The aim of this study was to evaluate the activity of fluconazole against 32 clinical strains of fluconazole-resistant Candida albicans, and C. albicans ATCC 10231 reference strain, after their exposure to sublethal concentrations of tea tree oil (TTO) or its main bioactive component terpinen-4-ol. For all tested fluconazole-resistant C. albicans strains TTO and terpinen-4-ol minimal inhibitory concentrations (MICs) were low, ranging from 0.06% to 0.5%. The 24-hour exposure of fluconazole-resistant C. albicans strains to fluconazole with sublethal dose of TTO enhanced fluconazole activity against these strains. Overall, 62.5% of isolates were classified as susceptible, 25.0% exhibited intermediate susceptibility, and 12.5% were resistant. For all of the tested clinical strains the fluconazole MIC decreased from an average of 244.0 μg/mL to an average of 38.46 μg/mL, and the fluconazole minimal fungicidal concentrations (MFC) decreased from an average of 254.67 μg/mL to an average of 66.62 μg/mL. Terpinen-4-ol was found to be more active than TTO, and strongly enhanced fluconazole activity against fluconazole-resistant C. albicans strains. The results of this study demonstrate that combining natural substances such as TTO and conventional drug such as fluconazole, may help treat difficult yeast infections.

1. Introduction

Essential oils are antiseptic substances produced by plants. Tea tree oil (TTO) is the essential oil obtained by steam distillation from the Australian native plant Melaleuca alternifolia and is used medicinally as a topical antiseptic. It has a broad spectrum of antimicrobial activity against a wide range of bacteria, viruses, and fungi, including yeasts and dermatophytes. TTO is a mixture of more than 100 different compounds, primarily terpenes (mainly monoterpenes and sesquiterpenes). The physical properties and chemical composition of TTO are variable, and it is, therefore, important to determine international standards. The Australian Standard for tea tree oil (AS 2782-1985) includes directives relating to the levels of two components: the minimum content of terpinen-4-ol should be at least 30% and the maximum content of 1,8-cineole should be less than 15% of the oil volume [1]. The international standard for tea tree oil (ISO 4730:2004) includes maximum and minimum percentage values for the 15 most important TTO components. TTO obtained by steam distillation of the leaves and terminal branches of Melaleuca alternifolia Cheel, Melaleuca linariifolia Smith, Melaleuca dissitiflora F. Mueller, and other species of Melaleuca should conform to this standard [2].

TTO has been used for centuries in Australian folk medicine, predominantly for wound treatment [3, 4]. In the 1920s, Penfold described for the first time the properties and chemical composition of TTO, and he later confirmed the antiseptic properties of TTO and its components [5–8]. In the 1930s, consecutive publications appeared which demonstrated the powerful antimicrobial activity of TTO when used in inhalation therapy, aseptic surgery, dental surgery, wound disinfection, and oral cavity rinsing [9–11].

Currently, TTO is used as a local agent for treating various diseases, predominantly dermatoses (e.g., recurrent herpes labialis, acne, pustules, dandruff, and rash). TTO is also used
to treat *Staphylococcus aureus* infections of the oral cavity and the pharynx, vaginitis, and respiratory tract diseases. Numerous studies have confirmed the broad antimicrobial activity of TTO against bacteria, fungi, and viruses, as well as microorganisms that are resistant to conventional drugs [12–16]. This is important due to the increase in infections that are difficult to treat, as TTO can be used as an alternative to or in combination with conventional drugs (including antibiotics and chemotherapeutic agents).

Treatment of infections can be based on monotherapy (using one antimicrobial drug) or combined therapy (two or more drugs). The primary aim of combined therapy is to enhance the action of the drugs while decreasing the dosages, through synergism. When monotherapy or combined therapy based on conventional drugs is unsuccessful, then combined treatment including a natural agent may be more effective. Several recent studies have reported the increased antimicrobial activity of natural substances combined with conventional drugs as compared to conventional drug treatment alone [17–20].

The aim of this study was to evaluate the activity of fluconazole against clinical strains of fluconazole-resistant *Candida albicans* and reference strain *C. albicans* ATCC 10231, after their exposure to sublethal concentrations of TTO or its main bioactive component terpinen-4-ol.

