1. Introduction

The idea of convergence of real sequences had been extended to statistical convergence by Fast [1] and basic ideas were further developed in [2–5]. Recall that “asymptotic density” of a set $A \subseteq \mathbb{N}$ is defined as

$$d(A) = \lim_{n \to \infty} \frac{1}{n} \left| \{k \leq n : k \in A \} \right|,$$

provided that the limit exists, where $\mathbb{N}$ denotes the set of natural numbers and the vertical bar stands for cardinality of the enclosed set. The sequence $\{p_n\}_{n \in \mathbb{N}}$ of reals is said to be statistically convergent to a real number $p$ if, for each $\varepsilon > 0$,

$$\lim_{n \to \infty} \frac{1}{n} \left| \{k \leq n : |x_k - x| \geq \varepsilon \} \right| = 0.$$

The concepts of $\mathcal{F}$ and $\mathcal{F}^*$-convergence, two important generalizations of statistical convergence, were introduced and investigated by Kostyrko et al. [6]. The ideas were based on the notion of ideal $\mathcal{F}$ of $\mathbb{N}$. Subsequently, a lot of investigations have been done on ideal convergence (see [7–17] where many more references both on ideal as well as statistical convergence can be found). Very recently, ideals were used in a different way to generalize the notion of statistical convergence [18, 19] and certain new and summability methods were introduced and their basic properties were investigated. More recently these ideas were extended to double sequences in [20].

On the other hand, the idea of probabilistic metric space was first introduced by Menger [21] in the name of “statistical metric space.” Probabilistic normed space (briefly PN space) is a generalisation of an ordinary normed linear space. In a PN space, the norms of the vectors are represented by the distribution functions instead of nonnegative real numbers. Detailed theory of these spaces can be found in the famous book written by Schweizer and Sklar [22] and the monogram [23]. One can also see the papers [22, 24–35] where the basic ideas were established. Several topologies can be defined on this space. But the topology that was found to be most useful is the “strong topology.” Şençimen and Pehlivan have very recently extended the notion of strong convergence to strong statistical convergence in probabilistic metric spaces [36] and carried out further investigations on statistical continuity and statistical $D$-boundedness in PN spaces [37, 38]. These were followed by the studies of strong ideal convergence in PM and PN spaces in [10, 13, 39], studies of lacunary statistical...
Abstract and Applied Analysis

convergence in PN spaces in [40]. As a natural extension, we had recently introduced the idea of strong \( J \)-statistical convergence in PM spaces [41] and as a followup in this paper we investigate the notion of strong \( J \)-statistical limit and cluster points in PN spaces. Further, we have introduced the concepts like strong \( J \)-statistical continuity and strong \( J \)-statistical \( D \)-boundedness in such spaces and investigated some of their important properties.

2. Preliminaries

First, we recall some of the basic concepts related to the theory of probabilistic metric and normed spaces (see [22, 23, 31–39, 42] for more details).

Definition 1. A nondecreasing function \( F : \mathbb{R} \rightarrow [0, 1] \) defined on \( \mathbb{R} \) with \( F(-\infty) = 0 \) and \( F(\infty) = 1 \), where \( \mathbb{R} = [-\infty, \infty] \), is called a distribution function.

The set of all left continuous distribution functions over \( (-\infty, \infty) \) is denoted by \( \Delta \). One considers the relation "\( \leq^* \)" on \( \Delta \) defined by \( F \leq G \) if and only if \( F(x) \leq G(x) \) for all \( x \in \mathbb{R} \). It can be easily verified that the relation "\( \leq^* \)" is a partially order on \( \Delta \).

Definition 2. For any \( a \in \mathbb{R} \), the unit step function at \( a \) is denoted by \( \varepsilon_a \), and is defined to be a function in \( \Delta \) given by

\[
e_a(x) = \begin{cases} 0, & \text{if } -\infty < x \leq a, \\ 1, & \text{if } a < x < \infty. \end{cases}
\] (3)

Definition 3. A sequence \( \{F_n\}_{n \in \mathbb{N}} \) of distribution functions converges weakly to a distribution function \( F \) and one writes \( F_n \rightharpoonup F \) if and only if the sequence \( \{F_n(x)\}_{n \in \mathbb{N}} \) converges to \( F(x) \) at each continuity point \( x \) of \( F \).

Definition 4. The distance between \( F \) and \( G \) in \( \Delta \) is denoted by \( d_\Delta(F, G) \) and is defined as the infimum of all numbers \( h \in (0, 1] \) such that the inequalities

\[
F(x - h) - h \leq G(x) \leq F(x + h) + h, \\
G(x - h) - h \leq F(x) \leq G(x + h) + h
\] hold for every \( x \in (-1/h, 1/h). \)

Here, we are interested in the subset of \( \Delta \) consisting of those elements \( F \) that satisfy \( F(0) = 0 \).

Definition 5. A distance distribution function is a nondecreasing function \( F \) defined on \( \mathbb{R}^+ = [0, \infty) \) such that \( F(0) = 0 \) and \( F(\infty) = 1 \) and is left continuous on \( (0, \infty) \).

The set of all distance distribution functions is denoted by \( \Delta^+ \). The function \( d_\Delta \) is clearly a metric on \( \Delta^+ \). The metric space \((\Delta^+, d_\Delta)\) is compact and hence complete.

Theorem 6. Let \( F \in \Delta^+ \) be given. Then, for any \( t > 0, F(t) > 1 - t \) if and only if \( d_\Delta(F, \varepsilon_0) < t \).

Note. Geometrically, \( d_\Delta(F, \varepsilon_0) \) is the abscissa of the point of intersection of the line \( y = 1 - x \) and the graph of \( F \) (if necessary we add vertical line segment at the point of discontinuity).

Definition 7. A triangular norm (briefly, a \( t \)-norm) \( T \) is a binary operation on the unit interval \( T : [0, 1] \times [0, 1] \rightarrow [0, 1] \) that is associative, commutative, nondecreasing in each place, and has 1 as identity. The operations defined by \( M(x, y) = \min\{x, y\} \) and \( \pi(x, y) = xy \) are particular \( t \)-norms. Given a \( t \)-norm \( T \), its \( T \)-conorm \( T^* \) is defined as a mapping on \( [0, 1] \times [0, 1] \) by \( T^*(x, y) = 1 - T(1 - x, 1 - y) \).

