We propose that recent results by ATLAS and CMS searching for heavy resonances decaying into bosons could be a first hint of a new sector of pure gauge confining physics, possibly linked to the origin of the Higgs as a Composite Higgs. The lightest resonances (glueballs) of this new sector would be neutral, spin-zero, and spin-two, and their behaviour would resemble that of a radion and a massive graviton of extra dimensions. We outline how 13 TeV LHC data could be used to improve sensitivity on this scenario, as well as future characterization during the 13 TeV LHC run.

1. Introduction

Search for heavy resonances decaying into a pair of bosons performed by CMS and ATLAS [1–5] shows tantalizing hints towards the existence of a new resonance at a mass of around 2 TeV, a possibility which has created quite some excitement [6–21].

In this paper we provide an alternative interpretation in terms of a new strong sector, possibly linked to the origin of the Higgs particle as a composite state. We will consider new states, singlet under the SM interactions, which can be produced and decay through their coupling to the stress-energy tensor. An example of such a theory is a new pure gauge sector which undergoes confinement at energies around the TeV scale. The spectrum of this theory contains glueballs, with spin-zero and spin-two resonances at the bottom of the spectrum [22–26]. Focusing on the low-lying, conceivably narrow states, we concentrate in the scenario where the new states couple to gluons through anomalies and decay predominantly to massive vector bosons or Higgses.

2. Glueballs: Theoretical Aspects

Consider a new nonabelian gauge sector, for example, SU($n$) gauge group, which undergoes confinement leading to a low energy spectrum of glueballs. Glueballs are bound states of gauge fields and their behaviour has been studied both in the case of QCD and in the case of more general gauge theories. The ordering of states can be understood by examining the interpolating operators of minimal canonical dimension [27, 28], a prescription which lattice simulations seem to confirm [22].

With this prescription, the lightest states would then correspond to those generated by the lowest dimensional singlet operator, namely, a four-dimension operator $\text{Tr} F_{\mu\nu} F_{\rho\sigma}$, which generates glueballs with quantum numbers $J^{PC} = 0^{++}, 2^{++}, 0^{-+},$ and $2^{-+}$ (note that these quantum numbers could also be achieved within oddballs [29]).

The next level of resonances would be associated with the five-dimension operator, $\text{Tr} F_{\mu\nu} D_{\rho} F_{\alpha\beta}$, leading to resonances with quantum numbers $J^{PC} = 1^{++}$ and $3^{++}$. One could continue this procedure to classify resonances by examining six-dimension and higher operators generated by gauge fields.

In the following we are going to focus on the lowest resonances: spin-zero and spin-two. Lattice studies on SU($n$) gauge theories find that the lowest resonances correspond to PC = ++; hence we will denote them by

\[
\phi : J^{PC} = 0^{++},
\]

\[
G_{\mu\nu} : J^{PC} = 2^{++}.
\]
Determining the separation between the scalar \((0^++)\) and tensor states \((2^++)\) is a difficult task in lattice gauge theories. Lattice results in a pure glueball calculation indicates that the tensor mode is about 60% heavier than the scalar, even in the large-\(n\) limit. Nevertheless, this result will likely change once the pure gauge theory is coupled to the Standard Model. In the following, I will consider these two lightest states as two distinct possibilities for the lightest state in a glueball spectrum.

The resonances \(\phi\) and \(G\) propagate as Klein-Gordon and Fierz-Pauli [30] fields. The Fierz-Pauli Lagrangian describes a massive spin-two field, a rank-two symmetric, and traceless tensor. Additionally, a positive-energy condition must be satisfied (see [31] and references therein).

Contrary to the case of QCD, a pure gauge theory has no global (chiral) symmetries which would be broken by the confinement dynamics. On the other hand, space-time symmetries can be broken by confinement. For example, glueballs break spontaneously scale invariance of the gauge theory. Hence, the lightest spin-zero resonance could play the role of a dilaton, the Goldstone boson of the spontaneous breaking of scale invariance. In this case, the couplings of the dilaton resonance are of the form \((\phi/\Lambda) \partial_{\mu} J^\mu\), where \(J^\mu\) is the global current whose spontaneous breaking at the scale \(\Lambda\) leads to the emergence of the Goldstone boson \(\phi\). The global current is given by \(J^\mu = T^\mu_{\nu} \gamma^\nu\), where \(\gamma^\nu\) is the generator of the global symmetry. The spectrum at low energies would be SO\((5)\times SU(3)\) sector and SU\((3)\) gauge strong dynamics leading to the breaking of SO\((5)\) to SO\((4)\); see Figure 1. One could then proceed as usual in the minimal Composite Higgs scenarios, by partially gauging SO\((4)\) interactions. To achieve EWSB, one would likely need to use a mechanism as explored in [42], where the Higgs potential is generated via a sequential breaking which one could link to the standard model producing both the spin-zero and spin-two resonances and breaking the global symmetry. The spectrum at low energies would then contain the Goldstone bosons (a doublet under SU\((2)\subset SO(4)\)) and the glueballs.

