We obtain characterizations of compactness for resolvent families of operators and as applications we study the existence of mild solutions to nonlocal Cauchy problems for fractional derivatives in Banach spaces. We discuss here simultaneously the Caputo and Riemann–Liouville fractional derivatives in the cases $0 < \alpha < 1$ and $1 < \alpha < 2$.

1. Introduction

The nonlocal initial conditions were introduced to extend the classical theory of initial value problems. Nonlocal conditions describe more appropriately some natural phenomena because they consider additional information in the initial conditions.

The existence of mild solutions to semilinear Cauchy problems with nonlocal conditions has been studied by several authors in the last two decades. See, for instance, [1–4] and the references cited therein.

On the other hand, many authors have studied recently the existence of mild solutions to abstract fractional differential equations with nonlocal conditions by using the theory of resolvent families of operators as well as some fixed point results. See [5–18] and the references therein for more details.

Let $A$ be a closed and linear operator defined on a Banach space $X$, $u_0, u_1 \in X$, and $T > 0$ and suppose that $f$, $p$, and $q$ are suitable continuous functions. In what follows, we will denote by $D^\alpha_1$ and $D^\alpha$ the Caputo and Riemann–Liouville fractional derivatives, respectively. Now, for $t \in [0, T]$, we consider the following nonlinear fractional differential equations with nonlocal conditions

\begin{equation}
D^\alpha_1 u(t) = A u(t) + f(t, u(t)),
\end{equation}

\begin{equation}
D^\alpha u(t) = A u(t) + f(t, u(t)), \quad (g_{1-\alpha} * u)(0) = p(u) + u_0,
\end{equation}

in case $0 < \alpha < 1$; and

\begin{equation}
D^\alpha_1 u(t) = A u(t) + f(t, u(t)), \quad u(0) = p(u) + u_0,
\end{equation}

\begin{equation}
D^\alpha u(t) = A u(t) + f(t, u(t)), \quad (g_{2-\alpha} * u)(0) = p(u) + u_0,
\end{equation}

\begin{equation}
(D_{2-\alpha} u)'(0) = q(u) + u_1,
\end{equation}

in case $1 < \alpha < 2$.

By using the Laplace transform, it is easy to see that the mild solutions to problems (1)–(4) are, respectively, given by

\begin{equation}
u(t) = S_{\frac{\alpha}{1}}(t) \left( u_0 + p(u) \right) + \int_{0}^{t} S_{\alpha}(t-s) f(s, u(s)) ds,
\end{equation}

\begin{equation}
u(t) = S_{\frac{\alpha}{1}}(t) \left( u_0 + (u) \right) + \int_{0}^{t} S_{\alpha}(t-s) f(s, u(s)) ds,
\end{equation}
in case $0 < \alpha < 1$; and
\[
 u(t) = S_{\alpha,1}(t)(u_0 + p(u)) + S_{\alpha,2}(t)(u_1 + q(u)) + \int_0^t S_{\alpha,\alpha}(t-s)f(s,u(s))ds,
\]
\[
 u(t) = S_{\alpha,\alpha}(t)(u_0 + p(u)) + S_{\alpha,2}(t)(u_1 + q(u)) + \int_0^t S_{\alpha,\alpha}(t-s)f(s,u(s))ds,
\]
in case $1 < \alpha < 2$. Here, for $\alpha, \beta > 0$, $\{S_{\alpha,\beta}(t)\}_{t \geq 0}$ is the resolvent family generated by $A$ (see definition below, Section 2).

The existence of mild solutions to problems (1)–(4) has been studied by many authors in the last years. For example, in case $0 < \alpha < 1$, we refer the reader to [8, 9, 17, 18] (for the Caputo and Riemann-Liouville fractional derivative) and to [10] (for the Riemann-Liouville fractional derivative), that is, problems (1) and (2), respectively. On the other hand, in case $1 < \alpha < 2$, the existence of mild solutions to the Caputo fractional Cauchy problems with nonlocal conditions (3) has been considered in [12, 19] and the references therein, and, to the best of our knowledge, nonlocal Riemann-Liouville fractional Cauchy problem (4) has not been addressed in the existing literature.

A common assumption in many of the above-mentioned papers to obtain the existence of mild solutions to problems (1)–(4) is that $A$ generates a compact analytic semigroup $\{T(t)\}_{t \geq 0}$ or $A$ generates a compact fractional resolvent family $\{S_{\alpha,1}(t)\}_{t \geq 0}$ (see the definition below) because the compactness of $\{T(t)\}_{t \geq 0}$ (or $\{S_{\alpha,1}(t)\}_{t \geq 0}$) allows applying, for example, the Krasnoselskii fixed point theorem.

According to the variation of constants formulas (5)–(7), we observe that if we have compactness criteria of $S_{\alpha,\beta}(t)$ (for suitable $\alpha$ and $\beta$), we will be able to apply some fixed point techniques to obtain the existence of mild solutions to problems (1)–(4). For example, in Section 2, we will prove the existence of mild solutions to problem (3) under the assumption that the operators $S_{\alpha,1}(t), S_{\alpha,2}(t),$ and $S_{\alpha,\alpha}(t)$ generated by $A$ are compact for all $t > 0$. However, there are not completely clear conditions on $A$ implying the compactness of $S_{\alpha,1}(t), S_{\alpha,2}(t),$ and $S_{\alpha,\alpha}(t)$ for all $t > 0$, because there are no compactness criteria for $S_{\alpha,\beta}(t)$, when $\alpha, \beta > 0$. Therefore, we notice that the compactness of $S_{\alpha,\beta}(t)$ gives a powerful tool to obtain existence of mild solutions to problems (1)–(4).

The compactness of $S_{\alpha,\beta}(t)$ is well known in some special cases. For example, if $\alpha = \beta = 1$, then $S_{1,1}(t)$ is compact for all $t > 0$ if and only if $S_{1,1}(t)$ is norm continuous and $(\lambda - A)^{-1}$ is compact for all $\lambda \in \rho(A)$, because $S_{1,1}(t)_{t \geq 0}$ corresponds to a $C_0$-semigroup. See [20, Theorem 3.3, Chapter 2]. If $\alpha = \beta = 2$, then $S_{2,2}(t)$ is compact for all $t > 0$ if and only if $(\lambda^2 - A)^{-1}$ is compact for all $\lambda \in \rho(A)$, because $S_{2,2}(t)_{t \geq 0}$ is the sine family generated by $A$; see [21]. In case $0 < \alpha < 1$, the compactness of $S_{\alpha,1}(t)$ has been studied by using subordination methods; that is, the operator $A$ is supposed to be a generator of a compact semigroup; see [22]. On the other hand, if $A$ is an almost sectorial operator and the resolvent $(\lambda^\alpha - A)^{-1}$ is compact for all $\lambda \in \rho(A)$, then $S_{\alpha,1}(t)$ is compact for all $t > 0$ (see [23]), and, very recently, it was proved that if $S_{\alpha,1}(t)$ is norm continuous, then $S_{\alpha,\alpha}(t)$ is compact for all $t > 0$ if and only if $(\lambda^\alpha - A)^{-1}$ is compact for all $\lambda \in \rho(A)$. See [24, 25]. Finally, in case $1 < \alpha < 2$, the characterization of compactness asserts that $S_{\alpha,\alpha}(t)$ is compact for all $t > 0$ if and only if $(\lambda^\alpha - A)^{-1}$ is compact for all $\lambda \in \rho(A)$; see [25, Theorem 3.5].

In this paper, we study the existence of mild solution to nonlocal fractional Cauchy problems (1)–(4). Our approach relies on the compactness of resolvent family $\{S_{\alpha,\beta}(t)\}_{t \geq 0}$ for suitable $\alpha, \beta > 0$, as well as some fixed point techniques. We remark that we study simultaneously the nonlocal fractional Cauchy problem for the Caputo and Riemann-Liouville fractional derivatives.

The paper is organized as follows. Section 2 gives the preliminaries. Section 3 is devoted to the norm continuity and compactness of $S_{\alpha,\beta}(t)$ for $t > 0$. Here, we give characterizations of the compactness of $S_{\alpha,\beta}(t)$ for $t > 0$ for suitable $\alpha, \beta > 0$. In Section 4 we study nonlocal fractional Cauchy problems for the Caputo fractional derivative. We give some results on the existence of mild solutions to problems (1) and (3). Section 5 treats nonlocal fractional Cauchy problems for the Riemann-Liouville fractional derivative. Here, we study the existence of mild solutions to problems (2) and (4). Finally, Section 6 is devoted to some applications.

2. Preliminaries

Let $(X, \|\|)$ be a Banach space. We denote by $\mathcal{B}(X)$ the space of all bounded linear operators from $X$ into $X$. If $A$ is a closed linear operator on $X$, we denote by $\rho(A)$ the resolvent set of $A$ and $R(\lambda, A) = (\lambda - A)^{-1}$ the resolvent operator of $A$ defined for all $\lambda \in \rho(A)$.

We recall that a strongly continuous family $\{S(t)\}_{t \geq 0} \subset \mathcal{B}(X)$ is said to be of type $(M, \omega)$ or is exponentially bounded, if there exist two constants $M > 0$ and $\omega \in \mathbb{R}$ such that $\|S(t)\| \leq Me^{\omega t}$ for all $t > 0$.