Definition 8. A triangle function is a binary operation \( \tau \) on \( \Delta^+ \), \( \tau : \Delta^+ \times \Delta^+ \rightarrow \Delta^+ \), which is commutative, associative, and nondecreasing in each place, and has \( \varepsilon_0 \) as identity. Triangle functions can be constructed through left-continuous \( t \)-norms. If \( T \) is such a \( T \)-norm, then

\[
\tau_T(F, G)(x) = \sup \{T(F(s), G(t)) : s + t = x\}
\] (5)
is a triangle function, where \( x \in \mathbb{R}^+ \). If, moreover, \( T \) is continuous, then \( \tau_T \) is uniformly continuous on \((\Delta^+, d_L)\). If \( T^* \) is a continuous \( t \)-conorm, then

\[
\tau_{T^*}(F, G)(x) = \inf \{T^*(F(s), G(t)) : s + t = x\}
\] (6)
is a triangle function which is uniformly continuous on \((\Delta^+, d_L)\).

Definition 9. A probabilistic metric space (briefly a PM space) is a triplet \((X, \mathbb{F}, \tau)\) where \( X \) is a nonempty set, \( \mathbb{F} \) is a function from \( X \times X \) into \( \Delta^+ \), and \( \tau \) is a triangle function. The following conditions are satisfied for all \( x, y, z \in X \):

\begin{align*}
(PM1) & \; \mathbb{F}(x, x) = \varepsilon_0; \\
(PM2) & \; \mathbb{F}(x, y) \neq \varepsilon_0 \text{ if } x \neq y; \\
(PM3) & \; \mathbb{F}(x, y) = \mathbb{F}(y, x); \\
(PM4) & \; \mathbb{F}(x, z) \geq \tau(\mathbb{F}(x, y), \mathbb{F}(y, z)).
\end{align*}

In the sequel, we will denote \( \mathbb{F}(x, y) \) by \( F_{xy} \) and its value at \( t \) by \( F_{xy}(t) \).

Definition 10. A probabilistic normed space (briefly a PN space) is a quadruple \((X, \eta, \tau, \tau^*)\), where \( X \) is a real linear space, \( \tau \) and \( \tau^* \) are continuous triangle functions with \( \tau \leq \tau^* \), and \( \eta \) is a mapping (the probabilistic norm) from \( X \) into the space of distribution functions \( \Delta^+ \) such that, writing \( N_\eta \) for \( \eta(p) \) for all \( p, q \in X \), the following conditions hold:

\begin{align*}
(N1) & \; N_\eta = \varepsilon_0 \text{ if and only if } p = \theta, \text{ the null vector in } X; \\
(N2) & \; N_{-p} = N_{-p}; \\
(N3) & \; N_{p+q} \geq \tau(N_{p}, N_{q}); \\
(N4) & \; N_{p} \leq \tau^*(N_{\alpha p}, N_{(1-\alpha)q}) \text{ for all } \alpha \in [0, 1].
\end{align*}

A Menger PN space under \( T \) is a PN space \((X, \eta, \tau, \tau^*)\) in which \( \tau = \tau_\rightarrow \) and \( \tau^* = \tau_\rightarrow^* \) for some continuous \( t \)-norm \( T \) and its \( t \)-conorm \( T^* \). It is denoted by \((X, \eta, T)\).

Throughout the text, \( X \) will represent the PN space \((X, \eta, \tau, \tau^*)\).
Theorem 11. Let \((X, \eta, \tau, \tau^*)\) be a probabilistic normed space and let \(\mathcal{K}\) be the function from \(X \times X\) to \(\Delta^+\) defined by
\[
\mathcal{K}(x, y) = \eta(x - y) = N_{x-y}.
\]
(7)
Then, \((X, \eta, \tau, \tau^*)\) is a probabilistic metric space (briefly PM space).

Definition 12. Let \(X\) be a PN space. For \(x \in X\) and \(t > 0\), the strong \(t\)-neighbourhood of \(p\) is defined as the set
\[
\mathcal{N}'_{p}(t) = \{q \in X : d_k(N_{p,q}, e_0) < t\}.
\]
(8)
Since \(t\) is continuous, strong neighbourhood system \(\mathcal{B} = \{\mathcal{N}'_{p}(t) : t > 0, p \in X\}\) that determines a Hausdorff and first countable topology for \(X\). This topology is called the strong topology for \(X\).

Remark 13. Throughout the rest of this paper, we always assume that in a PN space \(X\) the triangle function \(\tau\) is continuous and \(X\) is endowed with strong topology.

Definition 14. A sequence \(\{p_n\}_{n \in \mathbb{N}}\) in the PN space \(X\) is said to be strongly convergent to a point \(p \in X\) and one writes \(p_n \to p\) or \(\lim_{n \to \infty} p_n = p\) if for any \(t > 0\) there exists a natural number \(N\) such that \(p_n \in \mathcal{N}'_{p}(t)\) whenever \(n \geq N\).

Definition 15. Given a nonempty set \(A\) in the PN space \(X\), its probabilistic radius \(R_A\) is defined by
\[
R_A(x) = \begin{cases} 
\Gamma^{-1} \phi_A(x), & \text{if } x \in [0, \infty), \\
1, & \text{if } x = \infty,
\end{cases}
\]
(9)
where \(\Gamma^{-1} f(x)\) denotes the left limit of the function \(f\) at the point \(x\) and \(\phi_A(x) = \inf\{N_p(x) : p \in A\}\).

Definition 16. A nonempty set \(A\) in a PN space \(X\) is said to be
(1) certainly bounded if \(R_A(x_0) = 1\) for some \(x_0 \in (0, \infty)\);
(2) perhaps bounded if \(R_A(x) < 1\) for every \(x \in (0, \infty)\) and \(\Gamma^{-1} R_A(+\infty) = 1\);
(3) perhaps unbounded if \(R_A(x_0) > 0\) for some \(x_0 \in (0, \infty)\) and \(\Gamma^{-1} R_A(+\infty) \in (0, 1)\);
(4) certainly unbounded if \(\Gamma^{-1} R_A(+\infty) = 0\) that is, if \(R_A = \epsilon_\infty\).

Moreover, \(A\) is said to be distributionally bounded (D-bounded) if either (1) or (2) holds; that is, if \(R_A \in D^+ = \{F \in \Delta^+ : \Gamma^{-1} F(+\infty) = 1\}\); otherwise, if \(R_A \in \Delta^+ \setminus D^+\), then \(A\) is said to be \(D\)-unbounded.

In the following, we now recall some of the basic concepts related to ideals.

Definition 17. Let \(X\) be any nonempty set. A nonempty family \(\mathcal{J} \subseteq \mathcal{P}(X)\) is called an ideal in \(X\) if
(1) \(A, B \in \mathcal{J}\) implies \(A \cup B \in \mathcal{J}\);
(2) \(A \in \mathcal{J}\) and \(B \subseteq A\) imply \(B \in \mathcal{J}\).

