Bonome et al., 1997, provided an algebraic characterization for an indefinite Sasakian manifold to reduce to a space of constant $\overline{\phi}$-holomorphic sectional curvature. In this present paper, we generalize the same characterization for indefinite $g \cdot f \cdot f$-space forms.

1. Introduction

For an almost Hermitian manifold $(M^{2n}, g, J)$ with $\dim(M) = 2n > 4$, Tanno [1] has proved the following.

**Theorem 1.1.** Let $\dim(M) = 2n > 4$, and assume that almost Hermitian manifold $(M^{2n}, g, J)$ satisfies

$$R(JX, JY, JZ, JX) = R(X, Y, Z, X)$$

(1.1)

for every tangent vector $X, Y, Z$. Then $(M^{2n}, g, J)$ has a constant holomorphic sectional curvature at $x$ if and only if

$$R(X, JX)X \text{ is proportional to } JX$$

(1.2)

for every tangent vector $X$ at $x \in M$.

Tanno [1] has also proved an analogous theorem for Sasakian manifolds as follows.
**Theorem 1.2.** A Sasakian manifold $n > 5$ has a constant $\phi$-sectional curvature if and only if

$$R(X,\phi X)X \text{ is proportional to } \phi X$$

for every tangent vector $X$ such that $g(X,\xi) = 0$.

Nagaich [2] has proved the generalized version of Theorem 1.1, for indefinite almost Hermitian manifolds as follows.

**Theorem 1.3.** Let $(\mathbb{M}^n, g, J)$ ($n > 2$) be an indefinite almost Hermitian manifold that satisfies (1.1), then $(\mathbb{M}^n, g, J)$ has a constant holomorphic sectional curvature at $x$ if and only if

$$R(X,JX)X \text{ is proportional to } JX$$

for every tangent vector $X$ at $x \in M$.

Bonome et al. [3] generalized Theorem 1.2 for an indefinite Sasakian manifold as follows.

**Theorem 1.4.** Let $(\mathbb{M}^{2n+1}, \phi, \eta, \xi, g)$ ($n \geq 2$) be an indefinite Sasakian manifold. Then $\mathbb{M}^{2n+1}$ has a constant $\phi$-sectional curvature if and only if

$$R(X,\phi X)X \text{ is proportional to } \phi X$$

for every vector field $X$ such that $g(X,\xi) = 0$.

In this paper, we generalize Theorem 1.4 for an indefinite generalized $g \cdot f \cdot f$-space form by proving the following.

**Theorem 1.5.** Let $(\mathbb{M}^{2n+r}, f_1, f_2, \mathcal{F})$ be an indefinite generalized $g \cdot f \cdot f$-space form. Then $\mathbb{M}^{2n+r}$ is of constant $\phi$-sectional curvature if and only if

$$\not{R}(X,\phi X)X \text{ is proportional to } \phi X$$

for every vector field $X$ such that $\not{g}(X,\xi) = 0$, for any $\alpha \in \{1, \ldots, r\}$.

**2. Preliminaries**

A manifold $\mathbb{M}$ is called a globally framed $f$-manifold (or $g \cdot f \cdot f$-manifold) if it is endowed with a nonnull $(1,1)$-tensor field $\phi$ of constant rank, such that $\ker \phi$ is parallelizable; that is, there exist global vector fields $\xi_\alpha$, $\alpha \in \{1, \ldots, r\}$, with their dual 1-forms $\eta^\alpha$, satisfying $\phi^2 = -I + \sum_{\alpha=1}^r \eta^\alpha \otimes \xi_\alpha$ and $\eta^\alpha(\xi_\beta) = \delta^\alpha_\beta$. 
The $g \cdot f \cdot f$-manifold $(\overline{M}^{2n+r}, \overline{\Phi}, \overline{\xi}, \overline{\eta})$, $\alpha \in \{1, \ldots, r\}$, is said to be an indefinite metric $g \cdot f \cdot f$-manifold if $\overline{\Phi}$ is a semi-Riemannian metric with index $\nu$ $(0 < \nu < 2n + r)$ satisfying the following compatibility condition:

$$\overline{g}(\overline{\Phi}X, \overline{\Phi}Y) = \overline{g}(X, Y) - \sum_{\alpha = 1}^{r} \epsilon_\alpha \overline{\eta}^\alpha(X) \overline{\eta}^\alpha(Y),$$