### 2. Materials and Methods

#### 2.1. *Candida albicans* Strains. This study included 32 clinical *Candida albicans* strains, which were isolated from the following materials: swabs of the pharynx and oral cavity (*n* = 5), vagina (*n* = 15), sputum (*n* = 8), or faeces (*n* = 4). These strains were isolated from culture on Sabouraud agar (bioMérieux, Marcy l’Etoile, France), and species identification was performed using the biochemical test ID 32C (bioMérieux, Marcy l’Etoile, France). We also used the reference strain *C. albicans* ATCC 10231, which was purchased from Oxo Ltd. (Basingstoke, Great Britain). We previously determined the sensitivity of *C. albicans* strains to fluconazole by the Kirby-Bauer disk diffusion susceptibility test [21] using 6 mm filter paper disks impregnated with 10 μg of fluconazole obtained from DHN (Cracow, Poland) and YNB agar (Yeast Nitrogen Base-Difco 0.5%, glucose 3%, agar 1.8%, pH = 7) also obtained from DHN (Cracow, Poland). The *C. albicans* strains were classified as exhibiting susceptibility (diameter of growth inhibition zone ≥18 mm), intermediate susceptibility (diameter of growth inhibition zone from 14 mm to 17 mm), or resistance (diameter of growth inhibition zone <14 mm) to fluconazole (the data were described in chapter 3). The fluconazole MIC (minimal inhibitory concentration) and MFC (minimal fungicidal concentration) values were determined by the broth dilution method according to the Clinical and Laboratory Standards Institute (CLSI document M27-A3-2008) [22]. Using this standard, the *C. albicans* strains were classified as exhibiting susceptibility (MIC ≤ 8 μg/mL), intermediate susceptibility (MIC from 9 μg/mL to 63 μg/mL), or resistance (MIC ≥ 64 μg/mL) to fluconazole (the data were presented in chapter 3).

#### 2.2. Tea Tree Oil (TTO). In this study, we used Australian tea tree oil (*Melaleuca alternifolia*) from Thursday Plantation (Integria Healthcare, Eight Mile Plains, QLD, Australia) series 270930 that conforms to the ISO standard 4730:2004 [2] (Table I). TTO was distilled from specially selected *Melaleuca alternifolia* leaves, a plant native to the coastal regions of northern New South Wales and south eastern Queensland in Australia. The analysis of TTO composition was carried out by gas chromatography according to the international standard ISO 4730 [2]. It was performed in the following conditions: fused-silica column (50 m × 0.20 mm i.d., film thickness 0.25 μm) and flame ionisation type of detector were used, the carrier gas was hydrogen (flow rate of 1 mL/min), the oven temperature programme was from 70°C to 220°C at a rate of 2°C/min, the injector temperature was 230°C, the detector temperature was 250°C, the volume of injected TTO was 0.2 μL, and the split ratio was 1:100.

In our study, we also used terpinen-4-ol, which was obtained from Sigma-Aldrich (St. Louis, MO, USA).

#### 2.3. Fluconazole. In this study, we used the antifungal drug fluconazole (Polfarmex, Kutno, Poland). The structure of the fluconazole molecule is shown in Figure 1.

#### 2.4. Preparation of the Initial *Candida albicans* Suspension. *C. albicans* cells cultured for 24 h on Sabouraud agar were suspended in a saline solution (0.85% NaCl) and adjusted to a 0.5 McFarland density standard (1.5 × 10⁶ CFU/mL). This suspension was later diluted to a density of 6 × 10⁵ CFU/mL. The suspension was then used to estimate the MIC and MFC values for TTO, terpinen-4-ol, and fluconazole.
BioMed Research International

2.5. Determination of MIC and MFC Values for TTO and Terpinen-4-ol. The TTO activity against the C. albicans strains tested was determined by broth macrodilution using the general dilution standards as described by PN-EN ISO 20776-1:2007 [24]. TTO was serially diluted in liquid Sabouraud medium with 10% Tween 80 to final TTO concentrations of 1% to 0.0075%. The Tween 80 detergent helps dissolve the TTO. The same volume of the C. albicans suspension was added to each tube to obtain a final density of $3 \times 10^3$ CFU/mL. After 24 h of incubation at 35°C, the cell growth was assessed visually in the tubes with TTO and the positive control tube (without TTO). The MIC was defined as the lowest concentration of TTO that led to no visible growth of the cell strains tested. The MFC value was defined as the lowest concentration of TTO that showed no growth of C. albicans colonies. The experiment was performed triply. The terpinen-4-ol MIC and MFC values were determined identically as described above. The TTO and terpinen-4-ol MICs were used to calculate the sublethal doses of TTO and terpinen-4-ol used in the following experiments.