Definition 18. Let \(X\) be any nonempty set. A nonempty family \(\mathcal{F} \subseteq \mathcal{P}(X)\) is called a filter in \(X\) if
(1) \(\emptyset \notin \mathcal{F}\);
(2) \(A, B \in \mathcal{F}\) implies \(A \cap B \in \mathcal{F}\);
(3) \(A \in \mathcal{F}\) and \(\emptyset \subseteq B \) imply \(B \in \mathcal{F}\).

If \(\mathcal{I}\) is an ideal in \(X\), then \(\mathcal{F}(\mathcal{I}) = \{X \setminus A : A \in \mathcal{I}\}\) is a filter in \(X\), which is called the filter associated with the ideal \(\mathcal{I}\). An ideal \(\mathcal{I}\) in \(X\) is called proper if and only if \(\mathcal{I} \notin \emptyset\). An ideal is called an admissible ideal if it is proper and contains \(\{x\}\) for all \(x \in X\).

Definition 19. An admissible ideal \(\mathcal{I}\) is said to satisfy the condition (AP) if, for every countable family of mutually disjoint sets \(\{A_1, A_2, \ldots\}\) belonging to \(\mathcal{I}\), there exists a countable family of sets \(\{B_1, B_2, \ldots\}\) such that \(A_j \Delta B_j\) is a finite set for every \(j \in \mathbb{N}\) and \(B = \bigcup_{j=1}^{\infty} B_j \in \mathcal{I}\).

Throughout the paper, \(\mathcal{I}\) stands for a nontrivial admissible ideal of \(\mathbb{N}\) and \(\mathcal{F}(\mathcal{I})\) is the filter associated with the ideal \(\mathcal{I}\) of \(\mathbb{N}\).

Definition 20 (see [18]). A sequence of real numbers \(\{x_n\}_{n \in \mathbb{N}}\) is said to be \(\mathcal{F}\)-statistically convergent to \(x\) if, for each \(\epsilon > 0\) and \(\delta > 0\),
\[
\left\{n \in \mathbb{N} : \frac{1}{n} \left| \left| \left\{k \leq n : |x_k - x| > \epsilon \right\} \right| \right| \geq \delta \right\} \in \mathcal{F}.
\]
(10)
In this case, we write \(x_n \to x\) (\(S(\mathcal{F})\)).

Definition 21 (see [41]). A sequence \(\{x_n\}_{n \in \mathbb{N}}\) in a PM space \((X, \mathcal{K}, \tau)\) is said to be strongly \(\mathcal{F}\)-statistically convergent to \(x\) if, for each \(\epsilon > 0\) and \(\delta > 0\),
\[
\left\{n \in \mathbb{N} : \frac{1}{n} \left| \left| \left\{k \leq n : |x_k - x| \notin \mathcal{N}'_{x}(\epsilon) \right\} \right| \right| \geq \delta \right\} \in \mathcal{F}.
\]
(11)
In this case, we write \(x_n \to x\) (\(S_{PM}(\mathcal{F})\)) and the class of all strong \(\mathcal{F}\)-statistically convergent sequences is simply denoted by \(S_{PM}(\mathcal{F})\).

Definition 22 (see [41]). A sequence \(\{x_n\}_{n \in \mathbb{N}}\) in a PM space \((X, \mathcal{K}, \tau)\) is said to be strongly \(\mathcal{F}\)-statistically Cauchy if, for every \(\epsilon > 0\), there exists a positive integer \(N = N(\epsilon)\) such that, for any \(\delta > 0\),
\[
\left\{n \in \mathbb{N} : \frac{1}{n} \left| \left| \left\{k \leq n : x_k \notin \mathcal{N}'_{x_N}(\epsilon) \right\} \right| \right| \geq \delta \right\} \in \mathcal{F}.
\]
(12)

3. Strong \(\mathcal{F}\)-Statistical Limit Points and Strong \(\mathcal{F}\)-Statistical Cluster Points in Probabilistic Normed Spaces

In this section, we extend the notions of strong statistical limit points and strong statistical cluster points in PN spaces using ideals. Let \((X, \eta, \tau, \tau^*)\) be a PN space.

Definition 23 (see [36]). Let \(\{p_n\}_{n \in \mathbb{N}}\) be a sequence in \(X\). We say that a point \(p \in X\) is a strong limit point of \(\{p_n\}_{n \in \mathbb{N}}\)
provided that there exists a subsequence of \( \{p_n\}_{n \in \mathbb{N}} \) that strongly converges to \( p \). We denote the set of all strong limit points of \( \{p_n\}_{n \in \mathbb{N}} \) by \( L_1(p_n) \).

**Definition 24.** Let \( \{p_n\}_{n \in \mathbb{N}} \) be a sequence in \( X \) and let \( \{p_n\}_{n \in \mathbb{N}} \) be a subsequence of \( \{p_n\}_{n \in \mathbb{N}} \). Denote \( K = \{n_1 < n_2 < \cdots \} = \{n_j : j \in \mathbb{N}\} \). If, for all \( \delta > 0 \),

\[
\left\{ n \in \mathbb{N} : \frac{1}{n} \left| \left\{ k \leq n : k \in K \right\} \right| \geq \delta \right\} \in \mathcal{F},
\]

then we say that \( \{p_n\}_{n \in \mathbb{N}} \) is an \( \mathcal{F} \)-statistical thin subsequence of \( \{p_n\}_{n \in \mathbb{N}} \). If, for some \( \delta > 0 \),

\[
\left\{ n \in \mathbb{N} : \frac{1}{n} \left| \left\{ k \leq n : k \in K \right\} \right| \geq \delta \right\} \notin \mathcal{F},
\]

then \( \{p_n\}_{n \in \mathbb{N}} \) is called an \( \mathcal{F} \)-statistical nonthin subsequence of \( \{p_n\}_{n \in \mathbb{N}} \).

In this sequel, we will abbreviate the subsequence \( \{p_{n_j}\}_{k \in \mathbb{N}} \) of \( \{p_n\}_{n \in \mathbb{N}} \) as \( \{p_k\} \), where \( K = \{n_1 < n_2 < \cdots \} \).

