We provide an Itô formula for stochastic dynamical equation on general time scales. Based on this Itô's formula we give a closed-form expression for stochastic exponential on general time scales. We then demonstrate Girsanov's change of measure formula in the case of general time scales. Our result is being applied to a Brownian motion on the quantum time scale ($q$-time scale).

1. Introduction

The theory of dynamical equation on time scales ([1]) has attracted many researches recently. In particular, attempts of extension to stochastic dynamical equations and stochastic analysis on general time scales have been made in several previous works ([2–6]). In the work [3] the authors mainly work with a discrete time scale; in [2] the authors introduce an extension of a function and define the stochastic as well as deterministic integrals as the usual integrals for the extended function; in [4] the authors make use of their results on the quadratic variation of a Brownian motion ([7]) on time scales and, based on this, they define the stochastic integral via a generalized version of the Itô isometry; in [6] the authors introduce the so-called $V$-stochastic integral via the backward jump operator and they also derive an Itô formula based on this definition of the stochastic integral. We notice that different previous works adopt different notions of the stochastic integral and there lacks a uniform and coherent theory of a stochastic calculus on general time scales.

The purpose of the present article is to fill in this gap. We will be mainly working under the framework of [2], in that we define our stochastic integral using the definition given in [2]. We then present a general Itô’s formula for stochastic dynamical equations under the framework of [2]. Our Itô formula works for general time scales and thus fills the gap left in [3], which deals with only discrete time scales. By making use of Itô’s formula we obtain a closed-form expression for the stochastic exponential on general time scales. We will then demonstrate a change of measure (Girsanov’s) theorem for stochastic dynamical equation on time scales.

We would like to point out that our change of measure formula is different from the continuous process case in that the density function is not given by the stochastic exponential but rather is found by the fact that the process on the time scale can be extended to a continuous process simply by linear extension.

It is also worth mentioning that our construction is different from [8] in that we are working with the case that the time parameter of the process is running on a time scale, whereas in [8] and related works (e.g., [9–11]) the authors are working with the case that the state space of the process is a time scale.

We note that stochastic calculus on the so-called $q$-Brownian motion has been considered in [12–14]. As an application, we will also work our Itô formula for a Brownian motion on the quantum time scale ($q$-time scale) case at the last section of the paper.

The paper is organized as follows. In Section 2 we discuss some basic set-up for time scales calculus. In Section 3 we will briefly review the results in [2] and define the stochastic integral and stochastic dynamical equation on time scales. In Section 4 we present and prove our Itô formula. In Section 5 we discuss the formula for stochastic exponential. In Section 6 we prove the change of measure (Girsanov’s) formula. Finally in Section 7 we consider an example of Brownian motion on a quantum time scale.
2. Set-Up: Basics of Time Scales Calculus

A time scale \( T \) is an arbitrary nonempty closed subset of the real numbers \( \mathbb{R} \), where we assume that \( T \) has the topology that it inherits from the real numbers \( \mathbb{R} \) with the standard topology.

We define the forward jump operator by
\[
\sigma (t) = \inf \{ s \in T : s > t \}
\]
(1) \( \forall t \in T \) such that this set is nonempty,
and the backward jump operator by
\[
\rho (t) = \sup \{ s \in T : s < t \}
\]
(2) \( \forall t \in T \) such that this set is nonempty.

Let \( t \in T \). If \( \sigma (t) > t \), then \( t \) is called right-scattered. If \( \sigma (t) = t \), then \( t \) is called right-dense. If \( \rho (t) < t \), then \( t \) is called left-scattered. If \( \rho (t) = t \), then \( t \) is called left-dense. Moreover, \( \sigma (t) \) and \( \rho (t) \) are derived from \( T \) as follows: if \( T \) has a left-scattered maximum, then \( \sigma (t) \) is the set \( T \) without that left-scattered maximum; otherwise, \( \sigma (T) = \emptyset \). If \( T \) has a right-scattered minimum, then \( \rho (t) \) is the set \( T \) without that right-scattered minimum; otherwise, \( \rho (t) = \emptyset \). The gramininess function is defined by \( \mu (t) = \sigma (t) - t \) for all \( t \in T \).

Notice that since \( T \) is closed, for any \( t \in T \), the points \( \sigma (t) \) and \( \rho (t) \) are belonging to \( T \).

Given a time scale \( T \) and a function \( f : T \rightarrow \mathbb{R} \), the delta (or Hilger) derivative \( f^\Delta (t) \) of \( f \) at \( t \in T \) is defined as follows ([1, Definition 1.10]).

**Definition 1.** Assume \( f : T \rightarrow \mathbb{R} \) is a function and let \( t \in T^\bullet \). Then we define \( f^\Delta (t) \) to be the number (provided that it exists) with the property that, given any \( \varepsilon > 0 \), there is a neighborhood \( U \) of \( t \) (i.e., \( U = (t - \delta, t + \delta) \cap T \) for some \( \delta > 0 \)) such that
\[
\left| f^\Delta (t) - f(s) - f^\Delta (s) \sigma (t) - s \right| \leq \varepsilon \left| \sigma (t) - s \right| 
\]
\( \forall s \in U \).

The delta derivative is characterized by the following theorem [1, Theorem 1.16].

**Theorem 2.** Assume that \( f : T \rightarrow \mathbb{R} \) is a function and let \( t \in T^\bullet \). Then one has the following:

(i) if \( f \) is differentiable at \( t \), then \( f \) is continuous at \( t \).
(ii) If \( f \) is continuous at \( t \) and \( t \) is right-scattered, then \( f \) is differentiable at \( t \) with
\[
f^\Delta (t) = \frac{f(\sigma (t)) - f(t)}{\sigma (t) - t}.
\]
(4)
(iii) If \( t \) is right-dense, then \( f \) is differentiable at \( t \) if and only if the limit
\[
\lim_{s \to t} \frac{f(t) - f(s)}{t - s}.
\]
(5)

exists as a finite number. In this case
\[
f^\Delta (t) = \lim_{s \to t} \frac{f(t) - f(s)}{t - s}.
\]
(6)

(iv) If \( f \) is differentiable at \( t \), then
\[
f(\sigma (t)) = f(t) + \mu (t) f^\Delta (t).
\]
(7)

3. Stochastic Integrals and Stochastic Differential Equations on Time Scales

We will adopt the definitions introduced in [2] as our definition of a Brownian motion and Itô’s stochastic integral on time scales. In the next section we will derive an Itô formula corresponding to the stochastic integral defined in such a way.

**Definition 3.** A Brownian motion indexed by a time scale \( T \subset \mathbb{R} \) is an adapted stochastic process \( \{ W_t \}_{t \in T} \) on a filtered probability space \( (\Omega, \mathcal{F}, P) \) such that

1. \( P(W_0 = 0) = 1 \);
2. if \( s < t \) and \( s, t \in T \), then the increment \( W_t - W_s \) is independent of \( \mathcal{F}_s \) and is normally distributed with mean 0 and variance \( t - s \);
3. the process \( W_t \) is almost surely continuous on \( T \).

Note that property (3) is proved in the work [5].

For a random function \( f : [0, \infty) \times \Omega \rightarrow \mathbb{R} \) we define the extension \( \tilde{f} : [0, \infty) \times \Omega \rightarrow \mathbb{R} \) by
\[
\tilde{f}(t, \omega) = f \left( \sup_{[0, t]} \mathcal{F} \omega \right)
\]
(8)
for all \( t \in [0, \infty) \).

We shall make use of the definitions given in [2] for the classical Lebesgue and Riemann integral. For any random function \( f : [0, \infty) \times \Omega \rightarrow \mathbb{R} \) and \( T \subset \mathbb{R} \) we define its \( \Delta \)-Riemann (Lebesgue) integral as
\[
\int_0^T f(t, \omega) \Delta t = \int_0^T \tilde{f}(t, \omega) dt,
\]
(9)
where the integral on the right-hand side of the above equation is interpreted as a standard Riemann (Lebesgue) integral. In a similar way, the work [2] defines a stochastic integral for an \( L^2([0, T]) \)-progressively measurable random function \( f(t, \omega) \) as
\[
\int_0^T f(t, \omega) \Delta W_t = \int_0^T \tilde{f}(t, \omega) dW_t,
\]
(10)
where again the right-hand side of the above equation is interpreted as a standard Itô stochastic integral. Note that the way (8) in which we define the extension guarantees that the function \( \tilde{f}(t, \omega) \) is progressively measurable.