(2.1)

for any $X, Y \in \Gamma(T\overline{M})$, being $\epsilon_\alpha = \pm 1$ according to whether $\overline{\xi}_\alpha$ is spacelike or timelike. Then, for any $\alpha \in \{1, \ldots, r\}$, one has $\overline{\eta}^\alpha(X) = \epsilon_\alpha \overline{g}(X, \overline{\xi}_\alpha)$. Following the notations in [4, 5], we adopt the curvature tensor $R$, and thus we have $R(X, Y, Z) = \nabla_X \nabla_Y Z - \nabla_Y \nabla_X Z - \nabla_{[X,Y]} Z$ and $\overline{R}(X, Y, Z, W) = \overline{g}(\overline{R}(Z, W, Y), X)$, for any $X, Y, Z, W \in \Gamma(T\overline{M})$.

We recall that, as proved in [6], the Levi-Civita connection $\overline{\nabla}$ of an indefinite $g \cdot f \cdot f$-manifold satisfies the following formula:

$$2\overline{g}\left((\overline{\nabla}_X \overline{\Phi}) Y, Z\right) = 3d\Phi(X, \overline{\Phi}Y, \overline{\Phi}Z) - 3d\Phi(X, Y, Z) + \overline{g}(N(Y, Z), \overline{\Phi}X) + \epsilon_\alpha N^\alpha(Y, Z) \overline{\eta}^\alpha(X) + 2\epsilon_\alpha d\overline{\eta}^\alpha(\overline{\Phi} Y, X) \overline{\eta}^\alpha(Z) - 2\epsilon_\alpha d\overline{\eta}^\alpha(\overline{\Phi} Z, X) \overline{\eta}^\alpha(Y),$$

(2.2)

where $N^\alpha$ is given by $N^\alpha(X, Y) = 2d\overline{\eta}^\alpha(\overline{\Phi} X, Y) - 2d\overline{\eta}^\alpha(\overline{\Phi} Y, X)$.

An indefinite metric $g \cdot f \cdot f$-manifold is called an indefinite $S$-manifold if it is normal and $d\overline{\eta}^\alpha = \Phi$, for any $\alpha \in \{1, \ldots, r\}$, where $\Phi(X, Y) = \overline{g}(X, \overline{\Phi} Y)$ for any $X, Y \in \Gamma(T\overline{M})$. The normality condition is expressed by the vanishing of the tensor field $N = N^\Phi + \sum_{\alpha = 1}^{r} 2d\overline{\eta}^\alpha \otimes \overline{\xi}_\alpha$, $N^\Phi$ being the Nijenhuis torsion of $\overline{\Phi}$.

Furthermore, the Levi-Civita connection of an indefinite $S$-manifold satisfies

$$\left(\overline{\nabla}_X \overline{\Phi}\right) Y = \overline{g}(\overline{\Phi} X, \overline{\Phi} Y) \overline{\xi} + \overline{\eta}(Y) \overline{\Phi}^2(X),$$

(2.3)

where $\overline{\xi} = \sum_{\alpha = 1}^{r} \overline{\xi}_\alpha$ and $\overline{\eta} = \sum_{\alpha = 1}^{r} \epsilon_\alpha \overline{\eta}^\alpha$. We recall that $\overline{\nabla}_X \overline{\xi}_\alpha = -\epsilon_\alpha \overline{\Phi} X$ and $\ker \overline{\Phi}$ is an integrable flat distribution since $\overline{\nabla}_{\overline{\xi}_\alpha} \overline{\xi}_\beta = 0$ (see more details in [6]).

A plane section in $T_p\overline{M}$ is a $\overline{\Phi}$-holomorphic section if there exists a vector $X \in T_p\overline{M}$ orthogonal to $\overline{\xi}_t, \ldots, \overline{\xi}_r$ such that $\{X, \overline{\Phi}X\}$ span the section. The sectional curvature of a $\overline{\Phi}$-holomorphic section, denoted by $c(X) = R(X, \overline{\Phi}X, \overline{\Phi}X, X)$, is called a $\overline{\Phi}$-holomorphic sectional curvature.
Proposition 2.1 (see [7]). An indefinite Sasakian manifold \( (\overline{M}^{2n+1}, \overline{\varphi}, \overline{\xi}, \overline{\eta}, \overline{g}) \) has \( \overline{\varphi} \)-sectional curvature \( c \) if and only if its curvature tensor verifies