Now, we review some results on fractional calculus. For $\mu > 0$, define
\[
g_{\mu}(t) = \begin{cases} \frac{t^{\mu-1}}{\Gamma(\mu)}, & t > 0, \\ 0, & t \leq 0, \end{cases}
\]
where $\Gamma(\cdot)$ is the Gamma function. We define $g_0 \equiv \delta_0$, the Dirac delta. For $\mu > 0, n = [\mu]$ denotes the smallest integer $n$ greater than or equal to $\mu$. As usual, the finite convolution of $f$ and $g$ is defined by
\[
(f * g)(t) = \int_0^t f(t-s)g(s)ds.
\]

Definition 1. Let $\alpha > 0$. The $\alpha$-order Riemann-Liouville fractional integral of $u$ is defined by
\[
f^\alpha u(t) = \int_0^t g_{\alpha}(t-s)u(s)ds, \quad t \geq 0.
\]

Also, we define $f^\beta u(t) = u(t)$. Because of the convolution properties, the integral operators $f^\alpha$ satisfy the semigroup law: $f^\alpha f^\beta = f^{\alpha+\beta}$ for all $\alpha, \beta \geq 0$. 

Definition 2. Let $\alpha > 0$. The $\alpha$-order Caputo fractional derivative is defined as

$$D^\alpha \!_t u(t) = \int_0^t \frac{d^n}{ds^n}(t-s) u^{(n)}(s) \, ds,$$

where $n = [\alpha]$.

Definition 3. Let $\alpha > 0$. The $\alpha$-order Riemann-Liouville fractional derivative of $u$ is defined as

$$D^\alpha \!_t u(t) = \frac{d^n}{ds^n} \int_0^t (t-s)^{-\alpha} u(s) \, ds,$$

where $n = [\alpha]$.

We notice that if $\alpha = m \in \mathbb{N}$, then $D^m = D^m = d^m/dt^m$. Throughout this paper we use the notation of $D^m$ and $D^a$ to the $\alpha$-fractional derivative of Caputo and Riemann-Liouville, respectively.

Example 4. If $\alpha, \beta > 0$, then

(i) $I_0^\alpha f^\alpha = (\Gamma(\alpha + 1)/\Gamma(\alpha + \beta + 1)) f^{\alpha+\beta}$,

(ii) $D_0^\alpha f^\alpha = (\Gamma(\alpha + 1)/\Gamma(\alpha + \beta + 1)) f^{\beta+\alpha} = D_0^\alpha \! f^\alpha$.

(iii) $D_0^\alpha e^{at} = \rho^\alpha t^{\alpha-\alpha} e^{\alpha t}(at)$.

We observe that the Riemann-Liouville derivative operator $D^a$ is a left inverse operator of $f^a$ but not a right inverse, that is,

$$D^a f^a u(t) = u(t),$$

$$(f^a D^a) u(t) = u(t) - \sum_{k=0}^{n-1} (g_{a, \alpha} * u)(k)(t) g_{\alpha+1+k, n-a}(t),$$

$n = [\alpha]$. On the other hand, the Caputo derivative operator $D^a_0$ satisfies

$$D^a_0 f^a u(t) = u(t),$$

$$(f^a D^a_0) u(t) = u(t) - \sum_{k=0}^{n-1} u(k)(0) g_{k+1, n-a}(t).$$

If we denote by $f$ (or $\mathcal{L}(f)$) the Laplace transform of $f$, we have the following properties for the fractional derivatives:

$$\mathcal{D}^a u(\lambda) = \lambda^a \hat{u}(\lambda) - \sum_{k=0}^{n-1} (g_{a, \alpha} * \hat{u})(k)(\lambda) \lambda^{n-1-k},$$

$$\mathcal{D}^a_0 u(\lambda) = \lambda^a \hat{u}(\lambda) - \sum_{k=0}^{n-1} (g_{k+1, n-a})(\lambda) \lambda^{n-1-k},$$

where $n = [\alpha]$ and $\lambda \in \mathbb{C}$. For $\alpha, \beta > 0$ and $z \in \mathbb{C}$, the generalized Mittag-Leffler function is defined by

$$e_{\alpha, \beta}(z) = \sum_{k=0}^{\infty} \frac{z^k}{\Gamma(ak + \beta)}.$$
Proposition 6. Let $\alpha, \beta > 0$ and let $\{S_{\alpha,\beta}(t)\}_{t \geq 0} \subset B(X)$ be an $(\alpha, \beta)$-resolvent family generated by $A$. Then the following holds:

1) $S_{\alpha,\beta}(t)x \in D(A)$ and $S_{\alpha,\beta}(t)Ax = AS_{\alpha,\beta}(t)x$ for all $x \in D(A)$ and $t \geq 0$.

2) If $x \in D(A)$ and $t \geq 0$, then

\[ S_{\alpha,\beta}(t)x = g_\beta(t)x + \int_0^t g_\alpha(t-s)AS_{\alpha,\beta}(s)x \, ds. \]  

(23)

3) If $x \in X$ and $t \geq 0$, then

\[ S_{\alpha,\beta}(t)x = g_\beta(t)x + A \int_0^t g_\beta(t-s)S_{\alpha,\beta}(s)x \, ds. \]  

(24)

In particular, $S_{\alpha,\beta}(0) = g_\beta(0)I$.

Finally, we recall the following results.

Theorem 7 (Mazur theorem). If $K$ is a compact subset of a Banach space $X$, then its convex closure $\text{conv}(K)$ is compact.

Theorem 8 (Krasnoselskii theorem). Let $C$ be a closed convex and nonempty subset of a Banach space $X$. Let $Q_1$ and $Q_2$ be two operators such that

(i) if $u, v \in C$, then $Q_1u + Q_2v \in C$,

(ii) $Q_1$ is a mapping contraction,

(iii) $Q_2$ is compact and continuous.

Then, there exists $z \in C$ such that $z = Q_1z + Q_2z$.

Theorem 9 (Schauder’s fixed point theorem). Let $C$ be a nonempty, closed, bounded, and convex subset of a Banach space $X$. Suppose that $\Gamma : C \to C$ is a compact operator. Then $\Gamma$ has at least a fixed point in $C$.

Theorem 10 (Leray-Schauder alternative theorem). Let $C$ be a convex subset of a Banach space $X$. Suppose that $0 \in C$. If $\Gamma : C \to C$ is a completely continuous map, then either $\Gamma$ has a fixed point or the set $\{x \in C : x = \lambda \Gamma(x), \lambda \in (0,1)\}$ is unbounded.

3. Continuity and Compactness of $S_{\alpha,\beta}(t)$

In this section we study, for all $t > 0$, the norm continuity (continuity in $B(X)$) and the compactness of $S_{\alpha,\beta}(t)$ for given $\alpha, \beta > 0$.

Proposition 11. Let $\alpha > 0$ and $1 < \beta \leq 2$. Suppose that $\{S_{\alpha,\beta}(t)\}_{t \geq 0}$ is the $(\alpha, \beta)$-resolvent family of type $(M, \omega)$ generated by $A$. Then the function $t \mapsto S_{\alpha,\beta}(t)$ is continuous in $B(X)$ for all $t > 0$.

Proof. Let $1 < \beta < 2$. Observe that, for all $\text{Re}\, \lambda > 0$,

\[ \mathcal{L}(S_{\alpha,\beta}(t))(\lambda) = \lambda^{\alpha-\beta}(\lambda^\alpha - A)^{-1} \]

(25)

\[ = \frac{1}{\lambda^{\beta-1}}(\lambda - 1)^{-1} \]

(26)

We conclude by the uniqueness of the Laplace transform that $S_{\alpha,\beta}(t) = (g_{\beta-1} * S_{\alpha,1})(t)$, for all $t > 0$. Take $0 < t_0 < t_1$. Then

\[ S_{\alpha,\beta}(t_1) - S_{\alpha,\beta}(t_0) = (g_{\beta-1} * S_{\alpha,1})(t_1) - (g_{\beta-1} * S_{\alpha,1})(t_0) \]

(27)

\[ = \int_{t_0}^{t_1} g_{\beta-1}(t_1 - r) \, S_{\alpha,1}(r) \, dr. \]

Since $\beta > 1$, we have $g_\beta(0) = 0$ and we obtain

\[ \|I_1\| \leq M \int_{t_0}^{t_1} g_{\beta-1}(t_1 - r) \|S_{\alpha,1}(r)\| \, dr \]

\[ \leq Me^{\omega t_1}g_\beta(t_1-t_0), \]

(28)

and therefore $\|I_1\| \to 0$ as $t_1 \to t_0$.

On the other hand,

\[ \|I_2\| \leq \int_0^{t_0} \left| g_{\beta-1}(t_1 - r) - g_{\beta-1}(t_0 - r) \right| \|S_{\alpha,1}(r)\| \, dr \]

\[ \leq Me^{\omega t_1} \int_0^{t_0} \left| g_{\beta-1}(t_1 - r) - g_{\beta-1}(t_0 - r) \right| \, dr. \]

(29)

Since $1 < \beta < 2$ we obtain that the function $r \mapsto g_{\beta-1}(r)$ is decreasing in $[0, \infty)$ and therefore $g_{\beta-1}(r) - g_{\beta-1}(t_1-t_0+r) > 0$, for all $r > 0$, obtaining

\[ \|I_2\| \leq Me^{\omega t_1} \int_0^{t_0} \left| g_{\beta-1}(t_1 - r) - g_{\beta-1}(t_0 - r) \right| \, dr. \]

Therefore, $\|I_2\| \to 0$ as $t_1 \to t_0$. We conclude that $S_{\alpha,\beta}(t)$ is norm continuous, for $1 < \beta < 2$.

On the other hand, if $\beta = 2$, then, by the uniqueness of the Laplace transform, we obtain that

\[ S_{\alpha,2}(t)x = (g_1 * S_{\alpha,1})(t)x = \int_0^t S_{\alpha,1}(r) x \, dr. \]  

(30)
for all $x \in X$. Take $0 < t_0 < t_1$. Then
\[ \|S_{\alpha,2}(t_1)x - S_{\alpha,2}(t_0)x\| \leq \int_{t_0}^{t_1} \|S_{\alpha,1}(r)x\| \, dr \]
\[ \leq Me^\omega t_1 \|x\|(t_1 - t_0), \]
for all $x \in X$. Therefore $\|S_{\alpha,2}(t_1) - S_{\alpha,2}(t_0)\| \to 0$ as $t_1 \to t_0$. □

**Lemma 12.** Suppose that $A$ generates an $(\alpha, \beta)$-resolvent family $(S_{\alpha,\beta}(t))_{t \geq 0}$ of type $(M, \omega)$. If $\gamma > 0$, then $A$ generates an $(\alpha, \beta + \gamma)$-resolvent family of type $(M/\omega, \gamma)$. 