In [2] the authors then defined the solution of the \( \Delta \)-stochastic differential equation indicated by the notation
\[
\Delta X_t = b(t, X) \Delta t + \sigma(t, X) \Delta W_t,
\]
(11)
as the process \( \{ X_t \} \in \{0, T \} \) such that
\[
X_{t_2} - X_{t_1} = \int_{t_1}^{t_2} b(t, X_t) \, dt + \int_{t_1}^{t_2} \sigma(t, X_t) \, dW_t,
\]
(12)
with the deterministic and stochastic integrals on the right-hand side of the above equality interpreted as was just mentioned. Under the condition of continuity in the \( t \)-variable and uniform Lipschitz continuity in the \( x \)-variable of the functions \( b(t, x) \) and \( \sigma(t, x) \), together with being no worse than linear growth in \( x \)-variable, existence and pathwise uniqueness of strong solution to (11) are proved in [2].

4. Itô’s Formula for Stochastic Integrals on Time Scales

We will make use of the following fact that is simple to prove.

**Proposition 4.** The set of all left-scattered or right-scattered points of \( \mathbb{T} \) is at most countable.

**Proof.** If \( x \in \mathbb{T} \) is a right-scattered point, then \( I_x = (x, \sigma(x)) \) is an open interval such that \( I_x \cap \mathbb{T} = \emptyset \). Similarly, if \( x \in \mathbb{T} \) is a left-scattered point, then \( I_x = (\rho(x), x) \) is an open interval such that \( I_x \cap \mathbb{T} = \emptyset \). Suppose \( x < y \) and \( x, y \in \mathbb{T} \). We then distinguish four different cases.

**Case 1** (both \( x \) and \( y \) are right-scattered). We argue that in this case we have \( I_{x} \cap I_{y} = \emptyset \). Suppose this is not the case, then we must have \( \sigma(x) > y \). But we see that \( \sigma(x) = \inf \{ s : x \leq s \in \mathbb{T} \} \) and \( y \in \mathbb{T} \). We then arrive at a contradiction.

**Case 2** (both \( x \) and \( y \) are left-scattered). This case is similar to Case 1 and we conclude that \( I_{x} \cap I_{y} = \emptyset \).

**Case 3** (\( x \) is left-scattered; \( y \) is right-scattered). In this case we see that \( I_{x} = (\rho(x), x) \) and \( I_{y} = (y, \sigma(y)) \), as well as \( y < x \). This implies that \( I_{x} \cap I_{y} = \emptyset \).

**Case 4** (\( x \) is right-scattered; \( y \) is left-scattered). In this case \( I_{x} = (x, \sigma(x)) \) and \( I_{y} = (\rho(y), y) \). If \( \sigma(x) \leq \rho(y) \), then \( I_{x} \cap I_{y} = \emptyset \). If \( \sigma(x) > \rho(y) \), then we see that \( x, y \) is \( I_{x} \cup I_{y} \) so that \( (x, y) \cap \mathbb{T} = \emptyset \). That implies further that \( \sigma(x) = y \) and \( \rho(y) = x \); that is, \( I_{x} \cap I_{y} = \emptyset \).

Thus we see that for all points \( x \in \mathbb{T} \) being left- or right-scattered, the set of all open intervals of the form \( I_{x} \) is disjoint subsets of \( \mathbb{T} \). Henceforth there are at most countably many such intervals. Each such interval corresponds to one or two endpoints in \( \mathbb{T} \) that are either left- or right-scattered. Thus the total number of left- or right-scattered points in \( \mathbb{T} \) is at most countably many.

Let \( C \) be the (at most) countable set of all left-scattered or right-scattered points of \( \mathbb{T} \). As we have already seen in the proof of the previous proposition, the set \( C \) corresponds to at most countably many open intervals \( \mathcal{I} = \{ I_1, I_2, \ldots \} \) such that (1) for any \( k \neq l \), \( I_k \cap I_l = \emptyset \); (2) either the left-endpoint or right-endpoint or both endpoints of any of the \( I_k \)'s are in \( \mathbb{T} \) and are left- or right-scattered; (3) \( I_k \cap \mathbb{T} = \emptyset \) for any \( k = 1, 2, \ldots \); (4) any point in \( C \) is a left- or right-endpoint of one of the \( I_k \)'s.

We will denote \( I_k = (s_{I_k}^-, s_{I_k}^+) \). Since, for any \( x \in \mathbb{T} \), the points \( \sigma(x) \) and \( \rho(x) \) are in \( \mathbb{T} \), we further infer that, for any such interval \( I_k \), we have the fact that \( s_{I_k}^- \) and \( s_{I_k}^+ \) are in \( \mathbb{T} \), so that \( s_{I_k}^- \) is right-scattered and \( s_{I_k}^+ \) is left-scattered.

We then establish the following Itô formula.

For any two points \( t_1, t_2 \in \mathbb{T} \), \( t_1 \leq t_2 \), and any open interval \( I_k \in \mathcal{I} \), such that \( I_k \cap [t_1, t_2] \neq \emptyset \), we have \( I_k \subset (t_1, t_2) \). This is because if it is not the case, then \( t_1, t_2 \) will belong to \( I_k \), contradictory to the fact that \( I_k \cap \mathbb{T} = \emptyset \). We conclude that
\[
\{ I_k \in \mathcal{I} : I_k \cap (t_1, t_2) \neq \emptyset \} = \{ I_k \in \mathcal{I} : I_k \subset (t_1, t_2) \}.
\]

Let us consider a function \( f(t, x) : \mathbb{T} \times \mathbb{R} \to \mathbb{R} \). Let \( f^2(t, x), f^2(t, x) \) be the first- and second-order delta (Hilger) derivatives of \( f \) with respect to time variable at \( (t, x) \) and let \( \Delta \nu(\delta f/\delta x)(t, x) \) and \( \Delta^2 \nu(\delta^2 f/\delta x^2)(t, x) \) be the first- and second-order partial derivatives of \( f \) with respect to space variable \( x \) at \((t, x)\).

**Theorem 5** (Itô’s formula). Let any function \( f : \mathbb{T} \times \mathbb{R} \to \mathbb{R} \) be such that \( f^2(t, x), f^2(t, x) \), \( \Delta^2 \nu(\delta^2 f/\delta x^2)(t, x) \), and \( \Delta \nu(\delta f/\delta x)(t, x) \) are continuous on \( \mathbb{T} \times \mathbb{R} \). Set any \( t_1 \leq t_2, t_1, t_2 \in [0, \infty) \cap \mathbb{T} \), then we have
\[
\begin{align*}
&f(t_2, \tilde{X}_{t_2}) - f(t_1, \tilde{X}_{t_1}) = \int_{t_1}^{t_2} f^2(s, W_s) \, ds + \int_{t_1}^{t_2} \Delta^2(\delta^2 f/\delta x^2)(s, W_s) \, ds \\
&\quad + \int_{t_1}^{t_2} \Delta \nu(\delta f/\delta x)(s, W_s) \, ds + \int_{t_1}^{t_2} \Delta^2 \nu(\delta^2 f/\delta x^2)(s, W_s) \, ds \\
&\quad + \sum_{I_k \in \mathcal{I}} \left[ f(s_{I_k}^-, W_{s_{I_k}^-}^+) - f(s_{I_k}^+, W_{s_{I_k}^+}^-) \right] \left( W_{s_{I_k}^+}^- - W_{s_{I_k}^-}^+ \right) \\
&\quad - \frac{\Delta^2(\delta^2 f/\delta x^2)}{2 \Delta x^2}(s_{I_k}^-) \left( W_{s_{I_k}^+}^- - W_{s_{I_k}^-}^+ \right) \left( s_{I_k}^+ - s_{I_k}^- \right)
\end{align*}
\]
(14)

