Cytomegalovirus infection in a patient with Crohn’s ileocolitis

Sahin Coban MD1, Arzu Ensari MD2, Mehmet Ayhan Kuzu MD FACS3, Samet Yalcin MD4, Murat Palabiyikoglu MD5, Necati Ormeci MD1

Cytomegaloviral enterocolitis is an uncommon infection that can complicate inflammatory bowel disease. A case of a patient with a three-year history of Crohn’s disease is reported. He had been in a stable condition on mesalamine 4 g/day and methylprednisolone 10 mg/day for three years until four weeks before admission. The patient was admitted with complaints of fever, abdominal pain and watery diarrhea. A diagnosis of an exacerbation of Crohn’s disease was established. The radiological examination revealed narrowing of the terminal ileum. Multiple fistulas and abscess-like images were observed. The patient then underwent ileocolic resection and ileostomy. The histopathological examination revealed Crohn’s ileocolitis with superimposed cytomegalovirus infection. In patients with rapidly deteriorating inflammatory bowel disease, cytomegalovirus infection should be kept in mind as one of the differential diagnoses.

Key Words: Crohn’s ileocolitis; Cytomegalovirus; Inflammatory bowel disease

Infection à CMV chez un patient souffrant de la maladie de Crohn

L’entérocolite à cytomégalovirus (CMV) est une infection rare qui peut compliquer la maladie inflammatoire de l’intestin. On fait ici état du cas d’un patient chez qui la maladie de Crohn a été diagnostiquée il y a trois ans. Son état était stationnaire depuis lors, avec 4 g de mésalamine et 10 mg de méthylprednisolone par jour, jusqu’à quatre semaines avant son admission. Le patient s’est présenté avec des symptômes de fièvre, douleur abdominale et diarrhée liquide. Un diagnostic d’exacerbation de la maladie de Crohn a été posé. L’examen radiologique a révélé un rétrécissement de l’iléon terminal et la présence de nombreuses fistules et pseudo-absces. Le patient a subi une résection iléocolique et une iléostomie. L’examen histopathologique a révélé une entérocolite de Crohn compliquée d’une infection à CMV. Chez les patients dont la maladie inflammatoire de l’intestin s’aggrave subitement, il faut envisager la possibilité d’une infection à CMV parmi les diagnostics différentiels.

CASE PRESENTATION

A 50-year-old man was admitted to the gastroenterology clinic at the Ankara University Medical School in Turkey with complaints of fever, abdominal pain and watery diarrhea. The history revealed Crohn’s disease that had been first diagnosed three years before. He had been in a stable condition on mesalamine (4g/day) and low-dose steroids (10mg/day) for three years until four weeks before admission. On admission, the patient appeared to be chronically ill. His vital findings were as follows: blood pressure 120/70 mmHg; pulse 90 beats/min; temperature 38°C; and respiration rate 18 breaths/min. The physical examination revealed tenderness of the right lower quadrant and concomitantly palpable retroperitoneal lymph nodes. The laboratory findings were sedimentation rate 90 mm/h; C-reactive protein 291 mg/L; white blood cell 16,200/mm³; hemoglobin 112 g/L; platelets 457,000/mm³; prothrombin time 13.3 s; partial thromboplastin time 28.3 s; glucose 6.9 mmol/L; blood urea nitrogen 6.42 mg/dL; creatinine 106 mg/dL; calcium 9 mg/dL; sodium 135 meq/L; potassium 3.8 meq/L; aspartate aminotransferase 0.45 U/L; alanine aminotransferase 0.40 U/L; total protein 40.1 g/dL; albumin 19 g/dL; total bilirubin 30.8 mg/dL; and direct bilirubin 12 mg/dL. Immune markers including...
antinuclear antibodies, antimitochondrial antibodies, anti-smooth muscle antibodies and antineutrophil cytoplasmic antibodies were all negative. The patient was diagnosed with an exacerbation of Crohn’s disease, and an elemental diet, mesalamine therapy at a daily dose of 4 g and prednisolone therapy at a daily dose of 60 mg were started.