**Proof.** By hypothesis we get, for all $t \geq 0$,
\[ \left\| \left( g_\gamma \ast S_{\alpha,\beta} \right)(t) \right\| \leq M \int_0^t g_\gamma(t - s) e^\omega s \, ds \]
\[ \leq Me^\omega \int_0^t g_\gamma(s) e^{-\omega s} \, ds \]
\[ \leq Me^\omega \int_0^\infty g_\gamma(s) e^{-\omega s} \, ds = \frac{Me^\omega}{\omega}. \]
Therefore $(g_\gamma \ast S_{\alpha,\beta})(t)$ is Laplace transformable and, for all $\lambda > \omega$, we have
\[ \mathcal{L} \left( g_\gamma \ast S_{\alpha,\beta} \right)(\lambda) = \frac{1}{\lambda^\gamma} \lambda^{\alpha - \beta} (\lambda^\gamma - A)^{-1} \]
\[ = \lambda^{\alpha - (\beta + \gamma)} (\lambda^\gamma - A)^{-1} \]
\[ = \mathcal{L} \left( S_{\alpha,\beta + \gamma} \right)(\lambda). \]
We conclude that $A$ generates an $(\alpha, \beta + \gamma)$-resolvent family of type $(M/\omega \gamma, \omega)$. □

**Definition 13.** We say that the resolvent family $(S_{\alpha,\beta}(t))_{t \geq 0} \subset \mathcal{B}(X)$ is compact if, for every $t > 0$, the operator $S_{\alpha,\beta}(t)$ is a compact operator.

In what follows, we will assume that $(S_{\alpha,\beta}(t))_{t \geq 0}$ is strongly continuous for all $\alpha, \beta > 0$.

**Theorem 14.** Let $\alpha > 0$, $1 < \beta \leq 2$, and $(S_{\alpha,\beta}(t))_{t \geq 0}$ be an $(\alpha, \beta)$-resolvent family of type $(M, \omega)$ generated by $A$. Then the following assertions are equivalent:

(i) $S_{\alpha,\beta}(t)$ is a compact operator for all $t > 0$.

(ii) $(\mu - A)^{-1}$ is a compact operator for all $\mu > \omega^{1/\alpha}$.

**Proof.** (i) $\Rightarrow$ (ii) Suppose that the resolvent family $(S_{\alpha,\beta}(t))_{t \geq 0}$ is compact. Let $\lambda > \omega$ be fixed. Then we have
\[ \lambda^{\alpha - \beta} (\lambda^\gamma - A)^{-1} = \int_0^\infty e^{-\lambda t} S_{\alpha,\beta}(t) \, dt, \]
where the integral in the right-hand side exists in the Bochner sense. Because $(S_{\alpha,\beta}(t))_{t \geq 0}$ is continuous in the uniform operator topology (by Proposition II), we conclude that $(\lambda^\gamma - A)^{-1}$ is a compact operator by [30, Corollary 2.3].

(ii) $\Rightarrow$ (i) Let $t > 0$ be fixed. Assume that $1 < \beta < 2$. Since $\beta > 1$, it follows that $g_{\beta - 1} \in L^1_{\omega}(0, \infty)$ and therefore, by [31, Proposition 2.1], we obtain
\[ \lim_{N \to \infty} \frac{1}{2\pi i} \int_{\omega - iN}^{\omega + iN} e^{\lambda t} (g_{\beta - 1} \ast S_{\alpha,1})(\lambda) \, d\lambda \]
\[ = (g_{\beta - 1} \ast S_{\alpha,1})(t) = S_{\alpha,\beta}(t), \]
in $\mathcal{B}(X)$. Therefore,
\[ \frac{1}{2\pi i} \int_{\omega - iN}^{\omega + iN} e^{\lambda t} (\lambda^{-\beta} (\lambda^\gamma - A)^{-1} \right) \, d\lambda = S_{\alpha,\beta}(t), \]
where $\Gamma$ is the path consisting of the vertical line $\{ \omega + is : s \in \mathbb{R} \}$. By hypothesis and [30, Corollary 2.3], we conclude that $S_{\alpha,\beta}(t)$ is compact for all $\alpha > 0$ and $1 < \beta < 2$. Now, we take $\beta = 2$. Observe that in $\mathcal{B}(X)$ we have
\[ \lim_{N \to \infty} \frac{1}{2\pi i} \int_{\omega - iN}^{\omega + iN} e^{\lambda t} (g_1 \ast S_{\alpha,1})(\lambda) \, d\lambda = (g_1 \ast S_{\alpha,1})(t) \]
\[ = S_{\alpha,2}(t), \]
by [31, Proposition 2.1], and as in case $1 < \beta < 2$ we conclude that $S_{\alpha,2}(t)$ is compact for all $t > 0$. □

By Theorem 14 we have the following corollary.

**Corollary 15.** Let $1 < \alpha \leq 2$ and $(S_{\alpha,\alpha}(t))_{t \geq 0}$ be an $(\alpha, \alpha)$-resolvent family of type $(M, \omega)$ generated by $A$. Then the following assertions are equivalent:

(i) $S_{\alpha,\alpha}(t)$ is a compact operator for all $t > 0$.

(ii) $(\mu - A)^{-1}$ is a compact operator for all $\mu > \omega^{1/\alpha}$.

**Proposition 16.** Let $1 < \alpha < 2$, and $(S_{\alpha,1}(t))_{t \geq 0}$ be the $(\alpha, 1)$-resolvent family of type $(M, \omega)$ generated by $A$. Suppose that $S_{\alpha,1}(t)$ is continuous in the uniform operator topology for all $t > 0$. Then the following assertions are equivalent:

(i) $S_{\alpha,1}(t)$ is a compact operator for all $t > 0$.

(ii) $(\mu - A)^{-1}$ is a compact operator for all $\mu > \omega^{1/\alpha}$.

**Proof.** (i) $\Rightarrow$ (ii) Suppose that the resolvent family $(S_{\alpha,1}(t))_{t \geq 0}$ is compact. Let $\lambda > \omega$ be fixed. Then we have
\[ \lambda^{\alpha - 1} (\lambda^\gamma - A)^{-1} = \int_0^\infty e^{-\lambda t} S_{\alpha,1}(t) \, dt, \]
where the integral in the right-hand side exists in the Bochner sense, because \( \{ S_{\alpha,1}(t) \}_{t \geq 0} \) is continuous in the uniform operator topology, by hypothesis. Then, by [30, Corollary 2.3], we conclude that \((\lambda^\alpha - A)^{-1}\) is a compact operator.

(ii) \( \Rightarrow \) (i) Let \( t > 0 \) be fixed. Since \( 1 < \alpha < 2 \), it follows that \( g_{\alpha-3/2} \in L^1_{\text{loc}}[0, \infty) \) and therefore, by [31, Proposition 2.1], we obtain

\[
\lim_{N \to \infty} \frac{1}{2\pi i} \int_{\omega-iN}^{\omega+iN} e^{\lambda t} (g_{\alpha-\alpha} * S_{\alpha,\alpha-1})(\lambda) \, d\lambda = (g_{\alpha-\alpha} * S_{\alpha,\alpha-1})(t) = S_{\alpha,1}(t),
\]

in \( \mathcal{B}(X) \). Therefore,

\[
\frac{1}{2\pi i} \int_{\Gamma} e^{\lambda t} \lambda^{\alpha-1} (\lambda^\alpha - A)^{-1} \, d\lambda = S_{\alpha,1}(t), \quad t > 0,
\]

where \( \Gamma \) is the path consisting of the vertical line \( \omega + is : s \in \mathbb{R} \). By hypothesis and [30, Corollary 2.3], we conclude that \( S_{\alpha,1}(t) \) is compact. \( \square \)

**Proposition 17.** Let \( 3/2 < \alpha < 2 \) and \( \{ S_{\alpha,\alpha-1}(t) \}_{t \geq 0} \) be the \((\alpha, \alpha-1)\)-resolvent family of type \((M, \omega)\) generated by \( A \). Suppose that \( S_{\alpha,\alpha-1}(t) \) is continuous in the uniform operator topology for all \( t > 0 \). Then the following assertions are equivalent:

(i) \( S_{\alpha,\alpha-1}(t) \) is a compact operator for all \( t > 0 \).

(ii) \((\mu - A)^{-1}\) is a compact operator for all \( \mu > \omega^{1/\alpha} \).

**Proof.** (i) \( \Rightarrow \) (ii) It follows as in the proof of Proposition 16.

(ii) \( \Rightarrow \) (i) Let \( t > 0 \) be fixed. Since \( \alpha > 3/2 \), it follows that \( g_{\alpha-3/2} \in L^1_{\text{loc}}[0, \infty) \) and therefore, by [31, Proposition 2.1], we obtain

\[
\lim_{N \to \infty} \frac{1}{2\pi i} \int_{\omega-iN}^{\omega+iN} e^{\lambda t} (g_{\alpha-3/2} * S_{\alpha,1/2})(\lambda) \, d\lambda = (g_{\alpha-3/2} * S_{\alpha,1/2})(t) = S_{\alpha,\alpha-1}(t),
\]

in \( \mathcal{B}(X) \). Therefore,

\[
\frac{1}{2\pi i} \int_{\Gamma} e^{\lambda t} \lambda^{\alpha-1} (\lambda^\alpha - A)^{-1} \, d\lambda = S_{\alpha,\alpha-1}(t),
\]

where \( \Gamma \) is the path consisting of the vertical line \( \omega + is : s \in \mathbb{R} \). By hypothesis and [30, Corollary 2.3], we conclude that \( S_{\alpha,\alpha-1}(t) \) is compact. \( \square \)

The proof of the next result follows similarly to Proposition 16, because for \( 1/2 < \alpha < 1 \) we have

\[
\lim_{N \to \infty} \frac{1}{2\pi i} \int_{\omega-iN}^{\omega+iN} e^{\lambda t} (g_{\alpha-1/2} * S_{\alpha,1/2})(\lambda) \, d\lambda = (g_{\alpha-1/2} * S_{\alpha,1/2})(t) = S_{\alpha,\alpha}(t),
\]

in \( \mathcal{B}(X) \) and \( t > 0 \) by [31, Proposition 2.1].