**Proof.** We will make use of the following classical version (Peano form) of Taylor’s theorem: for any function \( f : \mathbb{T} \times \mathbb{R} \to \mathbb{R} \) such that \( \Delta \nu(\delta f/\delta x)(t, x) \) and \( \Delta^2 \nu(\delta^2 f/\delta x^2)(t, x) \) are continuous on \( \mathbb{T} \times \mathbb{R} \), and any \( s \in \mathbb{T} \) and \( x_1, x_2 \in \mathbb{R} \), we have
\[
\begin{align*}
f(s, x_2) - f(s, x_1) &= \frac{\Delta f}{\Delta x}(s, x_1)(x_2 - x_1) \\
&\quad + \frac{\Delta^2 f}{2 \Delta x^2}(s, x_1)(x_2 - x_1)^2 + R_C(s, x_1, x_2),
\end{align*}
\]
(15)
where
\[ R^C_f(s; x_1, x_2) = r \left( \{x_2 - x_1\} \right) (x_2 - x_1)^2, \tag{16} \]
and \( r : \mathbb{R}_+ \to \mathbb{R}_+ \) is an increasing function with \( \lim_{u \to 0^+} r(u) = 0 \).

We will also make use of the time scale Taylor formula (see [1, Theorem 1.113] as well as [15]) applied to \( f(t, x) \) up to first order in \( t \): for any \( s_2 > s_1 \) and \( s_1, s_2, s \in \mathbb{T} \), we have
\[
\begin{align*}
f(s_2, x) - f(s_1, x) & = f^\Delta(s_1, x) (s_2 - s_1) \\
\quad & + R^T_f(x; s_1, s_2),
\end{align*}
\tag{17}
\]
where
\[
\begin{align*}
\left| R^T_f(x; s_1, s_2) \right| & = \left| \int_{s_1}^{s_2} \left( s_2 - \sigma(s) \right) f^\Delta(s) \Delta s \right| \\
& \leq r \left( \left| s_2 - s_1 \right| \right) \left| s_2 - s_1 \right|
\end{align*}
\tag{18}
\]
with \( r(\bullet) \) as before.

Combining (15) and (17) we see that we have
\[
\begin{align*}
f(s_2, x_2) - f(s_1, x_1) & = \left[ f(s_2, x_2) - f(s_1, x_2) \right] \\
\quad & + \left[ f(s_1, x_2) - f(s_1, x_1) \right] \\
\quad & + \frac{\partial f}{\partial x}(s_1, x_1) (x_2 - x_1) + 1 \frac{\partial^2 f}{2 \partial x^2}(s_1, x_1) (x_2 - x_1)^2 \\
\quad & + R^T_f(x_2; s_1, s_2) + R^C_f(s_1; x_1, x_2) \\
\quad & = \left[ f^\Delta(s_1, x_1) \\
\quad & + \frac{\partial f}{\partial x}(s_1, x_1) (x_2 - x_1) \\
\quad & + 1 \frac{\partial^2 f}{2 \partial x^2}(s_1, x_1) (x_2 - x_1)^2 + R^C_f(s_1; x_1, x_2) \right] (s_2 - s_1) \\
\quad & - s_1 + \frac{\partial f}{\partial x}(s_1, x_1) (x_2 - x_1) + 1 \frac{\partial^2 f}{2 \partial x^2}(s_1, x_1) (x_2 - x_1)^2 \\
\quad & + R^T_f(x_2; s_1, s_2) + R^C_f(s_1; x_1, x_2) \\
\quad & = f^\Delta(s_1, x_1) (x_2 - s_1) + \frac{\partial f}{\partial x}(s_1, x_1) (x_2 - x_1) + \frac{1}{2} \\
\quad & \cdot \frac{\partial^2 f}{\partial x^2}(s_1, x_1) (x_2 - x_1)^2 + R(s_1, s_2; x_1, x_2),
\end{align*}
\tag{19}
\]
with
\[
\left| R(s_1, s_2; x_1, x_2) \right| \leq r \left( \left| x_2 - s_1 \right| \right) \left| x_2 - s_1 \right| \\
\quad + r \left( \left| x_2 - x_1 \right| \right) \left( x_2 - x_1 \right)^2
\tag{20}
\]
for another function \( r : \mathbb{R}_+ \to \mathbb{R}_+ \) increasing with \( \lim_{u \to 0^+} r(u) = 0 \).

Consider a partition \( n^{(n)} : t_1 = s_0 < s_1 < \ldots < s_n = t_2 \), such that (1) each \( s_j \in \mathbb{T} \); (2) \( \max \{ \rho(s_j - s_{j-1}) \} \leq 1/2^n \) for \( i = 1, 2, \ldots, n \). Notice that by definition \( \rho(s_j) = \sup \{ s < s_j : s \in \mathbb{T} \} \), so that we can always find \( s_{j-1} \in \mathbb{T} \) so that \( \rho(s_j) - s_{j-1} \) is sufficiently small.

Let the sets \( C \) and \( \mathcal{F} \) be defined as before. Let us fix a partition \( n^{(n)} \), and consider a classification of its corresponding intervals \( (s_{i-1}, s_i) \), \( i = 1, 2, \ldots, n \). We will classify all intervals \( (s_{i-1}, s_j) \) such that for all \( k \in \mathcal{F} \) we have \( I_k \cap (s_{i-1}, s_j) = 0 \) as class (a); and we classify all intervals \( (s_{j-1}, s_j) \) such that there exist \( I_k \in \mathcal{F} \) with \( (s_{i-1}, s_j) \cap I_k 
eq 0 \) as class (b). For an interval \( (s_{j-1}, s_j) \) in class (a), since for all \( I_k \in \mathcal{F} \) we have \( I_k \cap (s_{j-1}, s_j) = 0 \), we see that \( \rho(s_j) = s_j \), because otherwise \( \rho(s_j) \) will be one of the \( I_k \)'s. Thus in this case we have \( s_j - s_{j-1} < 1/2^n \). For an interval \( (s_{j-1}, s_j) \) in class (b), since both \( s_{j-1} \) and \( s_j \) are in \( \mathbb{T} \), we see that we have in fact \( I_k \subseteq (s_{j-1}, s_j) \). In this case either \( I_k = (s_{j-1}, s_j) \), or \( I_k \neq (s_{j-1}, s_j) \).

If the latter happens, then \( \rho(s_j), s_j \in \mathcal{F} \) is one of the \( I_k \)'s and \( \rho(s_j) - s_{j-1} < 1/2^n \). We also see from the above analysis that all \( I_k \)'s are contained in intervals \( (s_{j-1}, s_j) \) that belong to class (b). On the other hand, either each interval \( (s_{j-1}, s_j) \) is entirely one of the \( I_k \)'s, or it contains an interval \( (\rho(s_j), s_j) \) that is one of the \( I_k \)'s. For the latter case, that is, when \( s_{j-1} < \rho(s_j) < s_j \), the set of intervals of the form \( (s_{j-1}, \rho(s_j)) \) are disjoint open intervals such that
\[
\sum_{s_{j-1} < \rho(s_j) < s_j} (\rho(s_j) - s_{j-1}) < \frac{n}{2^n}. \tag{21}
\]

Now we have
\[
\begin{align*}
f(t_2, W_{s_2}) - f(t_1, W_{s_1}) & = \sum_{j=1}^{n} \left[ f(s_j, W_{s_j}) - f(s_{j-1}, W_{s_{j-1}}) \right] \\
= \sum_{(a)} \left[ f(s_j, W_{s_j}) - f(s_{j-1}, W_{s_{j-1}}) \right] \\
& + \sum_{(b)} \left[ f(s_j, W_{s_j}) - f(s_{j-1}, W_{s_{j-1}}) \right] = (I) + (II).
\end{align*}
\tag{22}
\]

We apply (19) term by term in part (I) of (22), and we get
\[
(I) = \sum_{(a)} \left[ f(s_j, W_{s_j}) - f(s_{j-1}, W_{s_{j-1}}) \right] \\
= \sum_{(a)} \left[ f^\Delta(s_{j-1}, W_{s_{j-1}}) (s_j - s_{j-1}) \\
+ \frac{\partial f}{\partial x}(s_{j-1}, W_{s_{j-1}}) (W_{s_j} - W_{s_{j-1}}) \\
+ 1 \frac{\partial^2 f}{2 \partial x^2}(s_{j-1}, W_{s_{j-1}}) (W_{s_j} - W_{s_{j-1}})^2 \right].
\]
We have the following four convergence results.