\[
\overline{R}(X, Y) = \frac{(c + 3)e}{4} \left\{ \overline{\varphi}(Y, Z)X - \overline{\varphi}(X, Z)Y \right\}
+ \frac{(c - 1)}{4} \left\{ \overline{\varphi}(X, Z)\overline{\varphi}Y - \overline{\varphi}(Y, Z)\overline{\varphi}X + 2\overline{\varphi}(X, Y)\overline{\varphi}Z \\
- \overline{\varphi}(Z, Y)\overline{\eta}(X)\overline{\xi} + \overline{\varphi}(Z, X)\overline{\eta}(Y)\overline{\xi} - \overline{\eta}(Y)\overline{\eta}(Z)X + \overline{\eta}(Z)\overline{\eta}(X)Y \right\}
\]

(2.4)

for any vector fields \( X, Y, Z, W \in \Gamma(\overline{T}\overline{M}) \).

A Sasakian manifold \( \overline{M}^{2n+1} \) with constant \( \overline{\varphi} \)-sectional curvature \( c \in \mathbb{R} \) is called a Sasakian space form, denoted by \( \overline{M}^{2n+1}(c) \).

Definition 2.2. An almost contact metric manifold \( (\overline{M}^{2n+1}, \overline{\varphi}, \overline{\xi}, \overline{\eta}, \overline{g}) \) is an indefinite generalized Sasakian space form, denoted by \( \overline{M}^{2n+1}(f_1, f_2, f_3) \), if it admits three smooth functions \( f_1, f_2, f_3 \) such that its curvature tensor field verifies

\[
\overline{R}(X, Y) = f_1 \left\{ \overline{\varphi}(Y, Z)X - \overline{\varphi}(X, Z)Y \right\}
+ f_2 \left\{ \overline{\varphi}(X, Z)\overline{\varphi}Y - \overline{\varphi}(Y, Z)\overline{\varphi}X + 2\overline{\varphi}(X, Y)\overline{\varphi}Z \right\}
+ f_3 \left\{ -\overline{\varphi}(Z, Y)\overline{\eta}(X)\overline{\xi} + \overline{\varphi}(Z, X)\overline{\eta}(Y)\overline{\xi} - \overline{\eta}(Y)\overline{\eta}(Z)X + \overline{\eta}(Z)\overline{\eta}(X)Y \right\}
\]

(2.5)

for any vector fields \( X, Y, Z, W \in \Gamma(\overline{T}\overline{M}) \).

Remark 2.3. Any indefinite generalized Sasakian space form has \( \overline{\varphi} \)-sectional curvature \( c = f_1 + 3f_2 \). Indeed, \( f_1 = (c + 3)/4 \) and \( f_2 = f_3 = (c - 1)/4 \).

Proposition 2.4 (see [6]). An indefinite \( S \)-manifold \( \overline{M}^{2n+r} \) has \( \overline{\varphi} \)-sectional curvature \( c \) if and only if its curvature tensor verifies

\[
\overline{R}(X, Y) = \frac{(c + 3e)}{4} \left\{ \overline{\varphi}(Y, Z)\overline{\varphi}X - \overline{\varphi}(X, Z)\overline{\varphi}Y \right\}
+ \frac{(c - e)}{4} \left\{ \overline{\varphi}(Z, Y)\overline{\varphi}X - \overline{\varphi}(Z, X)\overline{\varphi}Y + 2\overline{\varphi}(X, Y)\overline{\varphi}Z \right\}
+ \left\{ \overline{\eta}(Z)\overline{\eta}(X)\overline{\varphi}Y - \overline{\eta}(Y)\overline{\eta}(Z)\overline{\varphi}X + \overline{\varphi}(Z, \overline{\varphi}Y)\overline{\eta}(X)\overline{\xi} - \overline{\varphi}(Z, \overline{\varphi}X)\overline{\eta}(Y)\overline{\xi} \right\}
\]

(2.6)

for any vector fields \( X, Y, Z, W \in \Gamma(\overline{T}\overline{M}) \) and \( e = \sum e_\alpha \).
An indefinite $S$-manifold $\mathbb{M}^{2n+r}$ with constant $\Phi$-sectional curvature $c \in \mathbb{R}$ is called a $S$-space form, denoted by $\mathbb{M}^{2n+r}(c)$. One remarks that for $r = 1$, $2.6$ reduces to $2.4$.