In this case, the glueballs will exhibit a hierarchy of couplings. The SM particles with larger couplings to the glueballs would be the Higgs degrees of freedom through a mechanism such as partial compositeness [43–45]. As a result, the resonances of the composite sector would couple preferentially to the Higgs doublet, namely, with the Higgs particle \(h\) and the longitudinal \(W^+\) and \(Z\) bosons.

Coupings to gluons and photons would be induced through the anomaly terms, and couplings to light fermions would be suppressed by their mass. In Section 2.4 we describe how to parametrize these couplings. But before that we will discuss an alternative view in the context of extra dimensional theories, which shows the same hierarchical couplings.

### 2.2. A Set-Up for Glueballs and a Composite Higgs.

In a scenario where EWSB is due to strong dynamics, such as Composite Higgs scenarios [39–41], the glueball sector could be involved in causing the spontaneous breaking of the global symmetry responsible for the pseudo-Goldstone Higgs. In this section we explore this possibility.

Let us imagine a sector with a large global symmetry \(G\) and a gauge symmetry \(G_g\) with no fundamental fermions. Assume then that the dynamics of \(G_g\) become strong at some scale \(\Lambda\), which then triggers the spontaneous breaking of \(G\) down to a smaller subgroup \(H\). An example would be SO\((5)\times SU(3)\) sector and SU\((3)\) gauge strong dynamics leading to the breaking of SO\((5)\) to SO\((4)\); see Figure 1. One could then proceed as usual in the minimal Composite Higgs scenarios, by partly gauging SO\((4)\) interactions. To achieve EWSB, one would likely need to use a mechanism as explored in [42], where the Higgs potential is generated via a sequential breaking which one could link to the standard model producing both the spin-zero and spin-two resonances and breaking the global symmetry. The spectrum at low energies would then contain the Goldstone bosons (a doublet under SU\((2)\subset SO(4)\)) and the glueballs.

In this case, the glueballs will exhibit a hierarchy of couplings. The SM particles with larger couplings to the glueballs would be the Higgs degrees of freedom through a mechanism such as partial compositeness [43–45]. As a result, the resonances of the composite sector would couple preferentially to the Higgs doublet, namely, with the Higgs particle \(h\) and the longitudinal \(W^+\) and \(Z\) bosons.

Coupings to gluons and photons would be induced through the anomaly terms, and couplings to light fermions would be suppressed by their mass. In Section 2.4 we describe how to parametrize these couplings. But before that we will discuss an alternative view in the context of extra dimensional theories, which shows the same hierarchical couplings.

### 2.3. Holographic Radion and Graviton as Proxies for Glueballs.

Glueballs can be treated as fields arising from extra dimensions using dualities. These dualities are based on the AdS/CFT correspondence [46], which draws a duality between strongly coupled theories in \(D\) dimensions and a gravitational dual in \(D + 1\) dimensions, reaching beyond supersymmetric or exactly conformal theories [47]. The holographic duality is not an exact mathematical statement but has to be taken as a qualitative statement between strongly

Channels [1–5]. This excess is not statistically significant at the moment; hence concrete examples of specific

\[ G \rightarrow G/H \rightarrow \Phi \]

and their behaviours match in both theories in the sense that the structure of couplings of the glueballs and their holographic duals are dictated by symmetries. This dual can be used as a framework to parametrize the properties of the glueballs. Note though that there are differences between the two pictures. The 4D theory does not contain gravity; hence the holographic graviton and radion masses are unrelated to the scale of quantum gravity, which is assumed to be much higher than the physics we focus on. Also, terms involving the radion and dilaton at quadratic order may differ [59] when dilatation symmetry is not extended to gravity [60]. An extensive literature on radion/KK-graviton properties can be found elsewhere, for example, [44, 61–70].