Convergence Result 1.1. By Lemma 6 ((35) and (36)) established below we have

\[
P \left( (III)_1 \rightarrow \int_{t_1}^{t_2} f^A_s(s, W_s) \, ds \right) + \int_{t_1}^{t_2} \frac{\partial f}{\partial x}(s, W_s) \, ds \; \text{as} \; n \rightarrow \infty = 1. \tag{24}
\]

Convergence Result 1.2. By Lemma 7, (43), and Lemma 6, (35), established below we have

\[
P \left( (III)_2 \rightarrow \int_{t_1}^{t_2} \frac{\partial^2 f}{\partial x^2}(s, W_s) \, ds \; \text{as} \; n \rightarrow \infty \right) = 1. \tag{25}
\]

Convergence Result 2. We have, with probability one, that

\[
(V) = \sum_{(a)} R(s_{i-1}, s_i; W_{s_{i-1}}, W_s) \rightarrow 0 \quad \text{as} \; n \rightarrow \infty. \tag{26}
\]

In fact, by the Kolmogorov–Čentsov theorem proved in Theorem 3.1 of [5] we know that for almost all trajectories of \( W_s \) on \( T \), for each fixed trajectory \( W(\omega) \), there exists an \( n_0 = n_0(\omega) \) such that for all \( n \geq n_0 \), there exists an \( \delta > 0 \) with a classification of its intervals \( (s_{i-1}, s_i) \) into classes (a) and (b) as above, \( \sup_{|\omega|}|W_{s_i} - W_{s_{i-1}}| \leq \delta / 2^{n_0/5} \) for some fixed \( \delta > 0 \) and \( \gamma > 0 \). From here we can estimate

\[
E \sum_{(a)} R(s_{i-1}, s_i; W_{s_{i-1}}, W_s) \leq E \sum_{(a)} \left[ r(s_{i-1}, s_i) (s_i - s_{i-1}) + \rho \left( |W_{s_i} - W_{s_{i-1}}| \right) (W_{s_i} - W_{s_{i-1}}) \right] \leq r \left( \frac{1}{2^n} \right) (t_2 - t_1) \tag{27}
\]

that is,

\[
P \left( \lim_{n \rightarrow \infty} \sum_{(a)} R(s_{i-1}, s_i; W_{s_{i-1}}, W_s) = 0 \right) = 1. \tag{28}
\]

Convergence Result 3. Let

\[
(II) + (IV) = A_n = A_n(\omega) = \sum_{(b)} f(s, W_s) - f^A(s_{i-1}, W_{s_{i-1}}) (s_i - s_{i-1}) \tag{29}
\]

\[
- \frac{\partial f}{\partial x}(s_{i-1}, W_{s_{i-1}}) (W_{s_i} - W_{s_{i-1}}) \quad \text{and} \quad \frac{1}{2} \frac{\partial^2 f}{\partial x^2}(s_{i-1}, W_{s_{i-1}}) (s_i - s_{i-1})
\]

\[
B_n = B_n(\omega) = \sum_{\{b \}} \frac{\partial f}{\partial x}(s_{i-1}, W_{s_{i-1}}) (W_{s_i} - W_{s_{i-1}}) \quad \text{and} \quad \frac{1}{2} \frac{\partial^2 f}{\partial x^2}(s_{i-1}, W_{s_{i-1}}) (s_i - s_{i-1})
\]

We claim that we have

\[
P \left( |A_n(\omega) - B_n(\omega)| \rightarrow 0 \; \text{as} \; n \rightarrow \infty \right) = 1. \tag{30}
\]
In fact, from the analysis that leads to estimate (17) we see that we can write $A_n - B_n$ as

\[
A_n - B_n = \sum_{(s_i, s_{i+1}) \in (b, a), s_i < s_{i+1}} \left[ f(s_i, W_{s_i}) - f(s_{i-1}, W_{s_{i-1}}) - f^\Delta(s_{i-1}, W_{s_{i-1}})(s_i - s_{i-1}) \right. \\
- \frac{\partial f}{\partial x}(s_{i-1}, W_{s_{i-1}})(W_{s_{i-1}} - W_{s_{i-1}}) \left. - \frac{1}{2} \frac{\partial^2 f}{\partial x^2}(s_{i-1}, W_{s_{i-1}})(s_i - s_{i-1}) \right] \\
- \sum_{(s_i, s_{i+1}) \in (b, a), s_i < s_{i+1}} \left[ f(s_i, W_{s_i}) - f^\Delta(s_i, W_{s_i}) - f^\Delta(s_i, W_{s_i})(s_i - \rho(s_i)) \right. \\
- \frac{\partial f}{\partial x}(s_i, W_{s_i})(W_{s_i} - W_{s_i}) \left. - \frac{1}{2} \frac{\partial^2 f}{\partial x^2}(s_i, W_{s_i})(s_i - \rho(s_i)) \right] \\
- \sum_{I_k \in J_1} \sum_{(s_i, s_{i+1}) \in (b)} \left[ f(s_{i+1}, W_{s_{i+1}}) - f^\Delta(s_{i+1}, W_{s_{i+1}})(s_{i+1} - s_i) \right. \\
- \frac{\partial f}{\partial x}(s_{i+1}, W_{s_{i+1}})(W_{s_{i+1}} - W_{s_{i+1}}) \left. - \frac{1}{2} \frac{\partial^2 f}{\partial x^2}(s_{i+1}, W_{s_{i+1}})(s_{i+1} - \rho(s_i)) \right] \\
- \frac{\partial f}{\partial x}(s_i, W_{s_i})(W_{s_i} - W_{s_i}) \left. - \frac{1}{2} \frac{\partial^2 f}{\partial x^2}(s_i, W_{s_i})(s_i - \rho(s_i)) \right] = (VI)_1 + (VI)_2 \\
+ (VI)_3 + (VI)_4 - (VII).
\]

Here

\[
(VI)_1 = \sum_{(s_i, s_{i+1}) \in (b, a), s_i < s_{i+1}} \left[ f(\rho(s_i), W_{\rho(s_i)}) - f(s_{i-1}, W_{s_{i-1}}) \right] \\
(VI)_2 = \sum_{(s_i, s_{i+1}) \in (b, a), s_i < s_{i+1}} \left[ f^\Delta(\rho(s_i), W_{\rho(s_i)})(s_i - \rho(s_i)) - f^\Delta(s_{i-1}, W_{s_{i-1}})(s_i - s_{i-1}) \right] \\
- \sum_{(s_i, s_{i+1}) \in (b, a), s_i < s_{i+1}} \left[ (f^\Delta(\rho(s_i), W_{\rho(s_i)}) - f^\Delta(s_{i-1}, W_{s_{i-1}}) - f^\Delta(s_{i-1}, W_{s_{i-1}}) - f^\Delta(\rho(s_i), W_{\rho(s_i)}) \right. \\
\cdot (\rho(s_i) - s_{i-1}) \right], \\
(VI)_3 = \sum_{(s_i, s_{i+1}) \in (b, a), s_i < s_{i+1}} \left[ f^\Delta(\rho(s_i), W_{\rho(s_i)})(W_{s_i} - W_{s_{i-1}}) - W_{\rho(s_i)}(W_{s_i} - W_{s_{i-1}}) \right] \\
- \sum_{(s_i, s_{i+1}) \in (b, a), s_i < s_{i+1}} \left[ (f^\Delta(\rho(s_i), W_{\rho(s_i)}) - f^\Delta(s_{i-1}, W_{s_{i-1}}) - f^\Delta(s_{i-1}, W_{s_{i-1}}) \right. \\
- f^\Delta(s_{i-1}, W_{s_{i-1}}))(W_{s_i} - W_{s_{i-1}}) - f^\Delta(\rho(s_i), W_{\rho(s_i)}) - f^\Delta(s_{i-1}, W_{s_{i-1}})) \right] \\
+ (VII)_1 = \sum_{I_k \in J_1} \sum_{(s_i, s_{i+1}) \in (b)} \left[ f(s_{i+1}^+, W_{s_{i+1}^+}) - f(s_{i+1}^+, W_{s_{i+1}^+})(s_{i+1}^+ - s_i^+) \right. \\
- \frac{\partial f}{\partial x}(s_{i+1}^+, W_{s_{i+1}^+})(W_{s_{i+1}^+} - W_{s_{i+1}^+}) - \frac{1}{2} \frac{\partial^2 f}{\partial x^2}(s_{i+1}^+, W_{s_{i+1}^+}) \left. (s_{i+1}^+ - \rho(s_i)) \right] \\
+ (VII)_2 = \sum_{I_k \in J_1} \sum_{(s_i, s_{i+1}) \in (b)} \left[ f(s_{i+1}^+, W_{s_{i+1}^+}) - f(s_{i+1}^+, W_{s_{i+1}^+})(s_{i+1}^+ - s_i^+) \right. \\
- \frac{\partial f}{\partial x}(s_{i+1}^+, W_{s_{i+1}^+})(W_{s_{i+1}^+} - W_{s_{i+1}^+}) - \frac{1}{2} \frac{\partial^2 f}{\partial x^2}(s_{i+1}^+, W_{s_{i+1}^+}) \left. (s_{i+1}^+ - \rho(s_i)) \right] \right]. \\
\]

