Fascicular KNbO₃ nanowires with tetragonal perovskite structures and ultrasmall diameters are synthesized by hydrothermal route at about 150°C for 24 hours. The concentrations of medium alkalinity have influenced phase structures and the final morphologies of the products significantly by modifying the conditions in process. The as-prepared KNbO₃ nanowires exhibit three phase transitions at about 343, 454.7, and 623 K as the temperature increases from 250 to 700 K. The band gap is about 3.78 eV for KNbO₃ nanowires. Photoluminescence study at room temperature reveals two visible light emission bands peaking at ~551 and 597 nm, respectively, which may be due to the oxygen vacancies, site niobium (occupy the location of Nb), and antisite niobium (occupy the location of K) in KNbO₃ nanowires.

1. Introduction

Perovskite-type metallic oxides make a family of materials that share a common crystal structure, analogy to that of the natural crystal calcium titanate, yet exhibit a broad range of interesting physical properties [1]. With the advances in science and technology of integrated ferroelectrics, the size-dependent ferroelectric behaviors become crucial due to the dimensional confinement or the size of ferroelectrics decreasing [2]. 1D nanostructure of ferroelectric materials, such as nanorods, nanowires, and nanotubes, have attracted great attention due to their promising applications, such as miniaturized piezoelectric actuators, medical imaging detectors, and even ferroelectric memories [3, 4]. In recent years, the size-dependent physical properties, such as phase transition, polarizations, and energy band, in ferroelectric nanowires have been evaluated systematically. For instance, Naumov and Fu revealed that both the Curie temperature and the polarization of Pb(Zr₀.₅Ti₀.₅)O₃ nanowire decreased with the reducing diameter [5]. Spanier et al. reported that phase transition temperature of BaTiO₃ nanowires fell below room temperature as the diameter was ~3 nm [6]. Genust et al. found that the ferroelectric properties of BaTiO₃ nanowire vanished when the diameter was less than 1.2 nm according to the first principle calculation [7]. However, Morozovska et al. reported that the Curie temperature of ferroelectric nanorods/nanowires could be higher than that of bulk materials from a direct variational method [8]. In addition, the author revealed that there was a blue-green emission for PbTiO₃ nanowires (with diameters of 10~20 nm) both the oxygen vacancies and lead-oxygen vacancy centers may be responsible for this phenomenon [9]. Despite very promising progress in theory, there is inconsistency for phase transition as the diameter of ferroelectric nanowires is decreased. Moreover, few reports have concerned the investigation of the phase transition behavior in experiments.

Potassium niobate (KNbO₃) is one of the most important ferroelectric perovskite oxides, which undergoes successive phase transitions upon cooling from its cubic phase, that is, from cubic to tetragonal at 435°C, tetragonal to orthorhombic at 225°C, and orthorhombic to rhombohedral at ~10°C [10, 11]. This material attracts great interests for its multiple
applications, such as optical waveguides, frequency doublers, holographic storage systems, and other technological devices [12–14]. The great potential has stimulated research on the KNbO$_3$ nanowires. Therefore, the synthesis, phase transition, and optical properties of KNbO$_3$ nanowires are worth being investigated. Magrez et al. realized the growth of KNbO$_3$ nanowires with a narrow diameter distribution ∼60 nm via a hydrothermal route at 150°C from a 38.7 wt% KOH, 0.4 wt% Nb$_2$O$_5$, and 60.9 wt% H$_2$O mixture [15]. Baier-Saip et al. reported the influence of grain size on the phase transition of ferroelectric KNbO$_3$ [16]. Wang et al. found that the phase transition of orthorhombic to tetragonal and tetragonal to cubic of KNbO$_3$ nanorods with diameters of 100–300 nm occurred at lower temperatures than that of bulk counterpart due to finite size or disorder effects [17]. Nakayama et al. developed an electrode-free, continuously tunable coherent visible light source compatible with physiological environments from individual KNbO$_3$ nanowires, exhibiting efficient second harmonic generation, which could act as frequency converters, allowing the local synthesis of a wide range of colors via sum and difference frequency generations [18]. However, the diameters of the 1D nanostructure synthesized by most of the current routes are much larger than the critical size in ferroelectrics. It is still very challenging to obtain ferroelectric oxide nanowires with extremely small diameters (<10 nm) and a narrow size distribution, especially for niobate oxide. At the same time, the size effects and surface states have important impacts on the lattice distortion in the crystal, which will further result in the changes of the phase transition temperature. Thus, finding a feasible way to overcome those drawbacks discussed ahead is very essential. Herein, KNbO$_3$ nanowires with ultrathin diameters (down to 5 nm) are synthesized through two step method, that is, milling of raw materials followed by hydrothermal treatment at 150°C for 12 h. In addition, in the phase transition, room temperature photoluminescence properties of KNbO$_3$ nanowires are also investigated. The studies show that the KNbO$_3$ nanowires may be a promising candidate for fabricating piezoelectric sensors and other functional devices.