3. An Indefinite Generalized $g \cdot f \cdot f$-Manifold

Let $\mathcal{F}$ denote any set of smooth functions $F_{ij}$ on $\mathbb{M}^{2n+r}$ such that $F_{ij} = F_{ji}$ for any $i,j \in \{1, \ldots, r\}$.

**Definition 3.1.** An indefinite generalized $g \cdot f \cdot f$-space-form, denoted by $(\mathbb{M}^{2n+r}, F_1, F_2, \mathcal{F})$, is an indefinite $g \cdot f \cdot f$-manifold $(\mathbb{M}^{2n+r}, \Phi, \overline{\phi}, \overline{\eta}^i, \underline{\Phi})$ which admits smooth function $F_1, F_2, \mathcal{F}$ such that its curvature tensor field verifies

$$\overline{R}(X,Y)Z = F_1 \left\{ \overline{\Phi}(\overline{\phi}X, \overline{\phi}Z) \overline{\Phi}^2 Y - \overline{\Phi}(\overline{\phi}Y, \overline{\phi}Z) \overline{\Phi}^2 X \right\}$$

$$+ F_2 \left\{ \Phi(Z,Y)\overline{\phi}X - \Phi(Z,X)\overline{\phi}Y + 2\Phi(X,Y)\overline{\phi}Z \right\}$$

$$+ \sum_{\alpha, \beta=1}^r F_{\alpha\beta} \left\{ \overline{\eta}^\alpha(X)\overline{\eta}^\beta(Z) \overline{\Phi}^2 Y - \overline{\eta}^\alpha(Y)\overline{\eta}^\beta(Z) \overline{\Phi}^2 X \right\}$$

$$+ \overline{\Phi}(\overline{\phi}Z, \overline{\phi}Y)\overline{\eta}^\alpha(X)\overline{\phi}Z - \overline{\Phi}(\overline{\phi}Z, \overline{\phi}X)\overline{\eta}^\alpha(Y)\overline{\phi}Z \right\}$$

(3.1)

for any vector fields $X, Y, Z, W \in \Gamma(T\mathbb{M})$.

For $r = 1$, we obtain an indefinite Sasakian space form $\mathbb{M}^{2n+1}(f_1, f_2, f_3)$ with $f_1 = F_1$, $f_2 = F_2$, and $f_3 = F_1 - F_{11}$. In particular, if the given structure is Sasakian, (3.1) holds with $F_{11} = 1, F_1 = (c + 3)/4, F_3 = (c - 1)/4$, and $f_3 = F_1 - F_{11} = (c - 1)/4 = f_2$.

**Theorem 3.2.** Let $(\mathbb{M}^{2n+r}, F_1, F_2, \mathcal{F})$ be an indefinite generalized $g \cdot f \cdot f$-space form. Then $\mathbb{M}^{2n+r}$ is of constant $\Phi$-sectional curvature if and only if

$$\overline{R}(X, \overline{\phi}X)X \text{ is proportional to } \overline{\phi}X \tag{3.2}$$

for every vector field $X$ such that $\overline{\Phi}(X, \overline{\phi}z_a) = 0$, for any $a \in \{1, \ldots, r\}$.

**Proof.** Let $(\mathbb{M}^{2n+r}, F_1, F_2, \mathcal{F})$ be an indefinite generalized $g \cdot f \cdot f$-space form. To prove the theorem for $n \geq 2$, we will consider cases when $n = 2$ and when $n > 2$, that is, when $n \geq 3$.

**Case 1** ($\overline{\Phi}(X, X) = \overline{\Phi}(Y, Y)$). The proof is similar as given by Lee and Jin [8], so we drop the proof.

**Case 2** ($\overline{\Phi}(X, X) = -\overline{\Phi}(Y, Y)$). Here, if $X$ is spacelike, then $Y$ is timelike or vice versa. First of all, assume that $\mathbb{M}$ is of constant $\Phi$-holomorphic sectional curvature. Then (3.1) gives

$$\overline{R}(X, \overline{\phi}X)X = \{F_1 + 3F_2\} \overline{\phi}X = c\overline{\phi}X. \tag{3.3}$$
Conversely, let \( \{X, Y\} \) be an orthonormal pair of tangent vectors such that \( \overline{g}(\overline{\phi}X, Y) = \overline{g}(X, \overline{\phi}Y) = 0 \), and \( n \geq 3 \). Then \( X = (X + iY)/\sqrt{2} \) and \( Y = (i\overline{\phi}X + \overline{\phi}Y)/\sqrt{2} \) also form an orthonormal pair of tangent vectors such that \( \overline{g}(\overline{\phi}X, \overline{\phi}Y) = 0 \). Then (3.1) and curvature properties give