**Proposition 18.** Let \( 1/2 < \alpha < 1 \) and \( \{ S_{\alpha,\alpha}(t) \}_{t \geq 0} \) be the \((\alpha, \alpha)\)-resolvent family of type \((M, \omega)\) generated by \( A \). Suppose that \( S_{\alpha,\alpha}(t) \) is continuous in the uniform operator topology for all \( t > 0 \). Then, the following assertions are equivalent:

(i) \( S_{\alpha,\alpha}(t) \) is a compact operator for all \( t > 0 \).

(ii) \((\mu - A)^{-1}\) is a compact operator for all \( \mu > \omega^{1/\alpha} \).

**Remark 19.** Let \( \varepsilon_0 > 0 \) be fixed. If \( \varepsilon_0 < \alpha < 1 \), then by [31, Proposition 2.1] we have

\[
\lim_{N \to \infty} \frac{1}{2\pi i} \int_{\omega-iN}^{\omega+iN} e^{\lambda t} (g_{\alpha-\varepsilon_0} * S_{\alpha,\varepsilon_0})(\lambda) \, d\lambda = (g_{\alpha-\varepsilon_0} * S_{\alpha,\varepsilon_0})(t) = S_{\alpha,\alpha}(t),
\]

in \( \mathcal{B}(X) \). Therefore, as is Proposition 18, if \( \alpha > \varepsilon_0 \), where \( \varepsilon_0 > 0 \), \( A \) generates the \((\alpha, \alpha)\)-resolvent family \( \{ S_{\alpha,\alpha}(t) \}_{t \geq 0} \) of type \((M, \omega)\), and \( S_{\alpha,\alpha}(t) \) is norm continuous for all \( t > 0 \), then \( S_{\alpha,\alpha}(t) \) is a compact operator for all \( t > 0 \) if and only if \((\lambda^\alpha - A)^{-1}\) is a compact operator for all \( \lambda > \omega^{1/\alpha} \). The same conclusion holds if \( \varepsilon_0 < \alpha < 2 \), where \( \varepsilon_0 > 1 \) is fixed and \( \{ S_{\alpha,\alpha-1}(t) \}_{t \geq 0} \) is the \((\alpha, \alpha-1)\)-resolvent family of type \((M, \omega)\) generated by \( A \), which is norm continuous for all \( t > 0 \).

### 4. Nonlocal Fractional Cauchy Problems: The Caputo Case

In this section we consider the nonlocal problem for the Caputo fractional derivative

\[
D^\alpha_t u(t) = Au(t) + f(t, u(t)), \quad t \in I = [0, T],
\]

\[
u(0) + p(u) = u_0,
\]

\[
u'(0) + q(u) = u_1,
\]

\( u_0, u_1 \in X, 1 < \alpha < 2, T > 0 \), and \( A \) is a closed linear operator defined on \( X \) which generates the \((\alpha, 1)\)-resolvent family \( \{ S_{\alpha,1}(t) \}_{t \geq 0} \). The nonlinear function \( f : [0, T] \times X \to X \) is continuous and the nonlocal conditions \( p, q : C(I, X) \to C(I, X) \) are also continuous functions. We recall also that the derivative \( D^\alpha_t \) denotes the Caputo fractional derivative.

The mild solution to problem (45) is given by

\[
u(t) = S_{\alpha,1}(t)(u_0 - p(u)) + S_{\alpha,2}(t)(u_1 - q(u)) + \int_0^t S_{\alpha,\alpha}(t-s) f(s, u(s)) \, ds, \quad t \in [0, T].
\]

By the uniqueness of the Laplace transform, it is easy to see that the mild solution to fractional nonlocal problem (45) can be written as
\[ u(t) = S_{\alpha,1}(t)(u_0 - p(u)) \\
+ (g_1 \ast S_{\alpha,1})(t)(u_1 - q(u)) \\
+ \int_0^t (g_{\alpha-1} \ast S_{\alpha,1})(t-s) f(s,u(s)) \, ds, \]  
for all \( t \in [0, T] \).

We assume the following:

(H1) The function \( f \) satisfies the Carathéodory condition; that is, \( f(\cdot, u) \) is strongly measurable for each \( u \in X \) and \( f(t, \cdot) \) is continuous for each \( t \in I = [0, T] \).

(H2) There exists a continuous function \( \mu : I \to \mathbb{R}_+ \) such that

\[ \|f(t,u)\| \leq \mu(t)\|u\|, \quad \forall t \in I, \ u \in C(I, X). \]  

(H3) The functions \( p, q : C(I, X) \to C(I, X) \) are continuous and there exist \( L_p, L_q > 0 \) such that

\[ \|p(u) - p(v)\| < L_p\|u - v\|, \]
\[ \|q(u) - q(v)\| < L_q\|u - v\|, \]  

\[ \forall u, v \in C(I, X). \]

We have the following existence results.

**Theorem 20.** Let \( 1 < \alpha < 2 \). Let \( A \) be the generator of an \((\alpha, 1)\)-resolvent family \( \{S_{\alpha,1}(t)\}_{t \geq 0} \) of type \((M, \omega)\). Suppose that \((A^\alpha - A)^{-1}\) is compact for all \( \lambda > \omega^{1/\alpha} \). If \((M e^{\omega T}/\omega^{\alpha-1})\|\mu\|_{\infty, T} < 1 \) and \((M e^{\omega T} L_p + (M/\omega) e^{\omega T} L_q) < 1 \), then, under assumptions (H1)-(H3), problem (45) has at least one mild solution.

**Proof.** Let \( B_r := \{u \in C(I, X) : \|u\| \leq r\} \), where

\[ r = \frac{Me^{\omega T}(\|u_0\| + \|p(u)\|) + (M/\omega)e^{\omega T}(\|u_1\| + \|q(u)\|)}{1 - (Me^{\omega T}/\omega^{\alpha-1})\|\mu\|_{\infty, T}}. \]  

On \( B_r \) we define the operators \( \Gamma_1, \Gamma_2 \) by

\[ (\Gamma_1 u)(t) := S_{\alpha,1}(t)(u_0 - p(u)) \\
+ (g_1 \ast S_{\alpha,1})(t)(u_1 - q(u)), \quad t \in [0, T], \]  

\[ (\Gamma_2 u)(t) := \int_0^t (g_{\alpha-1} \ast S_{\alpha,1})(t-s) f(s,u(s)) \, ds, \quad t \in [0, T], \]  

and \( u \in B_r \). We shall prove that \( \Gamma = \Gamma_1 + \Gamma_2 \) has at least one fixed point by the Krasnoselskii fixed point theorem. We will consider several steps in the proof.

**Step 1.** We will see that if \( u, v \in B_r \), then \( \Gamma_1 u + \Gamma_2 v \in B_r \). In fact, by Lemma 12 we have

\[ \|\Gamma_1 u(t) + \Gamma_2 v(t)\| \leq \|S_{\alpha,1}(t)(u_0 - p(u))\| \\
+ \|((g_1 \ast S_{\alpha,1})(t)(u_1 - q(u))\| \\
+ \int_0^t \|S_{\alpha,1}(t-s) f(s,u(s))\| \, ds, \]

\[ \leq Me^{\omega T}(\|u_0\| + \|p(u)\|) + (M/\omega)e^{\omega T}(\|u_1\| + \|q(u)\|) \\
+ M\|e^{\omega T}\|\|u_1\| + \|q(u)\| \\
+ \int_0^t \|S_{\alpha,1}(t-s) f(s,u(s))\| \, ds, \]

\[ \leq Me^{\omega T}(\|u_0\| + \|p(u)\|) + (M/\omega)e^{\omega T}(\|u_1\| + \|q(u)\|) \\
+ M\|e^{\omega T}\|\|u_1\| + \|q(u)\| + \int_0^t \|u_1\| + \|q(u)\| \, ds. \]

Hence \( \Gamma_1 u + \Gamma_2 v \in B_r \) for all \( u, v \in B_r \).

**Step 2.** \( \Gamma_1 \) is a contraction on \( B_r \). In fact, if \( u, v \in B_r \), then

\[ \|\Gamma_1 u(t) - \Gamma_1 v(t)\| \leq \|S_{\alpha,1}(t)(p(u) - p(v))\| \\
+ \|((g_1 \ast S_{\alpha,1})(t)(q(u) - q(v))\| \\
+ \int_0^t \|S_{\alpha,1}(t-s) f(s,u(s))\| \, ds, \]

\[ \leq Me^{\omega T} L_p\|u - v\| + (M/\omega)e^{\omega T} L_q\|u - v\| + \int_0^t e^{\omega s}\|\mu(s)v(s)\| \, ds, \]

\[ \leq \left(Me^{\omega T} L_p + (M/\omega)e^{\omega T} L_q\right)\|u - v\| + \int_0^t e^{\omega s}\|\mu(s)v(s)\| \, ds, \]

Since \((Me^{\omega T} L_p + (M/\omega)e^{\omega T} L_q) < 1\), we conclude that \( \Gamma_1 \) is a contraction.
Step 3. $\Gamma_2$ is completely continuous.