2. Experiments

2.1. Synthesis of KNbO$_3$ Nanowires. Niobium pentoxide (Nb$_2$O$_5$, 99.95%) and potassium hydroxide (KOH, 95%) were used as raw materials and C$_{12}$H$_{25}$OH as surfactant. Figure 1 shows the process illustration of KNbO$_3$ nanowires through two step hydrothermal method. Firstly, Nb$_2$O$_5$ powders of 13.29 g, KOH of 5.89 g, and C$_{12}$H$_{25}$OH of 2 g were dispersed in 80 mL C$_2$H$_5$OH together. The above mixture was milled at room temperature for 12 hours. Then the obtained precursor was dried by infrared lamp for 12 hours. After that, 20% amount of the above precursor, 20 mL C$_2$H$_5$OH, and 20 mL H$_2$O were transferred into the stainless steel autoclave (50 mL). The next step is to add 1.2 g KOH in the above mixture and stir for 30 min. Finally, KNbO$_3$ nanowires were synthesized after the mix was subjected to further hydrothermal treatment at 150°C for 12 h and cooled to room temperature.

2.2. Characterization of Materials. X-ray diffraction (XRD) measurements were performed on a Bruker AXS-D8-Advance X-ray Diffractometer system using CuKα (λ = 1.5406 Å) as the radiation source. Microstructures of the samples were determined on a field-emission scanning electron microscopy (FESEM) JEOL JSM-6700F and transmission electron microscopy (TEM) JEOL 211 using an acceleration voltage of 200 kV. The phase transition properties of KNbO$_3$ nanowires were measured using a differential scanning calorimeter (DSC, Perkin-Elmer) in the range of 250 to 700 K at a heating and cooling rate of 10.0 K/min in a nitrogen atmosphere. The UV-vis absorption spectra were measured using Shimadzu UV-2550 spectrophotometer. The fluorescence spectrum of KNbO$_3$ nanowires was recorded with Edinburgh FLSP920 fluorimeter. Fluorescence intensities were corrected for inner filter effects according to standard methods.

3. Results and Discussions

We have conducted a series of experiments with various concentrations of medium alkali, which have significant effects on the phase structures and the final morphologies of the products. We find that KNbO$_3$ nanoparticles were obtained when the total weight of NaOH reached up to 15 grams, while KNbO$_3$ nanowires were synthesized as the weight was 7.09 grams during hydrothermal treatment. Figure 1 shows the XRD pattern of KNbO$_3$ particles (a) and nanowires (b) synthesized by means of hydrothermal method, respectively. One can see that the sharp diffraction peak indicated that KNbO$_3$ particles have better crystallization than nanowires. All the diffraction peaks of them are well consistent with that of Joint Committee on Powder Diffraction Standards (JCPDS) Cards no. 71-0946 and 71-0946, respectively, illustrating clearly that the samples are composed of KNbO$_3$ perovskite structure and there is no trace of any impurity phase in the samples. It is noted that KNbO$_3$ nanoparticles have the orthorhombic structure and KNbO$_3$ nanowires belong to the tetragonal structure, which

