Background. Atherosclerosis is characterized by endothelial dysfunction, vascular inflammation, and the buildup of lipids, cholesterol, calcium, and cellular debris within the intima of the walls of large and medium size arteries. Objective. To evaluate the effect of clopidogrel on atherosclerosis progression. Materials and Methods. A total of 28 local domestic rabbits were assigned to four groups: normal control, atherogenic control, vehicle control, and clopidogrel treated. Serum triglycerides, total cholesterol, HDL-C, plasma high sensitive C-reactive protein (hsCRP), plasma malondialdehyde (MDA), and plasma reduced glutathione (GSH) were measured at the end of the experiment. Immunohistochemical analysis showed that aortic expressions of VCAM-1, MCP-1, TNF-α, and IL-17A were significantly increased in atherogenic control group. Histopathologic finding showed that animals on atherogenic diet have significant atherosclerotic lesion. Compared to atherogenic control group clopidogrel do not have significant effect on lipid profile. Clopidogrel significantly reduces hsCRP and MDA levels and increases GSH level. Furthermore, clopidogrel treatment significantly reduced aortic expressions parameters and the histopathologic examination of the aortic arch showed a significant reduction of atherosclerotic lesion. Conclusions. This study outlines how clopidogrel reduces lipid peroxidation, systemic inflammation, and aortic expression of inflammatory markers and hence reduces the progression of atherosclerosis.

1. Introduction

Atherosclerosis is a disease of large- and medium-sized arteries and is characterized by endothelial dysfunction, vascular inflammation, and the buildup of lipids, cholesterol, calcium, and cellular debris within the intima of the vessel wall. This buildup results in plaque formation, vascular remodelling, acute and chronic luminal obstruction, abnormalities of blood flow, and diminished oxygen supply to target organs [1]. The proposed initial step in atherogenesis is endothelial dysfunction leading to a number of compensatory responses that alter the normal vascular homeostatic properties [2]. Proinflammatory stimuli, including a diet high in saturated fat, hypercholesterolemia, obesity, hyperglycemia, insulin resistance, hypertension, and smoking, trigger the endothelial expression of adhesion molecules such as P-selectin, E-selectin, ICAM-1, and VCAM-1 which mediate the attachment of circulating monocytes and lymphocyte [3, 4]. Atherosclerotic lesions develop as a result of inflammatory stimuli, subsequent release of various cytokines, proliferation of smooth muscle cells, synthesis of connective tissue matrix, and accumulation of macrophage and lipid. Atherosclerosis is likely initiated when endothelial cells overexpress adhesion molecules in response to turbulent flow in the setting of an unfavorable serum lipid profile. Clopidogrel inhibits ADP receptors on platelets, blocking GPIIb/IIIa complex and as a result, inhibiting platelet aggregation. Animals that were fed a pro-atherogenic diet rapidly overexpress vascular cell adhesion molecule-1 (VCAM-1) [5]. VCAM-1 expression increases recruitment
of monocytes and T cells to sites of endothelial injury; subsequent release of monocyte chemotactrant protein-1 (MCP-1) by leukocytes magnifies the inflammatory cascade by recruiting additional leukocytes, activating leukocytes in the media, and causing recruitment and proliferation of smooth muscle cells [6]. However, in response to signals generated within the early plaque, monocytes adhere to the endothelium and then migrate through the endothelium and basement membrane by elaborating enzymes, including locally activated matrix metallopeptinase (MMP) that degrade the connective tissue matrix. Recruited macrophages both release additional cytokines and begin to migrate through the endothelial surface into media of the vessel. This process is further enhanced by the local release of monocytes-colony stimulating factor (M-CSF), which causes monocyctic proliferation; local activation of monocytes leads to both cytokine-mediated progression of atherosclerosis and oxidation of low-density lipoprotein (LDL) [7]. Platelets serve major functions in three key aspects of atherosclerosis: atherogenesis, inflammation, and homeostatic [8]. Therefore, the present study was undertaken to evaluate the effect of clopidogrel on the progression of atherosclerosis.