**Definition 25.** Let \( \{p_n\}_{n \in \mathbb{N}} \) be a sequence in \( X \). An element \( q \in X \) is a strong \( \mathcal{F} \)-statistical limit point of \( \{p_n\}_{n \in \mathbb{N}} \) provided that there exists a set \( M = \{m_1 < m_2 < \cdots \} \subset \mathbb{N} \) such that, for some \( \delta > 0 \),

\[
\left\{ n \in \mathbb{N} : \frac{1}{n} \left| \left\{ k \leq n : k \in M \right\} \right| \geq \delta \right\} \notin \mathcal{F},
\]

and the subsequence \( \{p_{m_k}\}_{k \in \mathbb{N}} \) strongly converges to \( q \). We denote the set of all strong \( \mathcal{F} \)-statistical limit points of \( \{p_n\}_{n \in \mathbb{N}} \) by \( \Lambda_{\mathcal{F}}(\mathcal{F})(p_n) \).

**Definition 26.** Let \( \{p_n\}_{n \in \mathbb{N}} \) be a sequence in \( X \). An element \( r \in X \) is a strong \( \mathcal{F} \)-statistical cluster point of \( \{p_n\}_{n \in \mathbb{N}} \) provided that for every \( \epsilon > 0 \) there is a \( \delta = \delta(\epsilon) > 0 \) such that

\[
\left\{ n \in \mathbb{N} : \frac{1}{n} \left| \left\{ k \leq n : d_L(N_{p_n - r}, \epsilon_0) < \epsilon \right\} \right| \geq \delta \right\} \notin \mathcal{F}.
\]

We denote the set of all strong \( \mathcal{F} \)-statistical cluster points of \( \{p_n\}_{n \in \mathbb{N}} \) by \( \Gamma_{\mathcal{F}}(\mathcal{F})(p_n) \).

**Theorem 27.** For any sequence \( \{p_n\}_{n \in \mathbb{N}} \) in \( X \), one has \( \Lambda_{\mathcal{F}}(\mathcal{F})(p_n) \subseteq \Gamma_{\mathcal{F}}(\mathcal{F})(p_n) \subseteq L_1(p_n) \).

**Proof.** Assume that \( q \in \Lambda_{\mathcal{F}}(\mathcal{F})(p_n) \). Then, there exists a set \( M = \{m_1 < m_2 < \cdots \} \) such that, for some \( \delta > 0 \), say \( \delta_0 \), \( \{n \in \mathbb{N} : (1/n) \left| \left\{ k \leq n : k \in M \right\} \right| \geq \delta_0 \} \notin \mathcal{F} \) and the subsequence \( \{p_{m_k}\}_{k \in \mathbb{N}} \) of \( \{p_n\}_{n \in \mathbb{N}} \) strongly converges to \( q \). Now, for every \( \epsilon > 0 \), \( \{n \in \mathbb{N} : d_L(N_{p_n - r}, \epsilon_0) < \epsilon \} \supseteq \{n \in \mathbb{N} : n \in M \} \supseteq \{n \in \mathbb{N} : d_L(N_{p_n - r}, \epsilon_0) < \epsilon \} \geq \delta \). Since \( p_{m_k} \to q \) strongly, the set \( \{m_k \in M : d_L(N_{p_n - r}, \epsilon_0) \geq \epsilon \} \) is finite for every \( \epsilon > 0 \). Let \( \epsilon > 0 \) be given. If possible let, for every \( \delta > 0 \),

\[
\left\{ n \in \mathbb{N} : (1/n) \left| \left\{ k \leq n : p_k \in \mathcal{N}_r(t) \right\} \right| \geq \delta \right\} \notin \mathcal{F}.
\]

Hence, we get, for any \( \delta > 0 \),

\[
\left\{ n \in \mathbb{N} : \frac{1}{n} \left| \left\{ k \leq n : p_k \in \mathcal{N}_r(t) \right\} \right| \geq \delta \right\} \subseteq \left\{ n \in \mathbb{N} : \frac{1}{n} \left| \left\{ k \leq n : p_k \notin \mathcal{N}_r(t) \right\} \right| \geq \delta \right\}.
\]
Since $p_n \rightarrow p$ (SPM($\mathcal{F}$)), the set on the right-hand side belongs to $\mathcal{J}$. This implies that, for the chosen $t > 0$, $\{n \in \mathbb{N} : (1/n)|k \leq n : k \in K| \geq \delta\} \in \mathcal{F}$ for every $\delta > 0$. This contradicts the fact that $r \in \Gamma_{\mathcal{J}}(p_n)$. Therefore, we have $\Gamma_{\mathcal{J}}(p_n) = \{p\}$.

**Theorem 29.** For any sequence $\{p_n\}_{n \in \mathbb{N}}$ in $X$, the set $\Gamma_{\mathcal{J}}(p_n)$ of strong $\mathcal{J}$-statistical cluster points of $\{p_n\}_{n \in \mathbb{N}}$ is strongly closed.

**Proof.** Let $p \in \kappa(\Gamma_{\mathcal{J}}(p_n))$, where $\kappa(A)$ denotes the strong closure of the set $A$ (see [22]). Choose $t > 0$. Then, $\Gamma_{\mathcal{J}}(p_n) \cap N_p(t) \neq \emptyset$. Let $r \in \Gamma_{\mathcal{J}}(p_n) \cap N_p(t)$. Choose $t' > 0$ in such a way that $N_p(t') \subseteq N_p(t)$. Since $r \in \Gamma_{\mathcal{J}}(p_n)$, there exists a $\delta_1 > 0$ such that $\{n \in \mathbb{N} : (1/n)|k \leq n : k \in K| < \delta_1\} \in \mathcal{F}$. Since $N_p(t') \subseteq N_p(t)$, it follows that

$$\begin{align*}
\{n \in \mathbb{N} : & \frac{1}{n}\{|k \leq n : p_k \in N_{\mathcal{J}}(t')\} \geq \delta_1\} \\
\subseteq & \{n \in \mathbb{N} : \frac{1}{n}\{|k \leq n : p_k \in N_{\mathcal{J}}(t)\} \geq \delta_1\}. \tag{21}
\end{align*}$$

As $\{n \in \mathbb{N} : (1/n)|k \leq n : k \in K| \geq \delta_1\} \notin \mathcal{F}$, consequently $\{n \in \mathbb{N} : (1/n)|k \leq n : k \in K| \geq \delta\} \notin \mathcal{F}$. Hence, $p \in \Gamma_{\mathcal{J}}(p_n)$; that is, $\kappa(\Gamma_{\mathcal{J}}(p_n)) \subseteq \Gamma_{\mathcal{J}}(p_n)$. This proves that $\Gamma_{\mathcal{J}}(p_n)$ is strongly closed.