From (21), the Kolmogorov–Čentsov theorem proved in Theorem 3.1 of [5], as well as the assumptions about function $f$, we see that

\[
P(||(VI)_1|| + ||(VI)_2|| + ||(VI)_3|| + ||(VI)_4|| + ||(VII)||) \\
\rightarrow 0 \text{ as } n \rightarrow \infty = 1. \\
\]
Abstract and Applied Analysis

Lemma 6 (convergence of Δ-deterministic and stochastic integrals). Given a time scale $\mathbb{T}$ and $t_1,t_2 \in \mathbb{T}$, $t_1 < t_2$; a probability space $(\Omega, \mathcal{F}, P)$; a Brownian motion $\{W_t\}_{t \in \mathbb{T}}$ on the time scale $\mathbb{T}$; for any progressively measurable random function $f$ that is continuous on $[t_1,t_2] \cap \mathbb{T}$, viewed as a $L^2([t_1,t_2]_\mathbb{T})$-progressively measurable random function $f(t, \omega)$ on $\mathbb{T}$, and the families of partitions $\pi^{(n)}$ : $t_1 = s_0 < s_1 < \ldots < s_n = t_2$, $s_0, s_1, \ldots, s_n \in \mathbb{R}$, $\max_{i=1,2,\ldots,n}(\rho(s_i) - s_{i-1}) < 1/2^n$, one has

$\mathbb{P}\left( \lim_{n \to \infty} \sum_{i=1}^{n} f(s_{i-1}, \omega) (s_i - s_{i-1}) = \int_{t_1}^{t_2} f(s, \omega) \Delta s \right) = 1,$

$\mathbb{P}\left( \lim_{n \to \infty} \sum_{i=1}^{n} f(s_{i-1}, \omega) (W_{s_i} - W_{s_{i-1}}) = \int_{t_1}^{t_2} f(s, \omega) \Delta W_s \right) = 1.$

Proof. As we have seen in the proof of Itô's formula, for a given partition $\pi^{(n)}$ : $t_1 = s_0 < s_1 < \ldots < s_n = t_2$, such that $s_i \in \mathbb{R}$ for $i = 0, 1, \ldots, n$, and $\max_{i=1,2,\ldots,n}(\rho(s_i) - s_{i-1}) < 1/2^n$, we can classify all intervals of the form $(s_{i-1}, s_i)$ into two classes (a) and (b); class (a) is those open intervals $(s_{i-1}, s_i)$ such that it does not contain any open intervals $I_k \in \mathcal{I}$; class (b) is those open intervals $(s_{i-1}, s_i)$ such that it contains at least one open interval $I_k \in \mathcal{I}$, the latter of which has endpoints that are left- or right-scattered.

Let us form a family of partitions $\sigma^{(n)}$ : $t_1 = r_0 < r_1 < \cdots < r_m = t_2$, so that the partition $\sigma^{(n)}$ is the partition $\pi^{(n)}$ together with all points in $\mathbb{R}$ that are of the form $r_j = \rho(s_j)$ for some $s_j$ in the partition $\pi^{(n)}$. Note that under this construction we have $r_0, r_1, \ldots, r_m \in \mathbb{R}$. In fact, for any interval $(s_{i-1}, s_i)$ in (a), there is an identical interval $(r_{j-1}, r_j)$ in the partition $\sigma^{(n)}$ corresponding to it; for any interval $(s_{i-1}, s_i)$ in (b), there are two intervals $(r_{j-2}, r_{j-1})$ and $(r_{j-1}, r_j)$ corresponding to it, so that $r_{j-1} = \rho(s_i)$. And by (21) we know that

$\sum_{(s_{i-1},s_{i}) \in (b), (r_{j-1}, r_j)} (r_{j-1} - r_{j-2}) < \frac{n}{2^n}.$

Note that the number $m$ depends on $n$ and the partition $\pi^{(n)} : m = m(n, \pi^{(n)})$. In particular $m \to \infty$ as $n \to \infty$. For simplicity we will suppress this dependence later in our proof.

Let us recall the definition of deterministic and stochastic $\Delta$-integrals as defined in Section 2. Let $\tilde{f}$ be the extension of $f$ that we have in (8): for any $t \in \mathbb{T}$,

$\tilde{f}(t, \omega) = f(\sup [0,t]_\mathbb{T}, \omega).$
For any open interval \((s_{j-1}, s_j)\) in class (b), there are two corresponding intervals \((r_{j-2}, r_{j-1})\) and \((r_{j-1}, r_j)\) such that \(r_{j-2} = s_{j-1}, r_{j-1} = \rho(s_j)\), and \(r_j = s_j\). In this case

\[
\begin{align*}
&f(s_{j-1}, \omega) (s_j - s_{j-1}) - f(r_{j-1}, \omega) (r_j - r_{j-1}) \\
&\quad - f(r_{j-2}, \omega) (r_{j-1} - r_{j-2}) = f(s_{j-1}, \omega) (s_j - s_{j-1}) \\
&\quad - f(\rho(s_j), \omega) (s_j - \rho(s_j)) \\
&\quad - f(s_{j-1}, \omega) (\rho(s_j) - s_{j-1}) \\
&\quad = (f(s_{j-1}, \omega) - f(\rho(s_j), \omega)) (s_j - \rho(s_j)),
\end{align*}
\]

\[
f(s_{j-1}, \omega) (W_{s_j} - W_{s_{j-1}}) - f(r_{j-1}, \omega) (W_{r_j} - W_{r_{j-1}}) \\
- f(r_{j-2}, \omega) (W_{r_{j-1}} - W_{r_{j-2}}) = f(s_{j-1}, \omega) (W_{s_j} - W_{s_{j-1}}) \\
- f(\rho(s_j), \omega) (W_{s_j} - \rho(s_j)) \\
- f(s_{j-1}, \omega) (\rho(s_j) - W_{s_{j-1}}) \\
= (f(s_{j-1}, \omega) - f(\rho(s_j), \omega)) (W_{s_j} - \rho(s_j)).
\]

From the above calculations and the fact that we have (21) and that \(f\) is continuous on \([t_1, t_2]\) in \(\mathbb{T}\), together with the fact that \(s_{j-1}, \rho(s_j) \in \mathbb{T}, 0 \leq \rho(s_j) - s_{j-1} \leq 1/2^n\), we see the claim as follows.

\[\square\]