Firstly, we prove that $\Gamma_2$ is continuous on $B_r$. Let $u_n, u \in B_r$ such that $u_n \to u$ in $B_r$. By Lemma 12 we get

$$
\|\Gamma_2 u_n(t) - \Gamma_2 u(t)\| \leq \int_0^t \|g_{t-1} * S_{\alpha,1}(t-s)\| ds \leq \frac{Me^{\omega t}}{\alpha-1}.
$$

We notice that the function $s \mapsto \mu(s)$ is integrable on $I$. By Lebesgue's dominated convergence theorem, we have

$$
\lim_{n \to \infty} \int_0^t \|g_{t-1} * S_{\alpha,1}(t-s)\| ds = \int_0^t \|g_{t-1} * S_{\alpha,1}(t-s)\| ds.
$$

Now, we will prove that $\Gamma_2 u(n) : u \in B_r$ is relatively compact. By the Ascoli-Arzela theorem, we need to show that the family $\{\Gamma_2 u(n) : u \in B_r\}$ is uniformly bounded and equicontinuous, and the set $\{\Gamma_2 u(n) : u \in B_r\}$ is relatively compact in $X$ for each $t \in [0, T]$. In fact, for each $u \in B_r$, we have (as in Step 3) that $\|\Gamma_2 u(n)\| \leq (rMe^{\omega t}/\alpha-1)\|\mu\|_{\infty}$ and therefore $\{\Gamma_2 u(n) : u \in B_r\}$ is uniformly bounded.

In order to prove the equicontinuity, let $u \in B_r$, and take $0 \leq t_2 < t_1 \leq T$. Observe that

$$
\|\Gamma_2 u(t_1) - \Gamma_2 u(t_2)\| \leq \int_{t_2}^{t_1} \|g_{t-1} * S_{\alpha,1}(t-s)\| ds \leq \frac{Me^{\omega t}}{\alpha-1}.
$$

Observe that, for $I_1$, by Lemma 12 we have

$$
I_1 \leq \frac{Me^{\omega t}}{\alpha-1} \int_{t_2}^{t_1} e^{-\omega s} \mu(s) \|u(s)\| ds \leq \frac{Mr e^{\omega t}}{\alpha-1} \|\mu\|_{\infty} (t_1 - t_2),
$$

and therefore $\lim_{t_1 \to t_2} I_1 = 0$. For $I_2$, we have

$$
I_2 \leq \int_0^t \|g_{t-1} * S_{\alpha,1}(t-s)\| ds \leq \int_0^t \|g_{t-1} * S_{\alpha,1}(t-s)\| ds + \int_0^t \|g_{t-1} * S_{\alpha,1}(t-s)\| ds = \int_0^t \|g_{t-1} * S_{\alpha,1}(t-s)\| ds = I_1.
$$

and, by Lemma 12, $(g_{t-1} * S_{\alpha,1}(t-s)) = S_{\alpha,1}(t-s) = 0$ for all $t \geq 0$. Moreover, by Proposition 11 we have that $S_{\alpha,1}(t) = \mu(t) \in L^1([t-\varepsilon, t], \mathbb{R})$, and the hypothesis implies the compactness of $(g_{t-1} * S_{\alpha,1}(t-s)) = S_{\alpha,1}(t-s) = 0$ for all $t > 0$ (by Lemma 12 and Theorem 14) and therefore the set $\mathcal{K} = \{\gamma_{t-1} * S_{\alpha,1}(t-s) f(s, u(s)) : u \in B_r, 0 \leq s \leq t \leq \varepsilon\}$ is compact for all $T > 0$. Then $\text{conv} (\mathcal{K})$ is also a compact set by Theorem 7. By using the mean-value theorem for Lebesgue integrals (see [32, Corollary 8, page 48]), we obtain that

$$
\|\Gamma_2 u(t)\| \leq \int_{t-\varepsilon}^t \|g_{t-1} * S_{\alpha,1}(t-s) f(s, u(s))\| ds.
$$

Therefore, the set $H(t) = \{\gamma_{t} u(t) : u \in B_r\}$ is relatively compact in $X$ for all $T > 0$. Now, observe that

$$
\|\Gamma_2 u(t) - \Gamma_2 u(t)\| \leq \int_{t-\varepsilon}^t \|g_{t-1} * S_{\alpha,1}(t-s) f(s, u(s))\| ds \leq \frac{Mr e^{\omega t}}{\alpha-1} \|\mu\|_{\infty} (t_1 - t_2),
$$

Since the function $s \mapsto e^{-\omega s} \mu(s)$ belongs to $L^1([t-\varepsilon, t], \mathbb{R}_+)$, we conclude by the Lebesgue dominated convergence theorem that

$$
\lim_{\varepsilon \to 0} \|\Gamma_2 u(t) - \Gamma_2 u(t)\| = 0.
$$
Therefore the set \{Γ₂𝑢(𝑡) : 𝑢 ∈ 𝐵𝑟\} is relatively compact in 𝑋 for each 𝑡 ∈ (0, 𝑇]. By the Ascoli-Arzela theorem, the set \{Γ₂𝑢 : 𝑢 ∈ 𝐵𝑟\} is relatively compact. We conclude that Γ₂ is a completely continuous operator. Hence, by Krasnoselskii Theorem 8 we have that Γ = Γ₁ + Γ₂ has a fixed point on B₁, which means that nonlocal problem (45) has a mild solution and the proof of the theorem is finished.

The proof of the following result uses the Schauder fixed point theorem. We notice that here we will assume that \( S_{\alpha,1}(t) \) is continuous in the uniform operator topology for all \( t > 0 \). Moreover, we have a weaker condition on the parameters \( M, \omega, \) and \( T \).

**Theorem 21.** Let \( 1 < \alpha < 2 \). Let \( A \) be the generator of an \((\alpha, 1)\)-resolvent family \( \{S_{\alpha,1}(t)\}_{t \geq 0} \) of type \((M, \omega)\). Suppose that \((\lambda^\alpha - A)\) is compact for all \( \lambda > 1/\alpha \), \( S_{\alpha,1}(t) \) is continuous in the uniform operator topology for all \( t > 0 \), and \( Me^{\omega T}\|\mu\|_{\infty} T < 1 \). Then, under assumptions (HI)-(H3), problem (45) has at least one mild solution.

**Proof.** We define the operator \( \Gamma : C(I, X) \rightarrow C(I, X) \) by

\[
\Gamma u(t) = S_{\alpha,1}(t) [u_0 - p(u)] + \frac{g_1 * S_{\alpha,1}(t)}{(t - s)} f(s, u(s)) ds \]

for all \( t \in I = [0, T] \).

Choose

\[
r = \frac{Me^{\omega T}\|u_0\| + \|p(u)\| + (M/\omega) e^{\omega T}\left(\|u_t\| + \|q(u)\|\right)}{1 - (Me^{\omega T}\|u_0\| + \|p(u)\| + (M/\omega) e^{\omega T}\left(\|u_t\| + \|q(u)\|\right))}.
\]

Let \( B_r = \{u \in C(I, X) : \|u\| \leq r\} \). We shall prove that \( \Gamma B_r \) has at least one fixed point by the Schauder fixed point theorem. As in the proof of Theorem 20 it is easy to see that \( \Gamma \) sends \( B_r \) into \( B_r \), and \( \Gamma : B_r \rightarrow B_r \) is a continuous operator.

We claim that \( \{\Gamma u : u \in B_r\} \) is relatively compact.

Indeed, as in the proof of Theorem 20, it is easy to see that \( \{\Gamma u : u \in B_r\} \) is uniformly bounded. On the other hand, to see the equicontinuity, let \( u \in B_r \), and take \( t_1, t_2 \in I \) with \( 0 \leq t_2 < t_1 \leq T \). We have

\[
\|\Gamma u(t_1) - \Gamma u(t_2)\| \leq \left\| S_{\alpha,1}(t_1) - S_{\alpha,1}(t_2) \right\| (u_0 - p(u)) + \left\| (g_1 * S_{\alpha,1})(t_1) - (g_1 * S_{\alpha,1})(t_2) \right\|

\cdot (u_1 - q(u)) + \int_{t_1}^{t_2} \left\| (g_{\alpha-1} * S_{\alpha,1})(t_1 - s) \right\| ds + \int_{t_1}^{t_2} \left\| (g_{\alpha-1} * S_{\alpha,1})(t_2 - s) \right\| ds - (g_1 * S_{\alpha,1})(t_2 - s) f(s, u(s)) ds + I_3 + I_4.
\]

Observe that for \( I_1 \) we have

\[
I_1 \leq \left\| S_{\alpha,1}(t_1) - S_{\alpha,1}(t_2) \right\| \left\| (u_0 - g(u)) \right\|.
\]

By hypothesis, using the norm continuity of \( S_{\alpha,1}(t) \), we obtain that \( \lim_{t_1 \to t_2} I_1 = 0 \).

Lemma 12 implies \((g_1 * S_{\alpha,1})(t) = S_{\alpha,2}(t)\) for all \( t \geq 0 \) and by Proposition 11 we have that \( (g_1 * S_{\alpha,1})(t) \) is continuous in \( \mathcal{B}(X) \), and hence

\[
I_2 \leq \left\| (g_1 * S_{\alpha,1})(t_1) - (g_1 * S_{\alpha,1})(t_2) \right\| (u_0 - g(u)) \]

\[
\to 0,
\]

as \( t_1 \to t_2 \). On the other hand, \( I_3, I_4 \to 0 \) as \( t_1 \to t_2 \) as in the proof of Step 3 in Theorem 20. Therefore, the set \{\Gamma u : u \in B_r\} is equicontinuous.