2.6. Brief Pretreatment of Candida albicans with 1/4 MIC TTO. For each sample, a tube was prepared containing saline solution with 10% Tween 80 and TTO to a final concentration of 1/4 MIC TTO. A control tube with no TTO was also prepared. Next, the C. albicans suspension was added to tubes to obtain a final density of $3 \times 10^3$ CFU/mL. The suspensions were then incubated at 35°C for 30 minutes. The samples were then rinsed twice and centrifuged between rinses (3000 xg, 15 minutes), and the cells were resuspended to a density of $6 \times 10^4$ CFU/mL. The suspension was then used to determine the fluconazole MIC and the minimal fungicidal concentration (MFC) of fluconazole. The study was performed in triplicate.

2.7. Determination of the Fluconazole MIC and MFC Values after Brief Pretreatment of Candida albicans with 1/4 MIC TTO. The fluconazole activity against the C. albicans strains tested was determined by broth macrodilution using the general dilution standards as described by PN-EN ISO 20776-1:2007 [24]. Serial, parallel dilutions of fluconazole ranging from 256.0 μg/mL to 0.125 μg/mL were prepared in liquid Sabouraud medium, and a control tube without the drug was included. For each of the tubes, the same volume of C. albicans cells suspension pretreated with 1/4 MIC TTO was added, and the inoculum was adjusted to a final density of $3 \times 10^3$ CFU/mL. After 24 h of incubation at 35°C, the cell growth in each tube was assessed visually. The MIC value was defined as the lowest concentration of fluconazole that resulted in no visible growth of the strains tested. The cells from the tube identified as the MIC, as well as several of the surrounding dilutions, were plated to Sabouraud agar. After 24 h of incubation at 35°C, the C. albicans colonies were counted. The MFC value was defined as the lowest concentration of fluconazole that showed no growth of C. albicans colonies. The experiment was performed in triplicate. The C. albicans strains were classified as exhibiting susceptibility, intermediate susceptibility, or resistance to fluconazole according to CLSI document M27-A3-2008 [22], as described in Section 2.1.

2.8. Prolonged Pretreatment of Candida albicans with Fluconazole and Sublethal Dose of TTO or Terpinen-4-ol. Serial, parallel dilutions of fluconazole ranging from 256.0 μg/mL to 0.125 μg/mL were prepared in liquid Sabouraud culture medium. Two positive controls were included. All tubes contained 10% Tween 80, and TTO was added to each dilution and one of the control tubes to achieve a final concentration of 1/4 MIC TTO. The second control tube contained only the liquid medium. Next, an equal volume of C. albicans suspension was added to each tube to a final density of $3 \times 10^3$ CFU/mL. All the tubes were incubated at 35°C for 24 h. After incubation, the cell growth in each tube was evaluated visually, and the fluconazole MIC and MFC values were defined, as described previously. The cells from the tube identified as the MIC, as well as several of the surrounding dilutions, were plated to Sabouraud agar. After 24 h of incubation at 35°C, the C. albicans colonies were counted, and the fluconazole MFC value was defined. The experiment was performed in triplicate. The prolonged pretreatment of C. albicans with fluconazole and terpinen-4-ol was performed identically as described above.

2.9. Statistical Methods. The results are presented as the arithmetic mean and the median. The statistical differences between the mean values were determined by Student’s t-test and the Mann-Whitney U test, depending on how well the results correlated with a normal distribution. Values of $P \leq 0.05$ were considered statistically significant. The programme STATISTICA version 10 (StatSoft, Cracow, Poland) was used to perform the statistical analyses.

3. Results

The Candida albicans strains tested were resistant to fluconazole and susceptible to low concentrations of TTO. The clinical C. albicans strains and C. albicans ATCC 10231
reference strain, tested by the Kirby-Bauer disk diffusion susceptibility test, did not exhibit the zone of inhibition of growth. All the studied *C. albicans* strains were classified as exhibiting resistance to fluconazole. The fluconazole MIC values for the 32 clinical *C. albicans* strains ranged from 64.0 μg/mL to 256.0 μg/mL (average = 244.0 ± 47.22 μg/mL). The most common values were 256.0 μg/mL (30 strains) and 64.0 μg/mL (2 strains). For *C. albicans* ATCC 10231 reference strain the fluconazole MIC was 256.0 μg/mL.