2.4. Glueball Parametrization. In the partial compositeness picture, larger couplings between the resonances and SM particles indicate a more direct communication between the new strong dynamics and the SM sector. The hierarchy of couplings we expect is as follows [34, 57]: (1) Higgs degrees of freedom: \[ a_1, b_1 = \phi(1) \], (2) gluon and photon couplings: \[ a_{\gamma, g}, b_{\gamma, g} = \alpha_{s, \text{EM}} \gamma \] and (3) light SM fermions: \[ a_f, b_f \propto (m_f/\gamma)^\gamma \], where \( \gamma \) is some number, larger than one. In the dual extra dimensional picture, the same hierarchy of couplings has a geometrical meaning [34, 48]. The radion/KK-graviton are bulk states localized near the IR brane; hence, with larger overlap with states there, the gluon/photon are delocalized states, and light fermions are bound near the UV brane. Hence, the couplings would go as above (see [57]).

3. Glueballs at the LHC

In this section we discuss the signatures of glueballs and their interpretation in terms of the reported excess in the diboson channels [1–5]. This excess is not statistically significant at the moment; hence concrete examples of specific

Figure 1: (a) Spectrum of glueballs in a pure gauge theory, including the prior operators. The two lightest states are singled out as \( \phi (0^{++}) \) and \( G_{\mu \nu} (2^{++}) \). (b) The new sector of strong interactions exhibits a global symmetry \( G \) broken spontaneously by \( G_g \) strong dynamics.
Theoretical frameworks are useful to interpret the signatures by performing combinations of different channels. As there is no sensitivity in the fully leptonic channels and at the same time there is a sizeable overlap among the boosted hadronic $W$, $Z$, and Higgs channels, it turns out that an excess on a channel, for example, $WZ$, could be in fact due to an excess in the neutral channels.

In the following, we will assume that the total cross section into dibosons ($WW$ or $ZZ$) is of the order of $10$ fb, a number to be taken as a ballpark figure. Increasing sensitivity on this excess using the $8$ TeV LHC data would require combination of ATLAS and CMS analyses, as well as tailoring to more specific scenarios such as the one presented here.

Firstly, let us comment on bounds from precision tests of the electroweak sector, which can be parametrized with the help of $S$ and $T$ parameters [71, 72]. These bounds on composite $G$ and $\phi$ can be obtained from [73, 74] with suitable modifications. In both cases, the contribution to electroweak observables is induced at loop level. Assuming there is no Higgs-$\phi$ mixing term, the contribution to $S$ parameter due to $\phi$ is scaled as $S_\phi \propto \alpha_\phi^2 \Lambda^2$, whereas the spin-two state is $S_G \approx \frac{\alpha_\phi^2 \Lambda^2}{4\pi \Lambda^2}$ [73]. Both contributions also receive a logarithmic enhancement. As the coupling of $G_{\mu\nu}$ to longitudinal $W$ and $Z$ is through their mass, $aT = 0$ at one loop.

3.1. Branching Ratios and Total Width. The partial widths of the $2^+$ state to Higgs degrees of freedom take the following form: $\Gamma(G \rightarrow W^+W^-)/2 = \Gamma(G \rightarrow ZZ) = \Gamma(G \rightarrow hh) = (b_h(3\Lambda^2/16\pi)(m_h^2/\Lambda^2))$. The partial width to gluons would be given by $\Gamma(G \rightarrow gg) = (a_g^2/2\pi \Lambda^2)(m_g^2/\Lambda^2)$ and $\Gamma(G \rightarrow VBF) = (b_g^2/120\pi \Lambda^2)(m_g^2/\Lambda^2)$.

Therefore, the resonances remain narrow as long as $\Lambda \geq m_{h,G}$. Assuming $a_{h1}$ and $b_{h1}$ are the largest couplings, the total width would be given by a simple expression: $\Gamma_h = (a_{h1}^2/4\pi)(m_g^2/\Lambda^2)$ and $\Gamma_G = (b_{g1}^2/240\pi)(m_g^2/\Lambda^2)$.

3.2. Production Cross Section. The production of the glueballs is dominated by gluon fusion ($ggF$) and possibly vector boson fusion ($VBF$), as couplings to light fermions are very suppressed. Whether $ggF$ or $VBF$ is the dominant production mechanism depends on the suppression of couplings to gluons with respect to $W$ and $Z$ couplings, that is, the value of the coefficients $(a_g$ and $b_g)$ and $(a_{h1}$ and $b_{h1}$), respectively. The production cross section through gluon fusion and $VBF$ is given by Table 1, in the range $m_{h,G} = 2 – 1.8$ TeV. Vector boson fusion is kinematically suppressed, although it is enhanced by couplings to Higgs degrees of freedom, $a_{h1}$ and $b_{h1}$. Note that the $VBF$ 13 TeV LHC is more steep for the spin-two resonance.