Finally, we will prove that \( \{\Gamma u(t) : u \in B_r\} \) is relatively compact for all \( t \in [0, T] \). Clearly, \( \{\Gamma u(0) : u \in B_r\} \) is relatively compact. Now, we take \( t > 0 \). For each \( 0 < \varepsilon < t \), we define the operator

\[
(\Gamma u)(t) = S_{\alpha,1}(\varepsilon) \int_0^{t-\varepsilon} (g_{\alpha-1} * S_{\alpha,1})(t - s - \varepsilon) f(s, u(s)) ds.
\]

The hypothesis and Proposition 16 show that \( S_{\alpha,1}(t) \) is compact for all \( t > 0 \) and therefore the set \( H_t(\varepsilon) = \{\Gamma u(t) : u \in B_r\} \) is relatively compact in \( \mathcal{B}(X) \) for all \( \varepsilon > 0 \). Now, observe that

\[
\left\| S_{\alpha,1}(\varepsilon) \int_0^{t-\varepsilon} (g_{\alpha-1} * S_{\alpha,1})(t - s - \varepsilon) f(s, u(s)) ds \right\|

\leq r \int_0^{t-\varepsilon} \left\| S_{\alpha,1}(\varepsilon) (g_1 * S_{\alpha,1})(t - s - \varepsilon) \right\| \mu(s) ds.
\]

By Proposition 11, \((g_1 * \cdot S_{\alpha,1})(t)\) is norm continuous for all \( t > 0 \) and therefore

\[
\left\| S_{\alpha,1}(\varepsilon) (g_1 * \cdot S_{\alpha,1})(t - s - \varepsilon) \right\| \to 0, \quad \varepsilon \to 0.
\]

On the other hand, since

\[
\left\| S_{\alpha,1}(\varepsilon) (g_{\alpha-1} * \cdot S_{\alpha,1})(t - \varepsilon) - (g_{\alpha-1} * \cdot S_{\alpha,1})(t - \varepsilon) \right\|

\leq \frac{M\varepsilon e^{2\omega T}}{\alpha^{\omega-1}} e^{-\omega(t+\varepsilon)} + \frac{Me^{\omega T}}{\alpha^{\omega-1}} e^{-\omega}
\]

and the function \( s \mapsto (M\varepsilon e^{2\omega T}/\alpha^{\omega-1}) e^{-\omega(t+\varepsilon)} + (Me^{\omega T}/\alpha^{\omega-1}) e^{-\omega} \) belongs to \( L^1(I, \mathbb{R}_+) \), we conclude by the Lebesgue dominated convergence theorem that

\[
\lim_{\varepsilon \to 0} \left\| S_{\alpha,1}(\varepsilon) \int_0^{t-\varepsilon} (g_{\alpha-1} * S_{\alpha,1})(t - s - \varepsilon) f(s, u(s)) ds \right.

\left. - \int_0^{t-\varepsilon} (g_{\alpha-1} * S_{\alpha,1})(t - s) f(s, u(s)) ds \right\| = 0.
\]
As in the proof of [24, Theorem 4.1], we get
\[
\lim_{\varepsilon \to 0} \left\| S_{\alpha,1}(\varepsilon) \right\| \left( \int_0^t (g_{\alpha-1} * S_{\alpha,1})(t-s) f(s, u(s)) \, ds \right) = 0,
\]
and therefore the set \( \{ \int_0^t (g_{\alpha-1} * S_{\alpha,1})(t-s) f(s, u(s)) \, ds : u \in B \} \) is relatively compact for all \( t \in (0, T] \). The compactness of \( S_{\alpha,1}(t) \) and \( (g_1 * S_{\alpha,1})(t) = S_{\alpha,2}(t) \) (by Lemma 12 and Theorem 14) imply that \( \{ u(t) : u \in B \} \) is relatively compact in \( X \) for each \( t \in (0, T] \). By the Ascoli-Arzela theorem, the set \( \{ \Gamma u : u \in B \} \) is relatively compact. We conclude that \( \Gamma \) is a compact operator on \( B \), Hence, by Schauder Theorem 9 we have that \( \Gamma \) has a fixed point on \( B \), and therefore nonlocal problem (45) has a mild solution.

**Remark 22.** We notice that the norm continuity of \( S_{\alpha,1}(t) \) for \( 0 < \alpha < 1 \) and \( t > 0 \) follows, for example, if \( S_{\alpha,1}(t) \) is analytic (see [24, Lemma 3.8]) or if \( A \) is an almost sectorial operator (see [23, Theorem 3.2]).

Now, we consider the nonlocal problem for the Caputo fractional derivative
\[
D^\alpha_t u(t) = Au(t) + f(t, u(t)), \quad t \in [0, T],
\]
\[
_{0} D^\alpha_t u(0) + p(u) = u_0,
\]
where \( u_0 \in X, 1/2 < \alpha < 1, T > 0, \) and \( A \) is a closed linear operator defined on \( X \) which generates the \((\alpha, \alpha)\)-resolvent family \( \{ S_{\alpha,\alpha}(t) \}_{t \geq 0} \).

The mild solution to problem (74) is given by
\[
u(t) = S_{\alpha,1}(t)(u_0 - p(u)) + \int_0^t S_{\alpha,2}(t-s) f(s, u(s)) \, ds, \quad t \in [0, T].
\]

It is easy to see (by using the uniqueness of the Laplace transform) that the mild solution to problem (74) can be also written as
\[
u(t) = (g_{1-\alpha} * S_{\alpha,\alpha})(t)(u_0 - p(u)) + \int_0^t S_{\alpha,\alpha}(t-s) f(s, u(s)) \, ds, \quad t \in [0, T].
\]

The proof of the following result follows similarly to Theorem 20 and therefore we omit it.

**Theorem 23.** Let \( 1/2 < \alpha < 1 \). Let \( A \) be the generator of an \((\alpha, \alpha)\)-resolvent family \( \{ S_{\alpha,\alpha}(t) \}_{t \geq 0} \) of type \((M, \omega)\). Suppose that \( (A^\alpha - A)^{-1} \) is compact for all \( \lambda > \omega^{1/\alpha} \), and \( S_{\alpha,\alpha}(t) \) is continuous in the uniform operator topology for all \( t > 0 \). If \( |Me^{\omega t}| \|\mu\|_\infty T < 1 \) and \( (M/\omega)e^{\omega t}L_p < 1 \), then, under assumptions (H1)–(H3), problem (74) has at least one mild solution.

**5. Nonlocal Fractional Cauchy Problems:**
**The Riemann-Liouville Case**

In this section we consider the nonlocal problem for the Riemann-Liouville fractional derivative
\[
D^\alpha u(t) = Au(t) + f(t, u(t)), \quad t \in [0, T],
\]
\[
(g_{2-\alpha} * u)(0) + p(u) = u_0,
\]
\[
(g_{2-\alpha} * u)(0) + q(u) = u_1,
\]
where \( u_0, u_1 \in X, 1 < \alpha < 2, \) and \( A \) is a closed linear operator defined on \( X \). Assume that \( A \) generates an \((\alpha, \alpha - 1)\)-resolvent family given by \( \{ S_{\alpha,\alpha-1}(t) \}_{t \geq 0} \). Taking Laplace transform in (77) we obtain by (14) that
\[
u(t) = S_{\alpha,\alpha-1}(t)(u_0 - p(u)) + S_{\alpha,\alpha}(t)(u_1 - q(u)) + \int_0^t S_{\alpha,\alpha}(t-s) f(s, u(s)) \, ds, \quad t \in [0, T].
\]

The uniqueness of the Laplace transform implies that the mild solution to problem (77) is also given by
\[
u(t) = S_{\alpha,\alpha-1}(t)(u_0 - p(u)) + (g_1 * S_{\alpha,\alpha-1})(t)(u_1 - q(u)) + \int_0^t (g_1 * S_{\alpha,\alpha-1})(t-s) f(s, u(s)) \, ds,
\]
for all \( t \in [0, T] \).

**Theorem 24.** Let \( 1 < \alpha < 2 \). Let \( A \) be the generator of an \((\alpha, \alpha - 1)\)-resolvent family \( \{ S_{\alpha,\alpha-1}(t) \}_{t \geq 0} \) of type \((M, \omega)\). Assume that the resolvent \((X^\alpha - A)^{-1} \) is compact for all \( \lambda > \omega^{1/\alpha} \). If \( |Me^{\omega T}L_p + (M/\omega)e^{\omega T}L_p| < 1 \) and \( (Me^{\omega T}/\omega)\|\mu\|_\infty T < 1 \), then, under assumptions (H1)–(H3), problem (77) has at least one mild solution.

**Proof.** Let \( B_r = \{ u \in C(I, X) : \|u\| \leq r \} \), where
\[
r := \frac{|Me^{\omega T}\|\mu\|_\infty T + \|p(u)\| + (M/\omega)e^{\omega T}\|\mu\|_\infty T + \|q(u)\|}{1 - (Me^{\omega T}/\omega)\|\mu\|_\infty T}.
\]

On \( B_r \) we define the operators \( \Gamma_1, \Gamma_2 \) by
\[
(\Gamma_1 u)(t) = S_{\alpha,\alpha-1}(t)(u_0 - p(u)) + (g_1 * S_{\alpha,\alpha-1})(t)(u_1 - q(u)), \quad t \in [0, T],
\]
\[
(\Gamma_2 u)(t) = \int_0^t (g_1 * S_{\alpha,\alpha-1})(t-s) f(s, u(s)) \, ds, \quad t \in [0, T],
\]
and \( u \in B_r \). We shall prove that \( \Gamma = \Gamma_1 + \Gamma_2 \) has at least one fixed point by the Krasnoselskii fixed point theorem. We will consider several steps in the proof.