**Theorem 30.** If $\{p_n\}_{n \in \mathbb{N}}$ and $\{q_n\}_{n \in \mathbb{N}}$ are two sequences in $X$ and there exists a set $M = \{m_1 < m_2 < \cdots \} \subseteq \mathbb{N}$ such that $\{n \in \mathbb{N} : (1/n)|k \leq n : k \in M| \geq \delta\} \in \mathcal{F}$ and $p_{n_k} \rightarrow q_{n_k}$, for all $k \in \mathbb{N}$, then $\Lambda_{\mathcal{J}}(p_n) = \Lambda_{\mathcal{J}}(q_n)$ and $\Gamma_{\mathcal{J}}(p_n) = \Gamma_{\mathcal{J}}(q_n)$.

**Proof.** Assume that $ua \in \Lambda_{\mathcal{J}}(p_n)$. Let $\{p_k\}_{k \in \mathbb{N}}$ be an $\mathcal{J}$-statistical nonthinning subsequence of $\{p_n\}_{n \in \mathbb{N}}$ that strongly converges to $u$, where $K = \{m_1 < m_2 < \cdots \}$. Since $\{n \in \mathbb{N} : (1/n)|k \leq n : k \in M| \geq \delta\} \in \mathcal{F}$, and $p_{n_k} \rightarrow q_{n_k}$, for all $k \in \mathbb{N}$, $\Lambda_{\mathcal{J}}(p_n) = \Lambda_{\mathcal{J}}(q_n)$ and $\Gamma_{\mathcal{J}}(p_n) = \Gamma_{\mathcal{J}}(q_n)$.

Since $p_n \rightarrow p$ (SPM($\mathcal{F}$)), the set on the right-hand side belongs to $\mathcal{J}$. Consequently, for any $t > 0$, $\{n \in \mathbb{N} : (1/n)|k \leq n : d_{\mathcal{J}}(N_{\mathcal{J}}(p_n), N_{\mathcal{J}}) \geq \delta\} \subseteq \mathcal{F}$. Hence, by definition, we have $N_{\mathcal{J}}(p_n) \rightarrow N_{\mathcal{J}}(p)$ (SPM($\mathcal{F}$)). This means that $\eta$ is a strongly $\mathcal{J}$-statistically continuous mapping.

**Theorem 33.** Let $(X, \eta, \tau, \tau^*)$ be a PN space. Let $X$ be endowed with the strong topology and let $\Delta^*$ be endowed with the $d_{\mathcal{J}}$-metric topology. Then, $\eta$ is a strongly $\mathcal{J}$-statistically continuous mapping from $X \times X$ to $X$.

**Proof.** Let $\{p_n\}_{n \in \mathbb{N}}$ and $\{q_n\}_{n \in \mathbb{N}}$ be two sequences in $X$ such that $p_n \rightarrow p$ (SPM($\mathcal{F}$)) and $q_n \rightarrow q$ (SPM($\mathcal{F}$)). As $N_{\mathcal{J}}(p_{n_k}, q_{n_k}) \rightarrow \tau(N_{\mathcal{J}}(p_{m_j}), q_{n_k})$, $d_{\mathcal{J}}(N_{\mathcal{J}}(p_{n_k}), q_{n_k}) \leq d_{\mathcal{J}}(\tau(N_{\mathcal{J}}(p_{m_j}), q_{n_k}), q_{n_k})$ for every $n \in \mathbb{N}$. Again since continuity of $\tau$ implies its uniform continuity, it follows that for any $t > 0$, there is a $\lambda > 0$ such that $d_{\mathcal{J}}(\tau(F, G), q_{n_k}) < t$ whenever $d_{\mathcal{J}}(F, q_{n_k}) < \lambda$ and $d_{\mathcal{J}}(G, q_{n_k}) < \lambda$, where $F, G \in \Delta^*$. Now, let $t > 0$. Then, we can find a $\lambda > 0$ such that $d_{\mathcal{J}}(\tau(N_{\mathcal{J}}(p_{m_j}), q_{n_k}), q_{n_k}) < t$ whenever $d_{\mathcal{J}}(N_{\mathcal{J}}(p_{m_j}), q_{n_k}) < \lambda$ and $d_{\mathcal{J}}(\tau(N_{\mathcal{J}}(p_{m_j}), q_{n_k}), q_{n_k}) < \lambda$. Hence, $d_{\mathcal{J}}(N_{\mathcal{J}}(p_{m_j}), q_{n_k}) < \lambda$ whenever $p_n \in N_{\mathcal{J}}^*(p)$ and $q_n \in N_{\mathcal{J}}^*(q)$. Thus, we have, for all $t > 0$,

$$\begin{align*}
\{n \in \mathbb{N} : d_{\mathcal{J}}(N_{\mathcal{J}}(p_{m_j}), q_{n_k}) \geq \delta\} & \subseteq \{n \in \mathbb{N} : p_n \notin N_{\mathcal{J}}^*(p)\} \cup \{n \in \mathbb{N} : q_n \notin N_{\mathcal{J}}^*(q)\}. \tag{23}
\end{align*}$$

Definition 31. Let $(X, \eta, \tau, \tau^*)$ and $(Y, \nu, \tau^*)$ be two probabilistic normed spaces. A function $f : X \rightarrow Y$ is said to be strongly $\mathcal{J}$-statistically continuous at a point $x_0 \in X$ if $x_n \rightarrow x_0$ (SPM($\mathcal{F}$)) implies that $f(x_n) \rightarrow f(x_0)$ (SPM($\mathcal{F}$)).
Therefore, we have, for all $t > 0$ and $\delta > 0$,
\[
\left\{ n \in \mathbb{N} : \frac{1}{n} \left| \left\{ k \leq n : d_L \left( N(p_k, q_k, \epsilon_0 \right) > t \right\} \right| > \frac{\delta}{2} \right\}
\]
\[\subseteq \left\{ n \in \mathbb{N} : \frac{1}{n} \left| \left\{ k \leq n : \epsilon_k \notin A^p (\lambda) \right\} \right| \geq \frac{\delta}{2} \right\}
\]
\[\cup \left\{ n \in \mathbb{N} : \frac{1}{n} \left| \left\{ k \leq n : \epsilon_k \notin A^q (\lambda) \right\} \right| \geq \frac{\delta}{2} \right\}.
\] (24)

Since $p_n \to p (S_{PM}(\mathcal{F}))$ and $q_n \to q (S_{PM}(\mathcal{F}))$, each set on the right-hand side belongs to $\mathcal{F}$ and so their union also belongs to $\mathcal{F}$. Therefore, we get, for each $t > 0$ and $\delta > 0$, $\{ n \in \mathbb{N} : (1/n) \left| \left\{ k \leq n : d_L \left( N(p_k, q_k, \epsilon_0 \right) > t \right\} \right| > \delta \} \in I$. This shows that $(p_n + q_n) \to (p + q) (S_{PM}(\mathcal{F}))$ which completes the proof.