The TTO MICs for the 32 clinical *C. albicans* strains ranged from 0.06% to 0.5% (average = 0.19 ± 0.09%). The most common values were 0.125% (15 strains) and 0.25% (15 strains). The TTO MICs of the two remaining strains were 0.06% and 0.5%. For *C. albicans* ATCC 10231 reference strain, the TTO MIC was 0.125%. These results indicate that the *C. albicans* strains tested did not exhibit any cross-resistance to TTO and fluconazole. The TTO MIC values were used to calculate the sublethal doses (1/4 MIC TTO) used in the rest of the study.

The brief pretreatment of 32 clinical *C. albicans* strains and of *C. albicans* ATCC 10231 reference strain with 1/4 MIC TTO did not change the fluconazole MIC and MFC values. Exposing *C. albicans* strains to 1/4 MIC TTO and fluconazole for 24 hours (prolonged pretreatment) significantly increased susceptibility yeast strains to fluconazole. Out of 32 fluconazole-resistant *C. albicans* clinical strains, 28 strains (87.5%) exhibited then high or intermediate susceptibility to fluconazole (Table 2).

 Exposure of fluconazole-resistant *C. albicans* strains for 24 h to 1/4 MIC TTO and fluconazole enhanced fluconazole activity against these strains. Overall, 62.5% of isolates were classified as susceptible, 25.0% exhibited intermediate susceptibility, and 12.5% were resistant. For all of the tested clinical strains, the average fluconazole MIC decreased from 244.0 μg/mL to 38.46 μg/mL after this prolonged pretreatment, and the average fluconazole MFC decreased from 254.67 μg/mL to 66.62 μg/mL (Table 3). The MIC and MFC values for the susceptible strains (n = 20) and strains with intermediate susceptibility (n = 8) were statistically low compared to the analogous values obtained for the control sample and for the samples that were only briefly pretreated with TTO. For the group of susceptible isolates, the fluconazole MIC decreased to an average of 0.52 μg/mL, and the fluconazole MFC decreased to an average of 4.25 μg/mL. Prolonged pretreatment of *Candida albicans* ATCC 10231 standard strain with 1/4 MIC TTO and fluconazole did not increase the susceptibility of this strain to fluconazole, like the four fluconazole-resistant clinical *C. albicans* strains studied. Terpinen-4-ol, the main bioactive component present in TTO, strongly enhanced fluconazole activity against fluconazole-resistant *C. albicans* strains. The terpinen-4-ol MICs for clinical *C. albicans* strains ranged from 0.06% to 0.25% (average = 0.11 ± 0.09%). For *C. albicans* ATCC 10231 standard strain, the terpinen-4-ol MIC was 0.06%. The *C. albicans* strains tested did not exhibit any cross-resistance to terpinen-4-ol and fluconazole. Exposure of fluconazole-resistant clinical and standard *C. albicans* strains for 24 h to fluconazole and sublethal doses (1/4 MIC) of terpinen-4-ol strongly enhanced fluconazole activity against these strains, and all of *C. albicans* isolates were classified as susceptible (fluconazole MIC decreased to 0.125 μg/mL). We summed up the results of this study, and the most important data are presented in a table form (Table 4).

4. Discussion

TTO is the most commonly used essential oil for its antibacterial and antifungal properties [3, 25]. In this study, we evaluated the change in fluconazole activity *in vitro* against fluconazole-resistant clinical *Candida albicans* strains exposed to the sublethal concentrations of TTO or terpinen-4-ol, the main bioactive component of TTO. The earlier *in vitro* studies of the sensitivity of *Candida* spp. to TTO have shown that TTO is highly active against these microbes, as well as azole-resistant strains, for which the TTO MICs ranged from 0.25% to 0.5% [14, 26]. For the *C. albicans* strains that were resistant to both fluconazole and itraconazole, the TTO MICs ranged from 0.25 to 1.0%, the TTO MIC50 was 0.5%, and the TTO MIC90 was 1% [27]. Another study showed that three fluconazole-resistant clinical *C. albicans* strains had very low TTO MICs (0.15% for two strains and 0.07% for the third strain) [15].