**Lemma 7** (convergence of quadratic variation of Brownian motion on time scale). *Given a time scale \(\mathbb{T}\) and \(t_1, t_2 \in \mathbb{T}, t_1 < t_2\); a probability space \((\Omega, \mathcal{F}, \mathbb{P})\); a Brownian motion \(\{W_t\}_{t \in \mathbb{T}}\) on the time scale \(\mathbb{T}\), let any \(L^2([t_1, t_2])\)-progressively measurable random function \(f(t, \omega)\) on \(\mathbb{T}\) be defined such that \(\mathbb{E}f^2(t, \omega)\) is uniformly bounded on \([t_1, t_2]\). Consider the families of partitions \(\pi^{(n)} : t_1 = s_0 < s_1 < \cdots < s_n = t_2\), where \(s_0, s_1, \ldots, s_n \in \mathbb{T}, \max_{1 \leq j \leq n} (s_j - s_{j-1}) < 1/2^n\). One classifies all the intervals \((s_{j-1}, s_j), j = 1, 2, \ldots, n\) into two classes (a) and (b) as before. Then one has

\[
P \left( \lim_{n \to \infty} \left[ \sum_{(a)} f(s_{j-1}, \omega) (W_{s_j} - W_{s_{j-1}}) \right]^2 - \sum_{(a)} f(s_{j-1}, \omega) (s_j - s_{j-1}) \right) = 0 = 1.
\]

**Proof.** We notice that for all intervals \((s_{j-1}, s_j) \in (a)\) we have \(\rho(s_j) = s_{j-1}\) and thus \(s_j - s_{j-1} < 1/2^n\). Let us denote that

\[
V_n = \left[ \sum_{(a)} f(s_{j-1}, \omega) (W_{s_j} - W_{s_{j-1}}) \right]^2 - \sum_{(a)} f(s_{j-1}, \omega) (s_j - s_{j-1})
\]

Since \(f(t, \omega)\) is progressively measurable, we see that \(f(s_{j-1}, \omega)\) is independent of \(W_{s_j} - W_{s_{j-1}}\). Thus

\[
\mathbb{E}V_n = \mathbb{E} \left[ \sum_{(a)} f(s_{j-1}, \omega) (W_{s_j} - W_{s_{j-1}}) \right]^2 - \sum_{(a)} f(s_{j-1}, \omega) (s_j - s_{j-1})
\]

\[
= \sum_{(a)} \mathbb{E}f(s_{j-1}, \omega) (s_j - s_{j-1}) = 0.
\]

Furthermore

\[
\mathbb{E} = \mathbb{E} \left[ \sum_{(a)} f(s_{j-1}, \omega) (W_{s_j} - W_{s_{j-1}}) \right]^2 - \sum_{(a)} f(s_{j-1}, \omega) (s_j - s_{j-1})
\]

\[
= \sum_{(a)} \mathbb{E}f(s_{j-1}, \omega) (s_j - s_{j-1}) = 0.
\]

\[
\mathbb{E} = \mathbb{E} \left[ \sum_{(a)} f(s_{j-1}, \omega) (W_{s_j} - W_{s_{j-1}}) \right]^2 - \sum_{(a)} f(s_{j-1}, \omega) (s_j - s_{j-1})
\]

\[
= \sum_{(a)} \mathbb{E}f(s_{j-1}, \omega) (s_j - s_{j-1}) = 0.
\]

\[
\mathbb{E} = \mathbb{E} \left[ \sum_{(a)} f(s_{j-1}, \omega) (W_{s_j} - W_{s_{j-1}}) \right]^2 - \sum_{(a)} f(s_{j-1}, \omega) (s_j - s_{j-1})
\]

\[
= \sum_{(a)} \mathbb{E}f(s_{j-1}, \omega) (s_j - s_{j-1}) = 0.
\]

If \(i < j\), then \(f(s_{j-1}, \omega) f(s_{j-1}, \omega) ((W_{s_j} - W_{s_{j-1}})^2 - (s_j - s_{j-1}))\) is independent of \([(W_{s_j} - W_{s_{j-1}})^2 - (s_j - s_{j-1})]\), so we have \(\mathbb{E}f(s_{j-1}, \omega) f(s_{j-1}, \omega) ((W_{s_j} - W_{s_{j-1}})^2 - (s_j - s_{j-1})) = 0\). Similarly, for \(i > j\) we also have \(\mathbb{E}f(s_{j-1}, \omega) f(s_{j-1}, \omega) ((W_{s_j} - W_{s_{j-1}})^2 - (s_j - s_{j-1})) = 0\). This implies that

\[
\mathbb{E} = \mathbb{E} \left[ \sum_{(a)} f(s_{j-1}, \omega) (W_{s_j} - W_{s_{j-1}}) \right]^2 - \sum_{(a)} f(s_{j-1}, \omega) (s_j - s_{j-1})
\]

\[
= \sum_{(a)} \mathbb{E}f(s_{j-1}, \omega) (s_j - s_{j-1}) = 0.
\]

\[
\mathbb{E} = \mathbb{E} \left[ \sum_{(a)} f(s_{j-1}, \omega) (W_{s_j} - W_{s_{j-1}}) \right]^2 - \sum_{(a)} f(s_{j-1}, \omega) (s_j - s_{j-1})
\]

\[
= \sum_{(a)} \mathbb{E}f(s_{j-1}, \omega) (s_j - s_{j-1}) = 0.
\]

\[
\mathbb{E} = \mathbb{E} \left[ \sum_{(a)} f(s_{j-1}, \omega) (W_{s_j} - W_{s_{j-1}}) \right]^2 - \sum_{(a)} f(s_{j-1}, \omega) (s_j - s_{j-1})
\]

\[
= \sum_{(a)} \mathbb{E}f(s_{j-1}, \omega) (s_j - s_{j-1}) = 0.
\]

\[
\mathbb{E} = \mathbb{E} \left[ \sum_{(a)} f(s_{j-1}, \omega) (W_{s_j} - W_{s_{j-1}}) \right]^2 - \sum_{(a)} f(s_{j-1}, \omega) (s_j - s_{j-1})
\]

\[
= \sum_{(a)} \mathbb{E}f(s_{j-1}, \omega) (s_j - s_{j-1}) = 0.
\]
The following definition of a stochastic exponential was also introduced in [3].

Definition 10 (stochastic exponential). Let \( t_0 \in \mathbb{T} \) and \( A \in \mathcal{R}_W \); then the unique solution of the \( \Delta \)-stochastic differential equation

\[
\Delta X_t = A(t) X_t \Delta W_t, \\
X(t_0) = 1, \\
t \in \mathbb{T}
\]

is called the stochastic exponential and is denoted by

\[
X_* = \mathcal{E}_A(\bullet, t_0).
\]

We note that \( \mathcal{E}_A(t,t_0) \) as a solution to (50) can be written into an integral equation

\[
\mathcal{E}_A(t,t_0) = 1 + \int_{t_0}^t A(s) \mathcal{E}_A(s, t_0) \Delta W_s, \quad \forall t \in \mathbb{T}.
\]

We will be making use of the set-up we have in Section 4 about \( \Delta \)-Itô’s formula. Let \( t_0 < t \) and \( t \in \mathbb{T} \). Let the sets \( C \) and \( \mathcal{I} \) be defined as in Section 4 corresponding to the interval \([t_0, t]\). Let \( I_k \in \mathcal{I} \) and \( I_k = (s_k^-, s_k^+) \). We note that \( s_k^- = \rho(s_k^+, s_k^+) \). Let

\[
D(t,t_0) = \sum_{I_k \in \mathcal{I}, I_k \subset [t_0, t]} A(s_k^-) (W_{s_k^+} - W_{s_k^-}) \\
- \frac{1}{2} \sum_{I_k \in \mathcal{I}, I_k \subset [t_0, t]} A^2(s_k^+) (s_k^+ - s_k^-).
\]

We define

\[
U(t,t_0) = \prod_{I_k \in \mathcal{I}, I_k \subset [t_0, t]} \left[ 1 + A(s_k^-) (W_{s_k^+} - W_{s_k^-}) \right], \\
V(t,t_0),
\]

\[
= \exp \left( \int_{t_0}^t A(s) \Delta W_s - \frac{1}{2} \int_{t_0}^t A^2(s) \Delta s - D(t,t_0) \right).
\]