**Corollary 34.** Let $(X, \eta, \tau, \tau^*)$ be a PN space. The mapping $\nu$ from $X \times X$ to $\Delta^*$ defined as $\nu(p, q) = N_{p+q}$ for any $p, q \in X$ is strongly $\mathcal{F}$-statistically continuous.

**Proof.** Proof of this result immediately follows from Theorems 32 and 33. \[\square\]

We now investigate the strong $\mathcal{F}$-statistical continuity properties of scalar multiplication given by $\mathcal{M}(\alpha, p) = \alpha p$ for all $\alpha \in \mathbb{R}$ and $p \in X$.

**Lemma 35** (see [37]). For any $\alpha \in \mathbb{R}$, $r \in X$, and $h > 0$, there exists a $\lambda > 0$ such that $d_L(N_{\alpha r}, \epsilon_0 < h$ whenever $d_L(N_r, \epsilon_0 < \lambda$.

**Theorem 36.** The mapping $\mathcal{M}$ is strongly $\mathcal{F}$-statistically continuous in its second place; that is, for a fixed $\alpha \in \mathbb{R}$, scalar multiplication is a strongly $\mathcal{F}$-statistically continuous mapping from $F$ to $X$.

**Proof.** Let $\alpha \in \mathbb{R}$ be fixed and let $\{p_n\}_{n \in \mathbb{N}}$ be a sequence in $X$ such that $p_n \to p (S_{PM}(\mathcal{F}))$. Then, by Lemma 35, for any $h > 0$, we can find a $\lambda > 0$ such that $\{ n \in \mathbb{N} : d_L(N_{p_n - \alpha p}, \epsilon_0) < \lambda \} \subseteq \{ n \in \mathbb{N} : d_L(N_{p_n - p}, \epsilon_0) < h \}$. Therefore, for any $\delta > 0$,
\[
\left\{ n \in \mathbb{N} : \frac{1}{n} \left| \left\{ k \leq n : d_L \left( N_{p_k - \alpha p}, \epsilon_0 \right) > h \right\} \right| \geq \delta \right\}
\]
\[\subseteq \left\{ n \in \mathbb{N} : \frac{1}{n} \left| \left\{ k \leq n : d_L \left( N_{p_k - p}, \epsilon_0 \right) > \lambda \right\} \right| \geq \delta \right\}. \] (25)

Since $p_n \to p (S_{PM}(\mathcal{F}))$, the set on the right-hand side belongs to $\mathcal{F}$. Therefore, for any $h > 0$ and $\delta > 0$, $\{ n \in \mathbb{N} : (1/n) \left| \left\{ k \leq n : d_L \left( N_{p_k - p}, \epsilon_0 \right) \right\} \geq h \} \geq \delta \} \in I$. Hence, $\alpha p_n \to \alpha p (S_{PM}(\mathcal{F}))$. \[\square\]

Example 37. Let $X$ be the real line $\mathbb{R}$ viewed as a one-dimensional linear space and let $\tau = \tau_W$ and $\tau^* = \tau_M$, where $\tau_W$ and $\tau_M$ are the continuous triangle functions defined by
\[
(\tau_W(F, G))(t) = \sup \{ \max \{ F(u) + G(v) - 1, 0 \} : u + v = t \},
\]
\[
(\tau_M(F, G))(t) = \sup \{ \min \{ F(u), G(v) \} : u + v = t \}.
\] (26)

For $p \in \mathbb{R}$, define $\eta$ by setting $\eta(0) = \epsilon_0$ and
\[
\eta(p) = N_p = \frac{|p| + 1}{|p|} + \frac{1}{|p| + 2^{\epsilon_0}}, \quad \text{for } p \neq 0. \] (27)

Clearly, $(X, \eta, \tau, \tau^*)$ is a PN space. Choose an infinite set $A \in \mathcal{F}$. Now, consider the real sequence $\{\alpha_n\}_{n \in \mathbb{N}}$ defined by
\[
\alpha_n = \begin{cases} 1, & \text{if } n \in A, \\ \frac{1}{n}, & \text{if } n \notin \mathbb{N} \setminus A. \end{cases} \] (28)

It can be easily shown that $\alpha_n \to 0 (S_{PM}(\mathcal{F}))$ but $d_L(N_{\alpha_n \epsilon_0}, \epsilon_0) \to 0 (S_{PM}(\mathcal{F}))$. This example shows that the mapping from $\mathbb{R}$ into $X$ defined by $\alpha \to \alpha p$ is not strongly $\mathcal{F}$-statistically continuous for any fixed $p \in X$; that is, the mapping $\mathcal{M}$ is not strongly $\mathcal{F}$-statistically continuous in its first place.

A triangle function $\tau^*$ is called Archimedean if $\tau^*$ admits no idempotents other than $\epsilon_0$ and $\epsilon_{\infty}$. More details on Archimedean triangle function can be found in the book [22]. If $\tau^*$ is Archimedean, then we can establish the following lemmas.

**Lemma 38** (see [37]). If $\tau^*$ is Archimedean, then, for any $p \in X$ such that $N_p \neq \epsilon_{\infty}$ and any $h > 0$, there exists a $\beta > 0$ such that $d_L(N_{\alpha p}, \epsilon_0 < h$ whenever $|\alpha| < \beta$.

**Theorem 39.** If $(X, \eta, \tau, \tau^*)$ is PN space such that $\tau^*$ is Archimedean and if $N_p \neq \epsilon_{\infty}$ for every $p \in X$, then for any fixed $p \in X$ the mapping $\mathcal{M}$ is strongly $\mathcal{F}$-statistically continuous in its first place.