The experiments performed in this study confirm the results from previously published studies in that all of the tested fluconazole-resistant *C. albicans* strains were sensitive to TTO [14, 15, 28, 29]. The determined TTO MICs were low, ranging from 0.06% to 0.5%. The TTO antimicrobial activity is attributed mainly to terpinen-4-ol, the main bioactive component present in TTO [3, 14]. The determined MIC values for terpinen-4-ol were very low, ranging from 0.06% to 0.25%. Our study and other studies show that *C. albicans* does not exhibit cross-resistance to TTO and azole agents [14, 15, 26, 27]. Clinical resistance to TTO has not been reported. Multicomponent nature of TTO may reduce the potential for resistance to occur spontaneously, and multiple simultaneous mutations may be required to overcome all of

the antimicrobial actions of each of the components [3]. Thus, TTO can be used as a topical antiseptic to effectively treat superficial mycoses caused by fluconazole-resistant Candida spp. and other azole-resistant yeast. Unfortunately, TTO can be potentially toxic when it is ingested in high doses, and, therefore, TTO should not be administrated orally. The acute oral toxicity of TTO is similar to the oral toxicity of other common essential oils, for example, such as eucalyptus oil [30, 31]. The lipophilic nature of TTO, which enables it to penetrate the outer layers of skin, potentiates not only the antiseptic actions but also the possibility of TTO toxicity due to dermal absorption. TTO can cause skin irritation at higher concentrations and may cause allergic reactions in predisposed individuals [3, 31, 32]. Zhang and Robertson observed ototoxic effect of 100% TTO [33]. The toxicity of TTO is dose-dependent, and the majority of adverse events can be avoided through the use of TTO in a diluted form [31]. TTO is not mutagenic or genotoxic [34, 35].

There is increasing interest not only in the activity of natural substances against resistant microbes but also in the synergistic interactions between these substances and conventional drugs [19, 20, 36–38]. Fluconazole is one of the azole antifungal agents widely used for both prophylaxis and therapy of Candida infections [39–41]. In this study, we explored changes in the activity of fluconazole against fluconazole-resistant C. albicans strains after exposure to sublethal concentrations of TTO or terpinen-4-ol. We used exclusively fluconazole-resistant strains because identifying synergistic treatments for these strains would be especially important. We tested sublethal concentrations of TTO and terpinen-4-ol because we expected concentrations lower than the MIC to weaken the cell structure without killing the cells, facilitating the activity of fluconazole and consequently inhibiting C. albicans resistance to fluconazole. Our results show that brief (0.5 h) exposure of fluconazole-resistant C. albicans strains to sublethal concentration of TTO (1/4 MIC TTO) had no influence on the antifungal activity of fluconazole. However, exposing C. albicans cells to sublethal concentration of TTO and then treating them with fluconazole inhibited the resistance to fluconazole in 87.5% of the tested strains. These results suggest that there is a synergistic interaction between fluconazole and TTO against fluconazole-resistant C. albicans. TTO was used to permeabilise the yeast cell membranes, markedly increasing the susceptibility to fluconazole. The TTO becomes embedded in the lipid bilayer membrane, which disrupts its structure, resulting in increased permeability and impaired physiological function. TTO also inhibits the formation of germ tubes or mycelial conversion in C. albicans and inhibits respiration in C. albicans in dose-dependent manner [3]. Fungal cells exposed to TTO will eventually rupture. Sublethal concentrations of TTO also weaken Candida spp. cells vitality [41, 42]. The mechanism of fluconazole antifungal activity is different. It was demonstrated that fluconazole interferes with the cytochrome P-450-dependent enzyme C-14α-demethylase, which is responsible for production of ergosterol. The disruption of ergosterol synthesis causes structural and functional changes in the fungal cell membrane, which predispose the fungus cells to damage. Inhibition of cytochrome c oxidase and peroxidative enzymes is an additional antifungal activity of fluconazole [39]. Several mechanisms have been described for fluconazole resistance in C. albicans isolates: increased production of lanosterol 14α-demethylase encoded by ERG11 gene and decreases in the affinity of lanosterol 14α-demethylase for fluconazole because of mutations in ERG11 gene and a defect in Δ5-6 desaturase encoded by ERG3 gene causing loss of function in the ergosterol pathway. The other mechanism of fluconazole resistance in C. albicans is the active transport of drugs across the plasma membrane by “efflux pumps,” which requires the expression of the CDR1/2 and MDRI genes [39, 43–47]. TTO-induced cell membrane damage can disrupt the function of “efflux pumps,” thus making the fungal cell more susceptible to fluconazole [48, 49].

Our data show that there is a synergistic effect in vitro of sublethal concentrations of TTO and fluconazole against fluconazole-resistant C. albicans strains. However, the fluconazole-resistant C. albicans ATCC 10231 standard strain and four clinical C. albicans strains did not increase the susceptibility to fluconazole. The differences in mechanisms of resistance of these strains to fluconazole were probable cause of this effect. In our in vitro study the TTO main component terpinen-4-ol was more active than TTO and strongly enhanced fluconazole activity against all studied fluconazole-resistant C. albicans strains. Mondello et al. [14] as well as

### Table 4: MIC and MFC values of fluconazole, TTO, terpinen-4-ol, and fluconazole with TTO or terpinen-4-ol, for fluconazole-resistant Candida albicans strains.

