \begin{array}{c}
2 \\
-5 \\
3
\end{array} \right).
\]

(53)

Then by Theorem 9, the sequence \( \{x_n\} \) is generated by

\[
x_{n+1} = \frac{1}{4(n + 2)} x_n - \frac{n + 1}{n + 2} \left( x_n - \frac{1}{10} B^* Bx_n + \frac{1}{10} B^* b - \frac{1}{10(n + 2)} x_n \right).
\]

(54)

As \( n \to \infty \), we have \( \{x_n\} \to x^* = (2, -5, 3)^T \) (Table 1).

### Conflict of Interests

The authors declare that there is no conflict of interests regarding the publication of this paper.

### Authors’ Contribution

All the authors read and approved the final paper.

### Acknowledgments

The authors thank the referees for their helping comments, which notably improved the presentation of this paper. This work was supported by the Foundation of Tianjin Key Lab for Advanced Signal Processing and by the Fundamental Research Funds for the Central University (no. 3122014K012).