**Proof.** To $\mathcal{F} \times \mathcal{F}$ be fixed and let $\{\alpha_n\}_{n \in \mathbb{N}}$ be a real sequence such that $\alpha_n \to \alpha (S(\mathcal{F}))$. Let $h > 0$ be given. By Lemma 38, we can find a $\beta > 0$ such that $d_L(N_{|\alpha - \alpha| \epsilon_0}, \epsilon_0 < h$ whenever $|\alpha - \alpha| < \beta$. In particular, $|\alpha_n - \alpha| < \beta$ implies that $d_L(N_{\alpha_n \epsilon_0}, \epsilon_0) < h$. Therefore, $\{ n \in \mathbb{N} : d_L(N_{\alpha_n \epsilon_0}, \epsilon_0) \geq h \} \subseteq \{ n \in \mathbb{N} : |\alpha_n - \alpha| \geq \beta \}$. It now readily follows that, for all $\delta > 0$,
\[
\left\{ n \in \mathbb{N} : \frac{1}{n} \left| \left\{ k \leq n : d_L \left( N_{\alpha_k \epsilon_0}, \epsilon_0 \right) > h \right\} \right| \geq \delta \right\}
\]
\[\subseteq \left\{ n \in \mathbb{N} : \frac{1}{n} \left| \left\{ k \leq n : |\alpha_k - \alpha| \geq \beta \right\} \right| \geq \delta \right\}. \] (29)

Since $\alpha_n \to \alpha (S(\mathcal{F}))$, the set on the right-hand side belongs to $\mathcal{F}$ and, consequently, for any $\delta > 0$ and $h > 0$, $\{ n \in \mathbb{N} : (1/n) \left| \left\{ k \leq n : d_L \left( N_{\alpha_k \epsilon_0}, \epsilon_0 \right) \right\} \geq h \} \geq \delta \} \in I$. Therefore, $\alpha_n p \to \alpha p (S_{PM}(\mathcal{F}))$ as desired. \[\square\]
The following lemmas will be needed to prove our next result.

**Lemma 40** (see [37]). If \( 0 \leq \alpha \leq \beta \), then \( N_{\beta p} \leq N_{\alpha p} \) for any \( p \in X \).

**Lemma 41** (see [37]). Let \( \tau \) be a continuous triangle function and let \( S \) be the set of all triplets \((F, G, H) \) in \( \Delta^* \times \Delta^* \times \Delta^* \) such that \( F \geq \tau(H, G) \) and \( G \geq \tau(H, F) \). Then, for any \( h > 0 \), there exists a \( \lambda > 0 \) such that if \( (F, G, H) \) is in \( S \) and \( d_1(H, e_\lambda) < \lambda \), then \( d_1(F, G) < h \).

**Theorem 42.** Let \((X, \eta, \tau, \tau^*)\) be a PN space such that \( \tau^* \) is Archimedean and \( N \neq e_\infty \) for all \( p \in X \). Then, the scalar multiplication is a jointly strongly \( \mathcal{F} \)-statistically continuous mapping from \( \mathbb{R} \times X \) endowed with the natural product topology onto \( X \). Furthermore, the mapping \( \mu^* : \mathbb{R} \times X \to \Delta^* \) given by \( \mu^*(\alpha, p) = \eta(\alpha p) = N_{\alpha p} \) for any \( \alpha \in \mathbb{R} \) and any \( p \in X \) is also jointly strongly \( \mathcal{F} \)-statistically continuous.

Proof. Let \( \{p_n\}_{n \in \mathbb{N}} \) be a sequence in \( X \) such that \( p_n \to p \) (\( S_{PM}(\mathcal{F}) \)) and let \( \{\alpha_n\}_{n \in \mathbb{N}} \) be a real sequence such that \( \alpha_n \to \alpha \) (\( S(\mathcal{F}) \)). Consider the set \( M_1 = \{n \in \mathbb{N} : |\alpha_n - \alpha| < 1\} \). Since \( \alpha_n \to \alpha \) (\( S(\mathcal{F}) \)), we have, for every \( \delta > 0 \),

\[
\{n \in \mathbb{N} : |\alpha_n - \alpha| < 1\} \subseteq \{n \in \mathbb{N} : |\alpha_n - \alpha| < \delta\} \subseteq \mathbb{N}
\]

Hence, \( \{n \in \mathbb{N} : d_1(N_{\alpha_n p}, e_\lambda) < \delta\} \subseteq \{n \in \mathbb{N} : |\alpha_n - \alpha| < \delta\} \subseteq \mathbb{N} \).

\[
\mu(\alpha, p_n) = \eta(\alpha p_n) = N_{\alpha p_n} \to \eta(\alpha p) = N_{\alpha p}
\]

Therefore, for any \( \delta > 0 \), we can find a \( \lambda > 0 \) such that \( d_1(N_{\alpha p}, e_\lambda) < \delta \).

5. Strong \( \mathcal{F} \)-Statistically \( D \)-Bounded Sequences in Probabilistic Normed Spaces

**Definition 43** (see [38]). Let \((X, \eta, \tau, \tau^*)\) be a PN space. A sequence \( \{p_n\}_{n \in \mathbb{N}} \) in \( X \) is statistically \( D \)-bounded provided that there exists a set \( K = \{n_1 < n_2 < \cdots \} \subset \mathbb{N} \) with \( \delta(K) = \lim_{n \to \infty} (1/n) \sum |k \leq n : k \notin K| \geq \delta \) in \( \mathcal{F} \) for any \( \delta > 0 \) and \( \{p_n\}_{n \in \mathbb{N}} \) is \( D \)-bounded.

In this section, we generalize the above definition for sequences in a PN space and introduce the concept of a strongly \( \mathcal{F} \)-statistically \( D \)-bounded sequence.

**Definition 44.** Let \((X, \eta, \tau, \tau^*)\) be a PN space. A sequence \( \{p_n\}_{n \in \mathbb{N}} \) in \( X \) is strongly \( \mathcal{F} \)-statistically \( D \)-bounded provided that there exists a set \( K = \{n_1 < n_2 < \cdots \} \subset \mathbb{N} \) such that \( |n \in \mathbb{N} : (1/n) \sum |k \leq n : k \notin K| \geq \delta| \geq \delta \) in \( \mathcal{F} \) for any \( \delta > 0 \) and \( \{p_n\}_{n \in \mathbb{N}} \) is \( D \)-bounded.

Clearly, in this case, \( \mathcal{R}_{\{p_n\}_{n \in \mathbb{N}}} = \mathcal{R}_{\{p_n\}_{n \in \mathbb{N}}} \subset \mathcal{D}^+ \). Note that a \( D \)-bounded sequence is always strongly \( \mathcal{F} \)-statistically \( D \)-bounded, but the converse is not generally true.

**Theorem 45.** A sequence \( \{p_n\}_{n \in \mathbb{N}} \) in the PN space \( X \) is strongly \( \mathcal{F} \)-statistically \( D \)-bounded if and only if there exists a set \( K = \{n_1 < n_2 < \cdots \} \subset \mathbb{N} \) with \( |n \in \mathbb{N} : (1/n) \sum |k \leq n : k \notin K| \geq \delta| \geq \delta \) in \( \mathcal{F} \) for any \( \delta > 0 \) and a distribution function \( G \in \mathcal{D}^* \) such that \( N_{p_n} \geq G \).