Ninomiya et al. [50] observed that in vivo TTO and terpinen-4-ol were similarly effective against candidiasis caused by azole-resistant C. albicans. The mechanisms underlying the synergy between fluconazole and TTO did not elucidate. Yu et al. [51] confirmed the synergism between fluconazole and triclosan against clinical isolates of fluconazole-resistant C. albicans. Liu et al. [52] observed synergistic effect between fluconazole and glabridin against C. albicans related to the effect of glabridin on cell envelope. Ahmad et al. [53] described synergistic activity of thymol and carvacrol with fluconazole against Candida isolates. Both monoterpenes inhibited efflux by 70–90% showing their high potency to block drug transporter pumps.

Previous studies also have evaluated the activity of TTO against various microorganisms in combination with other antimicrobial substances. A synergistic effect was observed for itraconazole and TTO in a thermosensitive gel used to treat vaginal candidiasis [26]. Synergistic effects have also been observed between essential oils and ciprofloxacin, gentamicin, cefixime, and pristinamycin [20]. In a disc diffusion test using C. albicans, C. glabrata, C. tropicalis, C. krusei, C. guilliermondii, and C. parapsilosis, larger growth inhibition zones occurred around discs impregnated with TTO and amphotericin B than around discs containing only TTO [17]. In a study of Staphylococcus aureus, larger zones of growth inhibition occurred around discs impregnated with TTO and other essential oils compared to discs impregnated with TTO only [54].

The synergistic action of antimicrobial substances has also been shown using time-kill curves. The short pretreatment of Pseudomonas aeruginosa with a substance that disrupts the cytoplasmic membrane (carboxyl cyanide m-chlorophenylhydrazone, polymyxin B nonapeptide, or ethylenediaminetetraacetic acid) enhanced the bactericidal activity of TTO, as demonstrated by the increased speed of microbe killing in the time-kill curves [55, 56]. However, in a study using the E-test method, Escherichia coli, Salmonella enteritidis, Salmonella typhimurium, Staphylococcus aureus, and coagulase-negative staphylococci (CoNS) exposed to sublethal concentrations of TTO for 72 hours exhibited increased resistance to gentamicin, streptomycin, chloramphenicol, tetracycline, erythromycin, trimethoprim, ampicillin, fusidic acid, mupirocin, linezolid, and vancomycin [57, 58]. Increased antimicrobial activity was observed when essential oils were combined with their isolated components (e.g., terpinen-4-ol from Melaleuca alternifolia) [59] and when TTO was combined with silver ions [60, 61].

The fractional inhibition concentration (FIC) index, also referred to as the FICI, is used to determine whether two substances are synergistic or antagonistic. FIC values can be interpreted differently, however, in general, an FIC index lower than 0.5 indicates synergism and an FIC index higher than 4 indicates antagonism [18, 19, 38, 59]. The FIC index value for TTO and tobramycin was 0.37 for Escherichia coli and 0.62 for Staphylococcus aureus, indicating that these two substances are synergistic [19]. A minor synergistic effect was observed when treating Candida albicans with TTO and amphotericin B and Klebsiella pneumoniae with TTO and ciprofloxacin. TTO and ciprofloxacin exhibit antagonistic effects against Staphylococcus aureus [18]. There is no synergistic effect between TTO and lysostaphin, mupirocin, gentamicin, or vancomycin against methicillin-resistant Staphylococcus aureus strains. In fact, the FIC index indicated that TTO and vancomycin are antagonistic [38].

The results of this study and other previous studies demonstrate that combining natural substances such as TTO and conventional drugs such as fluconazole may help treat difficult yeast infections. However, additional in vitro studies are needed to identify the antimicrobial activity of natural medicinal substances and detect synergistic interactions with commonly used antimicrobial agents.

Conflict of Interests

The authors declare that there is no conflict of interests regarding the publication of this paper.

Acknowledgments

The authors would like to thank the MELALEUCA company in Gliwice (Poland) for kindly donating the Australian tea tree oil obtained from Melaleuca alternifolia, the Polfarmex company in Kutno (Poland) for kindly donating the fluconazole, and the LABOMED Microbiological Laboratory in Gliwice (Poland) for kindly providing the clinical Candida albicans strains used in this study.