In Figure 2 we show the total cross sections at 8 TeV LHC for the spin-zero and spin-two hypothesis in the $HV$ and $VV$ channels.
channels and digluon final state. As one can see, the spin-two resonance remains narrow in a larger region of the parameter space, a behaviour which is related to the kinematic features discussed in the next section. These numbers have been obtained by implementing the glueballs in the context of \texttt{feynrules} [75], exported to \texttt{Madgraph5} [76] using the \texttt{UFO} [77] format.

The coupling of the glueball $\phi$ to gluons, photons, and vector bosons has the same Lorentz structure as the Higgs (see (2) and (3)), whereas the spin-two resonance has a more interesting Lorentz structure. In particular, the Feynman rule (in the unitary gauge) involving this resonance with vector bosons is given by [57]

$$
\left[ G_{\mu\nu}, V_a \left( k_1 \right), V_{\beta} \left( k_2 \right) \right]:
- \frac{i}{\Lambda} \left( b_2 m_{\gamma}^2 C_{\mu\nu,a\beta} + b_\gamma W_{\mu\nu,a\beta} \right),
$$

where

$$
W_{\mu
u,a\beta} \equiv \eta_{a\beta} k_1 \cdot k_2 + \eta_{\mu a} \left( k_1 \cdot k_2 \eta_{\nu\beta} - k_1 \cdot k_2 \right)
- \eta_{\mu \beta} k_1 \cdot k_2 + \frac{1}{2} \eta_{\nu a} \left( k_1 \cdot k_2 - k_1 \cdot k_2 \eta_{\rho\beta} \right)
+ \left( \mu \leftrightarrow \nu \right),
$$

and $V$ here denotes either a massive vector boson ($b_\gamma \neq 0$) or a massless gluon or photon ($b_\gamma = 0$). We have discussed how the lightest states, massivespin-zero and spin-two resonances, could inherit their couplings from the breaking of diffeomorphism invariance due to the strong dynamics. They would then behave in a similar way as expected from a radion and a massive Kaluza-Klein resonance of extra dimensions.

The higher spin resonance exhibits more boosted spectrum due to the different Lorentz structure of the coupling; see [78–82] for a discussion in the context of the Higgs candidate. Therefore, criteria such as mass drop or mass reconstruction will depend on the spin of the resonance. The spin of the resonance determines not only the $p_T$ spectrum but also angular distributions. We leave for a future study [83] a more realistic analysis of this scenario within a feasibility study at Les Houches.

\section{Discussion of the Results}

The Run1 data has been able to probe diboson production in the very boosted regime, providing a tantalizing hint of new physics at around 2 TeV. How fast and reliably this hint can be confirmed or discarded depends on contrasting the signatures with specific models. Combination of different diboson channels as well as with dijet, ditop, and Higgs-vector boson relies on benchmarks against which the analyses can be tested. Besides trivial issues of branching ratios to specific final states, the analysis depends on whether a resonance is gluon, quark, or vector boson initiated and its quantum numbers, as they determine how the decay products are distributed.

In this paper we have such benchmark of interpretation in the context of glueballs of a new strong sector. We have discussed how the lightest states, massive spin-zero and spin-two resonances, could inherit their couplings from the breaking of diffeomorphism invariance due to the strong dynamics. They would then behave in a similar way as expected from a radion and a massive Kaluza-Klein resonance of extra dimensions.

If the new sector dynamics are linked to EWSB, the resonances will couple preferentially to Higgs degrees of freedom, that is, the Higgs and longitudinal polarizations of $W$ and $Z$ bosons, whereas the best way to produce them is through gluon fusion with a possible vector boson fusion component.

Regarding the collider analysis, the results presented here are performed at parton level. A more detailed analysis, including prospects to measure properties with 13 TeV LHC, will be done in a future publication [83].

\section{Additional Points}

After this paper was written, new results from the Run2 LHC looking for the diboson resonance show no significant excess in the region around 2 TeV. More data in the summer of 2016 would be required to determine whether the Run1 excess is ruled out by a larger Run2 dataset.
Competing Interests