\[
0 = \overline{R}(\overline{X}, \overline{\phi}X, \overline{Y}, \overline{X})
= \overline{g}\left( \overline{R}(X, \overline{\phi}X)X, \overline{\phi}X \right) - \overline{g}\left( \overline{R}(Y, \overline{\phi}Y)Y, \overline{\phi}Y \right) - 2\overline{g}\left( \overline{R}(X, \overline{\phi}Y)Y, \overline{\phi}Y \right) + 2\overline{g}\left( \overline{R}(X, \overline{\phi}X)Y, \overline{\phi}X \right). \tag{3.4}
\]

From the assumption, we see that the last two terms of the right-hand side vanish. Therefore, we get \( c(X) = c(Y) \).

Now, if \( \text{span}\{U, V\} \) is \( \overline{\phi} \)-holomorphic, then for \( \overline{\phi}U = aU + bV \), where \( a \) and \( b \) are constant, we have

\[
\text{span}\left\{U, \overline{\phi}U\right\} = \text{span}\{U, aU + bV\} = \text{span}\{U, V\}. \tag{3.5}
\]

Similarly,

\[
\text{span}\left\{V, \overline{\phi}V\right\} = \text{span}\{U, V\}, \quad \text{span}\left\{U, \overline{\phi}U\right\} = \text{span}\{V, \overline{\phi}V\}. \tag{3.6}
\]

These imply

\[
\overline{R}(U, \overline{\phi}U, U, \overline{\phi}U) = \overline{R}(V, \overline{\phi}V, V, \overline{\phi}V), \quad \text{or} \quad c(U) = c(V). \tag{3.7}
\]

If \( \text{span}\{U, V\} \) is not \( \overline{\phi} \)-holomorphic section, then we can choose unit vectors \( X \in \text{span}\{U, \overline{\phi}U\}^\perp \) and \( Y \in \text{span}\{V, \overline{\phi}V\}^\perp \) such that \( \text{span}\{X, Y\} \) is \( \overline{\phi} \)-holomorphic. Thus we get

\[
c(U) = c(X) = c(Y) = c(V), \tag{3.8}
\]

which shows that any \( \overline{\phi} \)-holomorphic section has the same \( \overline{\phi} \)-holomorphic sectional curvature.
Now, let $n = 2$, and let \( \{X, Y\} \) be a set of orthonormal vectors such that \( \overline{g}(X, X) = -\overline{g}(Y, Y) \) and \( \overline{g}(X, \overline{\phi} X) = 0 \), and we have \( c(X) = c(Y) \) as before. Using the property (3.2), we get

\[
R(X, \overline{\phi} X)X = -\{F_1 + 3F_2\} \overline{\phi} X = -c(X) \overline{\phi} X,
R(X, \overline{\phi} X)Y = -2F_2 \overline{\phi} Y,
R(X, \overline{\phi} Y)X = -F_1 \overline{\phi} Y,
R(X, \overline{\phi} Y)Y = F_2 \overline{\phi} X,
R(Y, \overline{\phi} X)Y = F_1 \overline{\phi} X,
R(Y, \overline{\phi} Y)X = -F_2 \overline{\phi} Y,
R(Y, \overline{\phi} Y)Y = 2F_2 \overline{\phi} X,
\]

\[
R(Y, \overline{\phi} Y)Y = \{F_1 + 3F_2\} \overline{\phi} = c(Y) \overline{\phi} Y = c(X) \overline{\phi} Y.
\]

Now, define \( \tilde{X} = aX + bY \) such that \( a^2 - b^2 = 1 \) and \( a^2 \neq b^2 \). Using the above relations, we get

\[
R(\tilde{X}, \overline{\phi} \tilde{X})\tilde{X} = C_1 \overline{\phi} X + C_2 \overline{\phi} Y.
\]

Therefore, we have

\[
C_1 = -a^3 c(X) + ab^2 c(X),
C_2 = b^3 c(X) - a^2 bc(X).
\]

On the other hand,

\[
R(\tilde{X}, \overline{\phi} \tilde{X})\tilde{X} = c(\tilde{X}) \overline{\phi} \tilde{X} = c(\tilde{X}) \{a \overline{\phi} X + b \overline{\phi} Y\}.
\]

Comparing (3.11) and (3.12), we get

\[
-a^2 c(X) + b^2 c(X) = c(\tilde{X}),
b^2 c(X) - a^2 c(X) = c(\tilde{X}).
\]
On solving (3.13), we have

\[ c(X) = c(\bar{X}). \]  

(3.14)

Similarly, we can prove

\[ c(Y) = c(\bar{Y}). \]  

(3.15)

Therefore, \( \mathcal{M} \) has constant \( \bar{\phi} \)-holomorphic sectional curvature.