...can be identified by the splitting peak located at $2\theta \approx 45^\circ$ (shown in the inset in Figure 1). The refined lattice parameters obtained by Curve Fitting software are determined to be $a = 4.0124(3)$ and $c = 4.0456(5)$ Å for KNbO$_3$ nanowires, while that parameters for nanoparticles are $a = 3.9966(6)$, $b = 5.6535(5)$, and $c = 5.6577(6)$ Å for nanoparticles. At the same time, the strain in the samples has been studied. The consequences imply that the strain in KNbO$_3$ nanowires is about $33 \pm 2\%$, while it is about $10 \pm 3\%$ for KNbO$_3$ nanoparticles.

The typical SEM and TEM images of the KNbO$_3$ nanowires are shown in Figure 2. As can be seen in Figure 2(a), the parallel nanowires are arranged side by side and tend to form the fascicular structure due to the Van der Waals and/or electrostatic attraction force. Almost all of the nanowires grow into regular structure and distribute uniformly in both diameter and length. As demonstrated in Figure 2(b), the TEM image exhibits a large quantity of nanowires with diameters of 5–15 nm and length of up to several micrometers. The HRTEM image in Figure 2(c) shows the lattice fringes of the sample, indicating that the KNbO$_3$ nanowires are well crystallized and structurally uniform. The adjacent lattice spacing is about 0.4114 nm, corresponding to the (001) lattice plane of KNbO$_3$. The SAED pattern (inset of Figure 2(c)), which is indexed by assuming the lattice constants refined from XRD measurements, is obtained from an entire nanowire. The result shows clear diffraction spots characteristic of crystalline KNbO$_3$, demonstrating these nanowires are growing along [001] directions.

Figure 3: DSC curve for KNbO$_3$ nanowires recorded at the temperature range from 250 to 700 K.

...will change to orthorhombic structure as the temperature reaches ~454.7 K, and it shows the rhombohedra structure when the sample is below ~343 K. However, Gopalan and Raj reported that the phase of the epitaxial KNbO$_3$ thin films would transform to be $210 \pm 10^\circ$C for orthorhombic-tetragonal and $450 \pm 10^\circ$C for tetragonal-cubic transitions, which was studied by in situ second harmonic generation measurements. It can be clearly seen that the phase transition temperature of KNbO$_3$ nanowires is much higher than that of epitaxial KNbO$_3$ thin films [19]. We consider that the obvious size and surface effect of KNbO$_3$ nanowires would have significant influences on the lattice distortion and phase transition, which may be also one of the important reasons for the differences discussed ahead.

In the earlier studies, we have found that the morphology of KNbO$_3$ nanostructures has considerable influences on the onsets of absorption. Figure 4 shows the UV-vis absorption spectrum of KNbO$_3$ nanowires dispersed in ethanol. It is clear that strong absorption happens as the wavelength is lower than 330 nm, while there is no obvious absorption band in the whole wavelength range (190–900 nm). The band gap of KNbO$_3$ nanowires is estimated to be 3.78 eV from the...
Advances in Condensed Matter Physics

4 Advances in Condensed Matter Physics

In conclusion, fascicular KNbO₃ nanowires with perovskite structures and ultrathin diameters of 5–15 nm were synthesized by hydrothermal treatment at low temperature. The KNbO₃ nanowires underwent successive phase transitions upon cooling from its cubic phase, that is, cubic $\rightarrow$ tetragonal at 623 K, tetragonal $\rightarrow$ orthorhombic at $\sim$454.7 K, and orthorhombic $\rightarrow$ rhombohedral at $\sim$343 K. The band gap of KNbO₃ nanowires is estimated to be 3.78 eV, which may be caused by the combined action of size effect and quantum size effect. There are two visible light emission peaks located at $\sim$551 nm (2.25 eV) and 597 nm (2.077 eV) for KNbO₃ nanowires at room temperature. The oxygen vacancy, the site niobium (occupy the location of Nb), and antisite niobium (occupy the location of K) may have a response for these two emissions.