**Step 1.** We will see that if \( u, v \in B_r \), then \( \Gamma_1 u + \Gamma_2 v \in B_r \). In fact, by Lemma 12 we have

\[
\| (\Gamma_1 u)(t) - (\Gamma_2 v)(t) \| \\
\leq \| S_{\alpha,\alpha-1}(t) \| \| u_0 - p(u) \| \\
+ \| (g_1 \ast S_{\alpha,\alpha-1})(t) \| \| u_1 - q(u) \|
+ \int_0^t \| g_1 \ast S_{\alpha,\alpha-1}(t-s) \| f(s,v(s)) \| ds \\
\leq Me^{\omega t} (\| u_0 \| + \| p(u) \|) + \frac{M e^{\omega t}}{\omega} \| q(u) \|
+ \int_0^t e^{-\omega s} \mu(s) \| ds \\
\leq Me^{\omega T} (\| u_0 \| + \| p(u) \|) \\
+ \frac{M e^{\omega T}}{\omega} \| q(u) \| + \frac{M e^{\omega T}}{\omega} \| \mu \|_\infty T
= r.
\]

Hence \( \Gamma_1 u + \Gamma_2 v \in B_r \) for all \( u, v \in B_r \).

**Step 2.** \( \Gamma_1 \) is a contraction on \( B_r \). In fact, if \( u, v \in B_r \), then

\[
\| \Gamma_1 u(t) - \Gamma_1 v(t) \| \\
\leq \| S_{\alpha,\alpha-1}(t) \| \| p(u) - p(v) \| \\
+ \| (g_1 \ast S_{\alpha,\alpha-1})(t) \| \| q(u) - q(v) \|
\leq Me^{\omega T} L_p \| u - v \| + \frac{M e^{\omega T}}{\omega} \| L_q \| \| u - v \|
\leq \left( \frac{M e^{\omega T} L_p + \frac{M e^{\omega T}}{\omega} L_q}{\omega} \right) \| u - v \|.
\]

Since \( (M e^{\omega T} L_p + \frac{M e^{\omega T}}{\omega} L_q) < 1 \), we conclude that \( \Gamma_1 \) is a contraction.

**Step 3.** \( \Gamma_2 \) is completely continuous.

As in the proof of Theorem 20 it is easy to see that \( \Gamma_2 \) is a continuous operator and the set \( \{ \Gamma_2 u : u \in B_r \} \) is uniformly bounded. To prove the equicontinuity, let \( u \in B_r \), and take \( 0 \leq t_2 < t_1 \leq T \). Observe that

\[
\| \Gamma_2 u(t_1) - \Gamma_2 u(t_2) \| \\
\leq \| \int_{t_2}^{t_1} \left( (g_1 \ast S_{\alpha,\alpha-1})(t_1 - s) - (g_1 \ast S_{\alpha,\alpha-1})(t_2 - s) \right) f(s,u(s)) \| ds \\
+ I_2
\]

To estimate \( I_1 \) we notice that

\[
I_1 \leq \frac{Me^{\omega T}}{\omega} \int_{t_2}^{t_1} e^{-\omega s} \| \mu \|_\infty \| u(s) \| ds
\]

and therefore \( \lim_{t_1 \to t_2} I_1 = 0 \). For \( I_2 \) we have

\[
I_2 \leq \int_0^{t_2} \| (g_1 \ast S_{\alpha,\alpha-1})(t_1 - s) - (g_1 \ast S_{\alpha,\alpha-1})(t_2 - s) \| f(s,u(s)) \| ds \\
\leq \int_0^{t_2} \mu(s) \| (g_1 \ast S_{\alpha,\alpha-1})(t_1 - s) - (g_1 \ast S_{\alpha,\alpha-1})(t_2 - s) \| ds \\
\leq \int_0^{t_2} \mu(s) \| (g_1 \ast S_{\alpha,\alpha-1})(t_1 - s) - (g_1 \ast S_{\alpha,\alpha-1})(t_2 - s) \| ds.
\]

Observe that

\[
\| (g_1 \ast S_{\alpha,\alpha-1})(t_1 - s) - (g_1 \ast S_{\alpha,\alpha-1})(t_2 - s) \| \\
\leq 2 \frac{Me^{\omega T}}{\omega} \mu(\cdot) \| (g_1 \ast S_{\alpha,\alpha-1})(t_2 - s) \| \leq 2 \frac{Me^{\omega T}}{\omega} \mu(\cdot) \in L^1(I, \mathbb{R}),
\]

and, by Lemma 12, \( (g_1 \ast S_{\alpha,\alpha-1})(t) = S_{\alpha,\alpha}(t) \) for all \( t \geq 0 \). Moreover, by Proposition 11 we have that \( S_{\alpha,\alpha}(t) \) is norm continuous and therefore if \( t_1 \to t_2 \), then \( (g_1 \ast S_{\alpha,\alpha-1})(t_1 - s) - (g_1 \ast S_{\alpha,\alpha-1})(t_2 - s) \to 0 \) in \( \mathcal{B}(X) \). We obtain by Lebesgue’s dominated convergence theorem that \( \lim_{t_1 \to t_2} I_2 = 0 \). Therefore, \( \{ \Gamma_2 u : u \in B_r \} \) is an equicontinuous family. Finally, the compactness of \( (g_1 \ast S_{\alpha,\alpha-1})(t) = S_{\alpha,\alpha}(t) \) for all \( t > 0 \) (by Lemma 12 and Theorem 14) implies that \( \{ \Gamma_2 u : u \in B_r \} \) is relatively compact in \( X \) for each \( t \in [0,T] \) (as in the proof of Theorem 20). We conclude that \( \Gamma_2 \) is a completely continuous operator and, by the Krasnoselskii theorem, the operator \( \Gamma = \Gamma_1 + \Gamma_2 \) has a fixed point on \( B_r \), which means that nonlocal problem (77) has at least one mild solution.

In the next result, we consider a weaker condition on the parameters \( M, \omega \), and \( T \). However, we need to assume here the norm continuity of \( S_{\alpha,\alpha-1}(t) \) for \( 3/2 < \alpha < 2 \).

**Theorem 25.** Let \( 3/2 < \alpha < 2 \). Let \( A \) be the generator of an \((\alpha,\alpha-1)-\)resolvent family \( \{ S_{\alpha,\alpha-1}(t) \}_{t \geq 0} \) of type \((M, \omega)\). Assume that \((\lambda^\alpha - A)^{-1} \) is compact for all \( \lambda > \omega^{\frac{1}{\alpha}} \) and \( S_{\alpha,\alpha-1}(t) \) is continuous in the uniform operator topology for all \( t > 0 \). If \( (Me^{\omega T}/\omega) \| \mu \|_\infty T < 1 \), then, under assumptions (H1)–(H3), problem (77) has at least one mild solution.
Proof. On $B$, we define the operator
\[
\Gamma u(t) = S_{\alpha,1}(t)(u_0 - p(u)) + (g_1 * S_{\alpha,1})(t)(u_1 - q(u)) + \int_0^t (g_1 * S_{\alpha,1})(t-s)f(s,u(s))\,ds,
\]
where $t \in [0,T]$ and
\[
r = \frac{Me^{\omega T}(\|u_0\| + \|p(u)\|) + (M/\omega)Me^{\omega T}(\|u_1\| + \|q(u)\|)}{1 - (Me^{\omega T}/\omega)\|\mu\|_\infty T}.
\]

The proof follows the same lines of Theorem 21. We give here only the details on the relative compactness of $\{\Gamma u(t) : u \in B\}$ in $X$ for each $t \in [0,T]$. Theorem 14 implies that $(g_1 * S_{\alpha,1})(t) = S_{\alpha,1}(t)$ is compact for all $t > 0$ and therefore the set $\{\int_0^t (g_1 * S_{\alpha,1})(t-s)f(s,u(s))\,ds : u \in B\}$ is relatively compact for all $t \in [0,T]$ (as in the proof of Theorem 20). On the other hand, the hypothesis and Proposition 17 imply that $S_{\alpha,1}(t)$ is compact for all $t > 0$ and thus the set $\{\Gamma u(t) : u \in B\}$ is relatively compact for all $t \in [0,T]$. The existence of a fixed point to $\Gamma$, and therefore of a mild solution to problem (77), follows from the Schauder theorem.

Now we discuss the existence of mild solutions to the nonlocal fractional Cauchy problem for the Riemann-Liouville fractional derivative in case $0 < \alpha < 1$:
\[
D^\alpha u(t) = Au(t) + f(t,u(t)), \quad t \in [0,T],
\]
\[
(g_1 * u)(0) + p(u) = u_0,
\]
where $u_0 \in X$ and $A$ is a closed linear operator defined on $X$. We assume that $A$ generates an $(\alpha,1)$-resolvent family given by $\{S_{\alpha,1}(t)\}_{t \geq 0}$. By using the Laplace transform in (90), it is easy to see that
\[
u(t) = S_{\alpha,1}(t)(u_0 - p(u)) + \int_0^t S_{\alpha,1}(t-s)f(s,u(s))\,ds, \quad t \in [0,T].
\]

\[\text{Theorem 26.} \text{ Let } 1/2 < \alpha < 1. \text{ Let } A \text{ be the generator of an } (\alpha,1)\text{-resolvent family } \{S_{\alpha,1}(t)\}_{t \geq 0} \text{ of type } (M,\omega). \text{ Assume that } (\lambda^\alpha - A)^{-1} \text{ is compact for all } \lambda > \omega^\alpha, \text{ and } S_{\alpha,1}(t) \text{ is continuous in the uniform operator topology for all } t > 0. \text{ If } Me^{\omega T}\|\mu\|_\infty T < 1 \text{ and } Me^{\omega T}\|\mu\|_p < 1, \text{ then, under assumptions (H1)-(H3), problem (90) has at least one mild solution.}
\]