2. Materials and Methods

2.1. Animals. A total of 28 local domestic rabbits, weighing (1.1–1.5) kg, were used in this study. All experiments were conducted in the Department of Pharmacology, College of Medicine, Qadaysia University, according to the guidelines for the Care and Use of Laboratory Animals in scientific research. The animals were placed in an animal house, in a group caging system, at controlled temperature (25 ± 2°C) and ambient humidity. Lights were maintained on a 12-h light/dark cycle. The animals had free access to water ad libitum.

2.2. Drugs. Clopidogrel (plavix, sanofi aventis, BN.F-33565, France) was dissolved in ethanol (10%) [9] and used in a dose of 20 mg/kg/day [10]. A solution of drug was freshly prepared and administered once daily orally according to body weight through stomach tube.

2.3. Animal Model of Atherosclerosis. Induction of atherosclerosis was carried out by feeding the rabbit an atherogenic diet (2% cholesterol (BDH Chemicals Ltd Poole England, prod 43011) enriched rabbit chow) made by addition of cholesterol powder to chick pellets for 8 weeks [11,12].

2.4. Experimental Protocol. After 2 weeks of acclimatization period, the animals were randomized into 4 groups of 7 rabbits each: normal diet control group (NC, Group I), high-cholesterol diet group which served as atherogenic control (AC, Group II), high-cholesterol diet with ethanol group (vehicle, Group III), and high-cholesterol diet with clopidogrel group (Group IV). The NC group was fed normal rabbit chow, whereas the high-cholesterol diet groups were fed a 2% high-cholesterol (atherogenic) diet. The duration of treatment was 8 weeks. At the end of the experiment, food was withheld for 16–18 hours and animals were anesthetized by ketamine (HIKMA Pharmaceuticals B.N 3310) at 66 mg/kg and xylazine (alfasan B.N 100411-07) at 6 mg/kg intramuscular [13]. The chest was opened by thoracotomy, blood sample was collected directly from the heart, and aorta was separated. After that, the following investigations were performed:

(i) lipid profile including total serum cholesterol (TC), low density lipoprotein (LDL), and high density lipoprotein (HDL),
(ii) immunohistochemistry for assessment of VCAM, TNFα, MCP1 and IL-17A,
(iii) oxidation parameter including MDA and GSH,
(iv) systemic inflammatory marker hsCRP,
(v) histopathological examination of the aorta for assessment of atherosclerosis.

All specimens were immediately fixed in 10% formaldehyde solution for subsequent processing.

2.5. Biochemical Procedures. Serum lipid profile, including total cholesterol and TG, was determined by enzymatic methods using an automatic analyzer (Abbott, Alcyon 300, USA). Plasma GSH levels was determined using methods of Beutler [14]. Plasma MDA level were determined by using competitive inhibition enzyme immunoassay technique (cusabio; Catalog no. CSB-E13712Rb). The determination of hsCRP was done by using rabbit high-sensitive CRP ELISA kit supplied by (Kamiya Biomedical Company; Cat. no. KT-097). The measurement was carried out according to the manufacturer’s instructions.

2.6. Histological Examination of the Aorta. For histological evaluation of atherosclerosis, the specimens were processed in usual manner and embedded in paraffin and cut into 5-μm thick sections. The tissue sections were stained with hematoxylin and eosin. The assessment of atherosclerotic changes was performed according to the American Heart Association classification of atherosclerosis: Type I and Type II lesions (early lesions), Type III lesions (intermediate lesions or preatheroma), Type IV lesions (atheroma), Type V lesions (fibroatheroma or advance lesion), and Type VI lesions (complicated lesions) [15] (Figure 1).

2.7. Immunohistochemistry. It was performed with polyclonal goat antibodies and raised against rabbit VCAM-1, TNFα, MCP-1, and IL-17A. Staining procedure was carried out according to the manufacturer’s instructions (Santa Cruz Biotechnology, Inc). The stain intensity was scored to 0: indicated no staining, 1: weak, 2: moderate, 3: strong, and 4: very strong stain intensity [16] (Figures 2, 3, 4, and 5).