The radiological examination of the small intestine demonstrated narrowing of the terminal ileum and thickening on the wall of the small bowel. Multiple fistula and abscess-like images were also observed. On abdominal ultrasonography, there was thickening on the wall of terminal ileum. Abdominal computed tomography revealed an abscess of 1.5 cm in diameter in the mesentery in the umbilical region and adjacent small intestine, and a second small abscess was observed in the subhepatic region (Figure 1). Exploration revealed an inflammatory mass affecting 50 cm of the terminal ileum and the right colon up to the transverse colon. Interloop abscess and enteroenteric fistula formation was detected. Because of the dense adhesion and inflammation, ‘en bloc’ resection of this inflammatory mass was performed (Figure 2). End ileostomy was performed and the distal transverse colon was oversewn. After the operation, the patient gradually improved. Gross examination of the surgical specimen revealed linear ulcers throughout the small intestine and the colon. There were segmental strictures, peri-ileal abscesses and enteroenteric fistula formation in the ileal loops where the bowel wall was thickened.

Microscopically, there were fissuring ulcers and lymphoid aggregates within the bowel walls of both bowel segments. Inflammatory infiltrate extended throughout the thickness of the wall. No granulomas were observed. There were numerous large nuclei at the base of the ulcers and within the surrounding mucosal areas where there was extensive pyloric metaplasia. These cytopathic changes were largely confined to the endothelial cells, which stained positively with CD31. The immunohistochemical examination clearly indicated that these nuclei were strongly positive with anti-CMV antibody (Figure 3). A diagnosis of Crohn’s ileocolitis with superimposed CMV infection was established in light of these findings.

Six months following the first operation, the patient underwent another surgery for bowel continuity. Postoperative follow-up was uneventful at one year.

**DISCUSSION**

CMV is a common virus which infects approximately two-thirds of the general population. CMV has been reported to act on the intestine as a nonpathogenic bystander (4). The majority of infections are not clinically obvious, but CMV may cause clinically significant disease throughout the gastrointestinal tract (9). CMV enterocolitis in adult patients is usually caused by reactivation of the latent virus in an immunocompromised state, such as AIDS patients, transplant...
Cytomegaloviral enterocolitis

of the ileum and a squamous cell carcinoma of the tongue, although the patient was not immunocompromised. In another study (17), CMV infection was detected in a patient with Crohn's disease presenting with severe ileal bleeding. Vega et al (4) studied nine steroid-resistant IBD patients and found CMV infection in one of the two Crohn's disease patients with both colon and ileum involvement after the operation. The histopathological examination of our patient's specimen revealed CMV inclusion bodies in both the ileum and colon.

CONCLUSION

IBD patients with severe colitis not responding to treatment should be studied for CMV infection, particularly when the clinical course has deteriorated because of immunosuppression. In Crohn's disease, CMV infection is relatively rare compared with ulcerative colitis. In our patient, the underlying cause for the clinical deterioration and requirement for immediate surgical intervention seems to be CMV infection. CMV infection was detected postoperatively in the patient. If the infection had been detected preoperatively, the patient could have been treated without a need for surgical intervention. Therefore, it can be concluded that early detection and treatment of CMV infection may alter the course of the disease.

recipients or corticosteroid treatment (2). In addition, CMV infection may play a role in the natural history of IBD (10), increasing the risk of exacerbations (4), severe complications and refractory pouchitis in the patients with proctocolectomies and ileoanal reservoirs (11). However, there are some reports suggesting that CMV infection affects the clinical course of IBD. Cases of patients with self-limited colitis and colonic ulcers associated with CMV have been reported (6,12). An association between CMV infection and the onset of IBD has also been presented (13,14). In the present case, CMV serological markers of the patient were not studied preoperatively. However, the patient's clinical condition deteriorated while he was in remission with low-dose steroid therapy, which suggested that Crohn's disease may have preceded CMV infection or developed concomitantly.

A study by Cottone et al (15) in which 62 cases of patients with severe colitis were studied, seven of 19 (37%) steroid-resistant patients had CMV infection. Two of these patients also had a history of Crohn's disease. After surgery, CMV infection was detected in the surgical specimen of one patient. In this study, the patients with CMV colitis had a history of steroid use longer than three months (15). Similarly, the surgical specimen of our case revealed CMV infection, and the patient had a history of low-dose steroid use for longer than three months.

CMV infection of the ileum has rarely been reported. One of these reports (16) involved a patient with CMV infection