Theorem 11 (stochastic exponential on time scales). The stochastic exponential has the closed-form expression

\[
\mathcal{E}_A(t,t_0) = U(t,t_0) V(t,t_0).
\]

Proof. Consider the process

\[
Y_t = \int_{t_0}^t A(s) \Delta W_s - \frac{1}{2} \int_{t_0}^t A^2(s) \Delta s - D(t,t_0).
\]

Let us introduce another function \( \alpha(t) \) such that

\[
\alpha(t) = \begin{cases} 
0, & \text{when } t = s_k^+ \text{ or } t = s_k^- \\
A(t), & \text{otherwise}.
\end{cases}
\]
We see now that the process \( Y_t \) is a solution to the \( \Delta \)-stochastic differential equation

\[
\Delta Y_t = \alpha(t) \Delta W_t - \frac{1}{2} \alpha^2(t) \Delta s,
\]

\( Y_{t_0} = 0. \) (58)

Notice that \( Y_{s_k} = Y_{s_k^+} \) for any \( I_k = (s_k^-, s_k^+) \in \mathcal{I} \). Taking this into account, as well as the fact that \( \alpha(s) = 0 \) whenever \( t = s_k^- \) or \( t = s_k^+ \), we can apply the general Itô formula (48) to the function \( V(t, t_0) = \exp(Y_t) \) and we will get

\[
\exp(Y_t) - 1 = \int_{t_0}^t \alpha(s) \exp(Y_s) \Delta W_s - \frac{1}{2} \int_{t_0}^t \alpha^2(s) \exp(Y_s) \Delta s + \frac{1}{2} \int_{t_0}^t \alpha^2(s) \exp(Y_s) \Delta s
\]

\[
= \int_{t_0}^t \alpha(s) \exp(Y_s) \Delta W_s.
\]

Thus

\[
V(t, t_0) = 1 + \int_{t_0}^t \alpha(s) V(s, t_0) \Delta W_s,
\]

or in other words

\[
\Delta V(t, t_0) = \alpha(t) V(t, t_0) \Delta W_t.
\]

Let us now consider the function \( \mathcal{E}_A(t, t_0) = U(t, t_0)V(t, t_0) \). We claim that

\[
U(t, t_0)V(t, t_0) - 1 = \int_{t_0}^t A(s) U(s, t_0) V(s, t_0) \Delta W_s.
\]

Using this fact, the above claimed identity (62) can be written as

\[
U(t, t_0) V(t, t_0) - 1 = \int_{t_0}^t \alpha(s) U(s, t_0) V(s, t_0) \Delta W_s
\]

\[
+ \sum_{t_k \in \mathcal{I}} A(s_k^+) U(s_k^+, t_0) V(s_k^+, t_0)
\]

\[
\cdot (W_{s_k^+} - W_{s_k^-}) = \int_{t_0}^t \alpha(s) U(s, t_0) V(s, t_0) \Delta W_s
\]

\[
+ \sum_{t_k \in \mathcal{I}} A(s_k^+) U(s_k^+, t_0) V(s_k^+, t_0) - U(s_k^-, t_0))
\]

\[
\cdot (W_{s_k^+} - W_{s_k^-})
\]

\[
= \sum_{t_k \in \mathcal{I}} \left[ (U(s_k^+, t_0) - U(s_k^-, t_0)) \right] = \sum_{t_k \in \mathcal{I}} (U(s_k^+, t_0) - U(s_k^-, t_0))
\]

\[
= \sum_{t_k \in \mathcal{I}} V(s_k^+, t_0) - V(s_k^-, t_0)
\]

\[
= \sum_{t_k \in \mathcal{I}} (U(s_k^+, t_0) - U(s_k^-, t_0)) = (I) + (II) + (III).
\]

Here

\[
(I) = \sum_{t_k \in \mathcal{I}} (U(s_k^+, t_0) - U(s_k^-, t_0))
\]

\[
\cdot (V(s_j, t_0) - V(s_{j-1}, t_0)),
\]

\[
(II) = \sum_{t_k \in \mathcal{I}} U(s_k^+, t_0) (V(s_j, t_0) - V(s_{j-1}, t_0))
\]

\[
(III) = \sum_{t_k \in \mathcal{I}} V(s_k^+, t_0) (U(s_j, t_0) - U(s_{j-1}, t_0))
\]

We can apply the previous arguments and classify the intervals \((s_{j-1}, s_j)\) into classes (a) and (b). Notice that, on each interval \((s_k^-, s_k^+)\), the function \(V(t, t_0)\) remains constant and the function \(U(t, t_0)\) has a jump, and on each interval \((s_{j-1}, s_j)\)
in class (a) the function \( U(t, t_0) \) is a constant. This observation and similar arguments (which we leave to the reader) as in the previous section will enable us to prove that, with probability one, as \( n \to \infty \), we will have

\[
(\text{I}) \to 0, \\
(\text{II}) \to \int_{t_0}^{t} \alpha(s) U(s, t_0) V(s, t_0) \Delta W_s, \\
(\text{III}) \to \sum_{t_k \in \mathcal{T}, t < t_k} V(s_k, t_0) \left( U(s_k, t_0) - U(s_k, t_0) \right).
\]

So we proved (65) and thus (62). \( \square \)

6. Change of Measure and Girsanov's Theorem on Time Scales

We demonstrate in this section a change of measure formula (Girsanov's formula) for Brownian motion on time scales. Our analysis is based on the method of extension that was introduced in Section 3 (originally from [2]).

Let us consider two processes: the standard Brownian motion \( \{W_t\}_{t \in \mathbb{T}} \) on \( \mathbb{T} \) and the process

\[
B_t = W_t - \int_{t_0}^{t} A(s) \Delta s,
\]

on the time scale \( t \in \mathbb{T} \).

Let us consider an extension of the (probably random) function \( A(s) \) as in (8). Let us define the so obtained extension function to be \( \tilde{A}(s) \). Recall that (8) implies that

\[
\tilde{A}(s, \omega) = A \left( \sup \{0, s\} \mathbb{T}, \omega \right).
\]

Let \( \tilde{W}_t \) be a standard Brownian motion on \([0, \infty)\). If we define

\[
\tilde{B}_t = \tilde{W}_t - \int_{t_0}^{t} \tilde{A}(s) \Delta s,
\]

then the process \( \tilde{B}_t \) agrees with \( B_t \) for any time point \( t \in \mathbb{T} \). For any \( t, t_0 \in \mathbb{T}, t > t_0 \), let

\[
\mathcal{G}_A(t, t_0) = \exp \left( \int_{t_0}^{t} \tilde{A}(s) dW_s - \frac{1}{2} \int_{t_0}^{t} \tilde{A}^2(s) \Delta s \right)
\]

\[
= \exp \left( \int_{t_0}^{t} \tilde{A}(s) dW_s - \frac{1}{2} \int_{t_0}^{t} \tilde{A}^2(s) \Delta s \right)
\]

\[
= \exp \left( \int_{t_0}^{t} A(s) \Delta W_s - \frac{1}{2} \int_{t_0}^{t} A^2(s) \Delta s \right).
\]

It is easy to see that the function \( \mathcal{G}_A(t, t_0) \) is the standard Girsanov's density function for the process \( \tilde{B}_t \) with respect to the standard Brownian motion \( \tilde{W}_t \). Since \( \tilde{B}_t \) and \( \tilde{W}_t \) have the same distributions as \( B_t \) and \( W_t \) on the time scale \( \mathbb{T} \), we conclude with the following two Theorems.

**Theorem 12** (Novikov's condition on time scales). If for every \( t \geq 0 \) one has

\[
E \exp \left( \int_{0}^{t} A^2(s) \Delta s \right) < \infty,
\]

then for every \( t \geq 0 \) one has

\[
E \mathcal{G}_A(t, t_0) = 1.
\]

Let (73) be satisfied. Let \( T > 0 \) and pick \( T > t_0, t_0, T \in \mathbb{T} \). Consider a new measure \( P^B \) on \( \mathbb{T} \), defining it Radon–Nikodym derivative with respect to \( P^W \), as

\[
dP^B = \mathcal{G}_A(T, t_0) \cdot dP^W.
\]

**Theorem 13** (Girsanov's change of measure on time scales). Under the measure \( P^B \) the process \( B_t, t \in [0, T]_{\mathbb{T}} \), is a standard Brownian motion on \( \mathbb{T} \).