2.8. Statistical Analysis. Statistical analyses were performed using SPSS 12.0 version. Data were expressed as mean ± SEM. Paired t-test was used to compare the mean values within each group at different time. Analysis of Variance (ANOVA)
Figure 1: A cross section of aortic arch from hypercholesterolemic rabbit represented atherosclerosis progression (×40). (a) Normal arterial appearance, (b) initial atherosclerotic lesion characterized by lipid laden macrophage (foam cells), (c) intermediate atherosclerotic lesion characterized by extracellular lipid pool, (d) advance atherosclerotic lesion characterized by core of extracellular lipid, and (e) complicated atherosclerotic lesion characterized by haemorrhagic thrombus.

was used for the multiple comparison among all groups. The histopathological grading was assessed by Mann-Whitney test. In all tests, \( P < 0.05 \) was considered to be statistically significant.

3. Results

3.1. Effect of High-Cholesterol Diet. There was no statistically significant difference between AC group and vehicle group. Compared to NC group, the AC showed significant changes in serum lipid profile, oxidation, and inflammatory markers. Serum levels of TC, TG and LDL-C as well as plasma levels of MDA and hs-CRP were significantly \( (P < 0.001) \) increased. In addition plasma levels of GSH were significantly \( (P < 0.001) \) lower in rabbits that fed on cholesterol-enriched diet in comparison to animals on normal diet (Tables 1, 2, and 3).

3.2. Effects of Clopidogrel Treatment. Compared to atherogenic control, treating hyperlipidemic rabbits with clopidogrel resulted in significantly \( (P < 0.001) \) lower levels of plasma hs-CRP and MDA. However, clopidogrel treatment
caused no significant alteration ($P > 0.05$) in the levels of serum lipids and GSH (Tables 2 and 3).

3.3. **Immunohistochemistry.** The results of immunohistochemical analysis for rabbit’s aortic arch of VCAM-1, MCP-1, TNF-alpha, and IL-17A were significantly different between the 4 study groups. The median intensity of these markers was the highest in AC group (very strong for all markers) and the lowest in NC group (normal for all markers). Clopidogrel treated group was associated with a median stain intensity of moderate for VCAM-1, MCP-1, TNF-alpha, and IL-17A that is significantly lower than the atherogenic control (Figure 6).

3.4. **Histopathological Findings.** The atherosclerotic lesions of aortic arch were graded as normal, initial, intermediated, advance, and complicated lesions (Figure 1). The median

4. Discussion

4.1. Effect of Clopidogrel on Lipid Profile. In this study clopidogrel had small nonsignificant effect on lipid profile in comparison with induced untreated study group. Such findings are consistent with that of Gu and his followers [17].
4.2. Effect of Clopidogrel on Oxidation Stress and Inflammatory Parameters. Like what Srinivas and his followers concluded in 2008 [18], the results showed that clopidogrel had significant effect on plasma MDA and GSH levels. Clopidogrel inhibited the increased plasma MDA level in AC group and it increased the plasma GSH level that was lowered in AC group. Furthermore, the results demonstrated a significant effect of clopidogrel on inflammatory acute phase protein by reducing the elevated hsCRP in rabbits on high fat diet. This finding suggests that the anti-inflammatory activity of clopidogrel...
on the vascular inflammatory responses is induced by high fat diet. This hypothesis is supported by similar findings and conclusions of other researchers [19, 20].

4.3. Effect of Clopidogrel on Aortic Expression of Immunohistochemistry Parameters (VCAM-1, MCP-1, TNF-α, and IL-17).

The significant reduction of elevated VCAM-1, MCP-1, TNF-α, IL-17 in atherosclerosis model of hypercholesterolemia rabbit shows the effect of clopidogrel on such inflammatory markers. This finding was also reported by Li and his followers [21]. So, clopidogrel can reduce inflammation that underlies the chronic process of atherosclerosis by