**Case 3** \( (\mathcal{G}(\mathcal{U},\mathcal{U}) = 0) \). It is enough to show a sufficient condition. Let \( Y_\alpha \) be a unit vector tangent to \( \xi_\alpha \), for any \( \alpha \in \{1, \ldots, r\} \), such that \( \mathcal{G}(Y_\alpha, Y_\alpha) = -\mathcal{G}(\xi_\alpha, \xi_\alpha) = -c_\alpha \), and consider the null vector \( U_\alpha = \xi_\alpha + Y_\alpha \). From (3.2),

\[
c(U_\alpha)\bar{\phi}U_\alpha = c(U_\alpha)\bar{\phi}(\xi_\alpha + Y_\alpha)
= \mathcal{R}(\xi_\alpha + Y_\alpha, \bar{\phi}(\xi_\alpha + Y_\alpha))(\xi_\alpha + Y_\alpha).
\]  

(3.16)

Therefore,

\[
c(U_\alpha) = \mathcal{G}(c(U_\alpha)\bar{\phi}(\xi_\alpha + Y_\alpha), c_\alpha Y_\alpha)
= \rho c(U_\alpha)\bar{\phi}(\xi_\alpha + Y_\alpha) + \epsilon_\alpha \mathcal{G}(Y_\alpha, \bar{\phi}Y_\alpha)
+ \epsilon_\alpha \mathcal{G}(\bar{\phi}(\xi_\alpha + Y_\alpha)Y_\alpha, \bar{\phi}Y_\alpha)
+ \epsilon_\alpha \mathcal{G}(\bar{\phi}(\xi_\alpha + Y_\alpha)Y_\alpha, \bar{\phi}Y_\alpha)
+ \epsilon_\alpha \mathcal{G}(\bar{\phi}(\xi_\alpha + Y_\alpha)Y_\alpha, \bar{\phi}Y_\alpha)
+ \epsilon_\alpha \mathcal{G}(\bar{\phi}(\xi_\alpha + Y_\alpha)Y_\alpha, \bar{\phi}Y_\alpha)
\]  

(3.17)

From Cases 1 and 2, depending on the sign of \( \epsilon_\alpha \), \( \mathcal{G}(\bar{\phi}(Y_\alpha, \bar{\phi}Y_\alpha)Y_\alpha, \bar{\phi}Y_\alpha) = \epsilon_\alpha c(Y_\alpha) \) is constant, and hence \( c(U_\alpha) = c(Y_\alpha) \) is constant.
Theorem 3.3 (see [9]). Let \((M^{2n+r}, \bar{\theta}, \bar{\eta}, \bar{\xi}, \bar{\gamma}) (n \geq 2)\) be an indefinite \(S\)-manifold. Then \(M^{2n+r}\) is of constant \(\phi\)-sectional curvature if and only if

\[
R(X, \phi X)X \text{ is proportional to } \phi X
\]  
(3.18)

for every vector field \(X\) such that \(g(X, \xi_\alpha) = 0\), for any \(\alpha \in \{1, \ldots, r\}\).

Proof. An \(S\)-space form is a special case of \(g \cdot f \cdot f\)-space form, and hence the proof follows from Theorem 3.2 and (2.6).

Theorem 3.4 (cf. Bonome et al. [3]). Let \((M^{2n+1}, \phi, \eta, \xi, g) (n \geq 2)\) be an indefinite Sasakian manifold. Then \(M^{2n+1}\) is of constant \(\phi\)-sectional curvature if and only if

\[
R(X, \phi X)X \text{ is proportional to } \phi X
\]  
(3.19)

for every vector field \(X\) such that \(g(X, \xi) = 0\).

Proof. When \(r = 1\), an indefinite \(S\)-space form \(M^{2n+1}(c)\) reduces to a Sasakian space form. The proof follows from (2.4) and Theorem 3.3.