Proof. The proof of the theorem immediately follows from Theorem 2.1 of [29] and Definition 44.

**Example 46.** Let us consider the simple space \((\mathbb{R}, |·|, G, M)\), where \(|·|\) denotes the usual norm on \(\mathbb{R} ; G \in \Delta^*, G \neq e_\lambda, e_\infty, e_0,\)
and the probabilistic norm $\eta : \mathbb{R} \to \Delta^+$ is given by $\eta(0) = \varepsilon_0$ and, for $t > 0$, $p \neq 0$,
\begin{equation}
\eta_p(t) = N_p(t) = G \left( \frac{t}{|p|} \right).
\end{equation}

This space is called Menger PN space under $M$ where $M$ is the $t$-norm defined by $M(x, y) = \min\{x, y\}$. Now, assume that there is a $x_0 \in (0, \infty)$ such that $G(x_0) = 1$ and $G(0) = 0$.

Next, assume that $\mathbb{N} = \bigcup_{k=1}^{\infty} D_k$ is a decomposition of $\mathbb{N}$ (i.e., $D_k \cap D_l = \emptyset$ for $k \neq l$) where $D_j = \{1, 2, 3, \ldots\}$ are infinite sets defined as $D_j = \{2^{j-1}(2s - 1) : s \in \mathbb{N}\}$. Denote by $\mathcal{J}$ the class of all $A \subset \mathbb{N}$ such that $A$ intersects only a finite number of $D_j$. It can be easily verified that $\mathcal{J}$ is an admissible ideal. Note that $|D_j(1, n)|/n = (1/n)|\{k \leq n : k \in D_j\}| \leq 1/2^{j-1}$ for all $j \in \mathbb{N}$. Now, for every $\delta > 0$, there exists a $A_0 \in \mathcal{J}$ such that $|D_j(1, n)|/n < 1/2^{j-1} < \delta$. Therefore, in $\mathbb{N}$ the subsequence $\{D_j(1, n)\}_{n \in \mathbb{N}}$ is strongly statistically $\mathcal{J}$-bounded. Hence, $A_0 \in \mathcal{J}$ is certainly unbounded and hence $D$-bounded in $R(\mathbb{R}, |\cdot|, G, M)$. Moreover, the subsequence $\{p_{D_j} \}_{j=1}^{\infty}$ is certainly unbounded in $R(\mathbb{R}, |\cdot|, G, M)$. Therefore, the sequence $\{p_{D_j} \}_{j=1}^{\infty}$ is strongly $\mathcal{J}$-statistically $D$-bounded, but it is not statistically $D$-bounded as $\delta(D_j) \neq 0$.

We now present certain results which are modifications of similar results proved for statistically $D$-bounded sequences [38]. The proofs of these results are parallel to the corresponding results of [38] with necessary modifications.

**Theorem 47.** If $\{p_n\}_{n \in \mathbb{N}}$ is a strongly $\mathcal{J}$-statistically $D$-bounded sequence in the PN space $(\mathbb{X}, \eta, \tau, \tau^\star)$, then there exists a $D$-bounded sequence $\{q_n\}_{n \in \mathbb{N}}$ and a strongly $\mathcal{J}$-statistically null sequence $\{r_n\}_{n \in \mathbb{N}}$ such that $p_n = q_n + r_n$ for all $n \in \mathbb{N}$.

**Proof.** Let $\{p_n\}_{n \in \mathbb{N}}$ be a strongly $\mathcal{J}$-statistically $D$-bounded sequence in the PN space. Then, there exists a set $K = \{n_1 < n_2 < \cdots\} \subset \mathbb{N}$ with $\{n \in \mathbb{N} : (1/n)|\{k \leq n : k \notin K\}| \geq \delta\} \subseteq \mathcal{J}$, for any $\delta > 0$, such that $\{p_K\}$ is $D$-bounded. Now, define
\begin{align*}
q_n &= \begin{cases} 
p_n, & \text{if } n \in K, \\
0, & \text{otherwise},
\end{cases} \\
r_n &= \begin{cases} 
0, & \text{if } n \in K, \\
p_n, & \text{otherwise}.
\end{cases}
\end{align*}

We have, for each $\varepsilon > 0$ and $\delta > 0$,
\begin{align*}
\left\{ n \in \mathbb{N} : \frac{1}{n} \left| \{k \leq n : d_L(N_{r_n}, \varepsilon_0) \geq \varepsilon \} \right| \geq \delta \right\} \\
\subseteq \left\{ n \in \mathbb{N} : \frac{1}{n} \left| \{k \leq n : k \notin K\} \right| \geq \delta \right\}.
\end{align*}

Since the set on the right-hand side belongs to $\mathcal{J}$, $\{n \in \mathbb{N} : (1/n)|\{k \leq n : d_L(N_{r_n}, \varepsilon_0) \geq \varepsilon\} \geq \delta\} \subseteq \mathcal{J}$. Thus, $r_n \to 0$ in $\mathcal{J}$. The sequence $\{q_n\}_{n \in \mathbb{N}}$ is clearly $D$-bounded. It is easy to see that $p_n = q_n + r_n$, where $\{q_n\}_{n \in \mathbb{N}}$ is $D$-bounded and $r_n \to 0$ in $\mathcal{J}$.
there exist sets $K = \{k_1 < k_2 < \cdots\} \subset \mathbb{N}$ and $L = \{l_1 < l_2 < \cdots\} \subset \mathbb{N}$ such that for any $\delta > 0$, $\{n \in \mathbb{N} : (1/n)[k \leq \delta] \geq \delta/2\} \in \mathcal{I}$ and $\{n \in \mathbb{N} : (1/n)[k \leq \delta] \geq \delta/2\} \in \mathcal{J}$. Now, consider the set $K \cap L = \{n_1 < n_2 < \cdots\} \subset \mathbb{N}$. Obviously, $K \cap L \neq \emptyset$.

We also have $\{n \in \mathbb{N} : (1/n) \geq \delta/2\} \subseteq \{n \in \mathbb{N} : (1/n)[k \leq \delta] \geq \delta/2\}$ for any $\delta > 0$. Thus, the sequence $(X, \eta, \tau, \tau^*)$ is $(\mathcal{I}, \mathcal{J})$-invariant under $\tau$.

**Corollary 52.** Let $(X, \eta, \tau, \tau^*)$ be a PN space. If $\mathcal{D}^*$ is invariant under $\tau$, then $(\mathcal{D}^* \times \mathcal{D}^*) \subseteq \mathcal{D}^*$.