Proof. Let
\[
r = \frac{Me^{\omega T}(\|u_0\| + \|p(u)\|)}{1 - Me^{\omega T}\|\mu\|_\infty T}.
\]
If we define on $B$, the operators $\Gamma_1, \Gamma_2$ by
\[
\Gamma_1 u(t) = S_{\alpha,1}(t)[u_0 - p(u)], \quad t \in [0,T],
\]
\[
\Gamma_2 u(t) = \int_0^t S_{\alpha,1}(t-s)f(s,u(s))\,ds, \quad t \in [0,T],
\]
for $u \in B$, then, as in the proof of the previous theorems, it is easy to see that if $u, v \in B$, then $\Gamma_1 u + \Gamma_2 v \in B$, and $\Gamma_1$ is a contraction on $B$. Moreover, $\Gamma_2$ is continuous on $B$, $\{\Gamma_2 u : u \in B\}$ is uniformly bounded, and $\{\Gamma_2 u : u \in B\}$ is an equicontinuous family. Finally, by the compactness of $S_{\alpha,1}(t)$ (see Proposition 18) and by using a similar method as we did in the proof of Theorem 20 (Step 3), we prove that $H(t) = \{\Gamma_2 u(t) : u \in B\}$ is relatively compact in $X$ for each $t \in [0,T]$. Thus, by the Ascoli-Arzela theorem, the set $\{\Gamma_2 u : u \in B\}$ is relatively compact and hence $\Gamma_2$ is a completely continuous operator. By the Krasnoselskii theorem, we conclude that $\Gamma = \Gamma_1 + \Gamma_2$ has a fixed point on $B$, and therefore nonlocal problem (90) has at least one mild solution.

6. Applications

In this section, we give some applications. As consequence of the previous results, we have the following results.

Consider the semilinear problem
\[
D^\alpha u(t) = Au(t) + f(t,u(t)), \quad t \in I \subset [0,T],
\]
\[
u(0) + p(u) = u_0,
\]
\[
u'(0) + q(u) = u_1,
\]
where $u_0, u_1 \in X$, $f^z$ denotes the Riemann-Liouville fractional integral operator, $f : [0,T] \times X \to X$, and $p, q : C(I,X) \to C(I,X)$ are continuous.

Let $A$ be the generator of an $(\alpha,1)$-resolvent family $\{S_{\alpha,1}(t)\}_{t \geq 0}$. Then it is well known that the mild solution of (94) is defined by means of the variation of constant formula
\[
u(t) = S_{\alpha,1}(t)[u_0 - p(u)] + (g_1 * S_{\alpha,1})(t)[u_1 - q(u)] + \int_0^t (g_1 * S_{\alpha,1})(t-s)f(s,u(s))\,ds, \quad t \in I.
\]

We remark that the case $0 < \alpha < 1$ was recently studied in [25, Section 4]. On the other hand, we notice that the case $u' \equiv 0$ and $q \equiv 0$ has been recently studied in [33, Section 4] by assuming the relative compactness of the set $\mathcal{X} = \{S_{\alpha,1}(t-s)f(s,u(s)) : u \in C(I,X), 0 \leq s \leq t\}$. Proposition 16 shows that $S_{\alpha,1}(t)$ is compact for all $t > 0$ and by using the Leray-Schauder alternative theorem (see Theorem 10) it is easy to prove (as in Theorem 21 and [33, Theorem 4.4]) the following result. We omit the details.
Theorem 27. Let $1 < \alpha < 2$. Let $A$ be the generator of an $(\alpha, 1)$-resolvent family $\{S_{\alpha,1}(t)\}_{t \geq 0}$ of type $(M, \omega)$. Suppose that $(\lambda^\alpha - A)^{-1}$ is compact for all $\lambda > \omega^\frac{1}{\alpha}$, and $S_{\alpha,1}(t)$ is continuous in the uniform operator topology for all $t > 0$. Then, under assumptions (H1)--(H3), problem (94) has at least one mild solution.

Now, we consider the Riemann-Liouville fractional Cauchy problem

$$D^\alpha u(t) = Au(t) + j^{2-\alpha} f(t, u(t)), \quad t \in [0, T], \quad (96)$$

$$g_{2-\alpha} * u)(0) + p(u) = u_0,$$

$$g_{2-\alpha} * u)'(0) + q(u) = u_1,$$

where $u_0, u_1 \in X$, $1 < \alpha < 2$, and $A$ is a closed linear operator defined on $X$. Assume that $A$ generates an $(\alpha, 1)$-resolvent family given by $\{S_{\alpha,1}(t)\}_{t \geq 0}$. The mild solution to problem (96) is given by

$$u(t) = S_{\alpha,1}(t)(u_0 - p(u)) + S_{\alpha,1}(t)(u_1 - q(u)) + \int_0^t S_{\alpha,2}(t-s)f(s, u(s))ds, \quad t \in [0, T], \quad (97)$$

which is equivalent (by the uniqueness of the Laplace transform) to

$$u(t) = S_{\alpha,\alpha-1}(t)(u_0 - p(u)) + \int_0^t S_{\alpha,\alpha-1}(t-s)f(s, u(s))ds,$$

for all $t \in [0, T]$.

Proposition 17 shows that $S_{\alpha,\alpha-1}(t)$ is compact for all $t > 0$ and $3/2 < \alpha < 2$ and by using the Leray-Schauder alternative theorem it is easy to prove (as in Theorem 25 and [33, Theorem 4.4] and [25, Theorem 4.1]) the following existence result. We omit the proof.

Theorem 28. Let $3/2 < \alpha < 2$. Let $A$ be the generator of an $(\alpha, \alpha-1)$-resolvent family $\{S_{\alpha,\alpha-1}(t)\}_{t \geq 0}$ of type $(M, \omega)$. Assume that the resolvent $(\lambda^\alpha - A)^{-1}$ is compact for all $\lambda > \omega^{1/\alpha}$ and $S_{\alpha,\alpha-1}(t)$ is continuous in the uniform operator topology for all $t > 0$. Then, under assumptions (H1)--(H3), problem (96) has at least one mild solution.

Example 29. Consider the following problem:

$$D^\alpha u(t, x) = \frac{\partial^2}{\partial x^2} u(t, x) + f(t, u(t, x), \quad t \in [0, 1] \times [0, \pi],$$

$$u(t, 0) = u(t, \pi) = 0, \quad t \in [0, 1], \quad (99)$$

$$u(0, x) + \sum_{k=1}^n a_k u(t, x) = u_0(x), \quad x \in [0, \pi],$$

where $1/2 < \alpha < 1$, $a_k \in \mathbb{R}$, and $n \in \mathbb{N}$. Let $X = L^2([0, \pi])$ and consider the operator $A : D(A) \subset X \rightarrow X$ defined by $D(A) = \{v \in X : v \in H^2([0, \pi]), v(0) = v(\pi)\}$, and for $u \in D(A)$, $Au = \frac{\partial^2 u}{\partial x^2}$.

It is well known that $A$ generates a compact and analytic (and hence norm continuous for all $t > 0$) $C_0$-semigroup $\{T(t)\}_{t \geq 0}$ on $X$ such that $\|T(t)\| \leq 1$ for all $t \geq 0$. Since $A$ generates a $C_0$-semigroup, that is, an $(1, 1)$-resolvent family, we obtain by [29, Corollary 14 and Theorem 3] that $A$ generates the $(\alpha, \alpha)$-resolvent family $\{S_{\alpha,\alpha}(t)\}_{t \geq 0}$ defined by

$$S_{\alpha,\alpha}(t) x = \int_0^\infty e^{-\lambda t} S_{\alpha,\alpha}(\lambda) x d\lambda, \quad t > 0, \ x \in X, \quad (100)$$

where $\varphi_{\alpha,0}$ is the stable Lévy process of order $\alpha$ defined by (22). Since $T(t)$ is norm continuous, it is easy to see that $S_{\alpha,\alpha}(t)$ is norm continuous for all $t > 0$ and the positivity of $\varphi_{\alpha,0}$ (see [29, Theorem 3]) implies that $S_{\alpha,\alpha}(\lambda)$ is of type $(1, 1)$. On the other hand, the compactness of $T(t)$ implies that $(\lambda^\alpha - A)$ is compact.

We notice that problem (99) can be written in the abstract form of (74). Define the functions $f : [0, 1] \times D(A) \rightarrow X$ and $p : D(A) \rightarrow X$ by

$$f(t, u(t, x), \frac{e^{-\lambda t} u(t, x)}{(4 + t)(1 + u(t, x))}, \quad p(u)(x) = \sum_{k=1}^n a_k u(t, x).$$

Assume that $\sum_{k=1}^n |a_k| < 1/4$. We observe also that in this case we have $\mu(t) = \frac{e^{-\lambda t}}{(4 + t)(1 + u(t, x))}, \ T = M = \omega = 1$, and $L p = \|\mu\|_{L\infty} = 1/4$ (see Theorem 23).

It is easy to check assumptions (H1)--(H3) and the hypotheses in Theorem 23 and therefore problem (99) has a mild solution.

Analogously, we can consider the Riemann-Liouville case

$$D^\alpha u(t, x) = \frac{\partial^2}{\partial x^2} u(t, x) + f(t, u(t, x), \quad (t, x) \in [0, 1] \times [0, \pi],$$

$$u(t, 0) = u(t, \pi) = 0, \quad t \in [0, 1], \quad (102)$$

$$u(0, x) + \sum_{k=1}^n a_k u(t, x) = u_0(x), \quad x \in [0, \pi].$$
Under the same assumptions, we have by Theorem 26 that problem (102) has a mild solution.

6.1. Conclusions. In this paper, we obtain conditions implying the compactness of the family \(\{S_{\alpha,\theta}(t)\}_{t \geq 0}\). As a consequence, we obtain several results on the existence of mild solutions to nonlocal fractional Cauchy problems to the Caputo and Riemann-Liouville fractional derivatives.