7. Application to Brownian Motion on a Quantum Time Scale

In this section we are going to apply our result to a quantum time scale \( \mathbb{Q} \)-time scale, see [1, Example 4.11]. Let \( q > 1 \) and

\[
\mathbb{Q} = \{ n \in \mathbb{Z} \}_{n \in [m+1, \infty)} = \{ q^n \}_{n \in \mathbb{Z}}.
\]

The quantum time scale \( \mathbb{Q} \)-time scale is defined by \( \mathbb{Q} = \mathbb{Q}^\omega \). Given the quantum time scale \( \mathbb{Q} \), one can then construct a Brownian motion \( W_t \) on \( \mathbb{Q} \) according to Definition 3.

We have

\[
\sigma(t) = \min \{ n \in \mathbb{Z} \}_{n \in [m, \infty)} = q^n = qt
\]

if \( t \in \mathbb{N} \) and obviously \( \sigma(0) = 0 \). So we obtain

\[
\sigma(t) = qt,
\]

\[
\rho(t) = \frac{t}{q},
\]

\( \forall t \in \mathbb{Q} \)

and consequently

\[
\mu(t) = \sigma(t) - t = (q-1)t \quad \forall t \in \mathbb{Q}.
\]

Here 0 is a right-dense minimum and every other point in \( \mathbb{Q} \) is isolated. For a function \( f : \mathbb{Q} \to \mathbb{R} \) we have

\[
f^\Delta(t) = \frac{f(\sigma(t)) - f(t)}{\mu(t)} = \frac{f(qt) - f(t)}{(q-1)t}
\]

\( \forall t \in \mathbb{Q} \setminus \{0\} \),

\[
f^\Delta(0) = \lim_{s \to 0} \frac{f(0) - f(s)}{0-s} = \lim_{s \to 0} \frac{f(s) - f(0)}{s}
\]

provided the limit exists.
The open intervals $I_k$ that we have constructed in Section 4 have the form $I_k = (q^k, q^{k+1})$ where $k \in \mathbb{Z}$. For any two points $t_1 < t_2$, $t_1, t_2 \in T$, if $t_1, t_2 \neq 0$, then $t_1 = q^k$ and $t_2 = q^{k+1}$ for two integers $k_1 < k_2$. In this case we can apply (14) and we get

$$f(q^k, W_{q^k}) - f(q^{k+1}, W_{q^{k+1}}) = \int_{q^{k+1}}^{q^k} f^\Delta(s, W_s) \Delta s + \frac{1}{2} \int_{q^{k+1}}^{q^k} \frac{\partial^2 f}{\partial x^2}(s, W_s) \Delta s$$

$$+ \frac{1}{2} \sum_{k=k_1}^{k_2-1} f(q^k, W_q)(W_{q^k+1} - W_q) - \frac{1}{2} \sum_{k=k_1}^{k_2-1} \frac{\partial^2 f}{\partial x^2}(q^k, W_q)(q^{k+1} - q^k)$$

(81)

Since $T \setminus \{0\}$ is a discrete time scale, we have

$$\int_{q^{k+1}}^{q^k} \frac{\partial f}{\partial x}(s, W_s) \Delta W_s = \sum_{k=k_1}^{k_2-1} \frac{\partial f}{\partial x}(q^k, W_q)(W_{q^k+1} - W_q),$$

$$\frac{1}{2} \int_{q^{k+1}}^{q^k} \frac{\partial^2 f}{\partial x^2}(s, W_s) \Delta s = \sum_{k=k_1}^{k_2-1} \frac{\partial^2 f}{\partial x^2}(q^k, W_q)(q^{k+1} - q^k).$$

(82)

Moreover, we have

$$\int_{q^{k+1}}^{q^k} f^\Delta(s, W_s) \Delta s = \sum_{k=k_1}^{k_2-1} f(q^{k+1}, W_q) - f(q^k, W_q) (q^{k+1} - q^k)$$

$$= \sum_{k=k_1}^{k_2-1} \left[ f(q^{k+1}, W_q) - f(q^k, W_q) \right].$$

(83)

Therefore (81) becomes

$$f(q^k, W_q) - f(q^{k+1}, W_q) = \sum_{k=k_1}^{k_2-1} \left[ f(q^{k+1}, W_q) - f(q^k, W_q) \right] \quad \text{which is a trivial telescoping identity. This justifies (14) in the case away from 0.}$$

Let us consider now the case when $t_1 = 0$ and $t_2 = q^k > 0$ for some $k \in \mathbb{Z}$. In this case we have, according to (14), that

$$f(q^k, W_q) - f(0, 0) = \int_0^{q^k} f^\Delta(s, W_s) \Delta s$$

$$+ \frac{1}{2} \int_0^{q^k} \frac{\partial^2 f}{\partial x^2}(s, W_s) \Delta s$$

$$+ \sum_{j=-\infty}^{k-1} \left[ f(q^{j+1}, W_{q^{j+1}}) - f(q^j, W_{q^j}) - \frac{\partial f}{\partial x}(q^j, W_q)(W_{q^{j+1}} - W_q) - \frac{1}{2} \frac{\partial^2 f}{\partial x^2}(q^j, W_q)(q^{j+1} - q^j) \right].$$

(85)

One can justify that in this case we have

$$\int_0^{q^k} \frac{\partial f}{\partial x}(s, W_s) \Delta W_s = \sum_{j=-\infty}^{k-1} \frac{\partial f}{\partial x}(q^j, W_q)(W_{q^{j+1}} - W_q),$$

$\frac{1}{2} \int_0^{q^k} \frac{\partial^2 f}{\partial x^2}(s, W_s) \Delta s = \sum_{j=-\infty}^{k-1} \frac{1}{2} \frac{\partial^2 f}{\partial x^2}(q^j, W_q)(q^{j+1} - q^j).$$

(86)

Moreover, we have

$$\int_0^{q^k} f^\Delta(s, W_s) \Delta s = \sum_{j=-\infty}^{k-1} \frac{f(q^{j+1}, W_q) - f(q^j, W_q)}{q^{j+1} - q^j} (q^{j+1} - q^j)$$

$$= \sum_{j=-\infty}^{k-1} \left[ f(q^{j+1}, W_q) - f(q^j, W_q) \right].$$

(87)

Therefore (81) becomes

$$f(q^k, W_q) - f(0, 0) = \sum_{j=-\infty}^{k-1} \left[ f(q^{j+1}, W_q) - f(q^j, W_q) \right]$$

$$+ \sum_{j=-\infty}^{k-1} \left[ f(q^{j+1}, W_{q^{j+1}}) - f(q^j, W_{q^j}) \right]$$

$$= \sum_{j=-\infty}^{k-1} \left[ f(q^{j+1}, W_{q^{j+1}}) - f(q^j, W_{q^j}) \right].$$

(88)
which is also a telescoping identity. This justifies (14) in the case including 0.

Making use of Theorem II, it is easy to write down the stochastic exponential for the quantum time scale:

$$\mathcal{E}_A(0, q^k) = \prod_{j=-\infty}^{k-1} \left[ 1 + A(q^j) \left( W_{q^{j+1}} - W_{q^j} \right) \right].$$

Conflicts of Interest

The author declares that he has no conflicts of interest.

Acknowledgments

The author would like to express his sincere gratitude to Professor Martin Bohner for inviting him to present this work at the Time Scales Seminar, Missouri S&T, on October 5, 2016, and also for pointing out the use of delta (Hilger) derivatives. He would also like to thank Professor David Grow for an inspiring discussion on the topic. Special thanks are dedicated to Missouri University of Science and Technology (formerly University of Missouri, Rolla) for a startup fund that supports this work.
