Nonlinear evolution equations widely describe phenomena in various fields of science, such as plasma, nuclear physics, chemical reactions, optics, shallow water waves, fluid dynamics, signal processing, and image processing. In the present work, the derivation and analysis of Lie symmetries are presented for the time-fractional Benjamin–Bona–Mahony equation (FBBM) with the Riemann–Liouville derivatives. The time FBBM equation is reduced to a nonlinear fractional ordinary differential equation (NLFODE) using its Lie symmetries. These symmetries are derivations using the prolongation theorem. Applying the subequation method, we then use the integrating factor property to solve the NLFODE to obtain a few travelling wave solutions to the time FBBM.

1. Introduction

Partial differential equations running into the thinking of most of the researchers as it represented the importance in several topics of scientific fields as mechanics, optical fibers, medical sciences (as breast cancer), biological science, turbulent bursts, and oceans waves [1–11].

The differential model has a broad application in many phenomena as in [12–14]. Recently, nonlinear fractional differential equations (NLFDEs) show significantly in engineering and applications of other sciences, for example, electrochemistry, physics, electromagnetics, and signal data processing [15–22].

Getting exact solutions for these forms of equations became an important issue; thus, most researchers try to achieve this target. The most effective method for obtaining exact solutions for NLFDEs is the Lie symmetry reduction method. There are many papers for using Lie’s method to obtain explicit solutions for NLFDEs [23–26].

In our paper, we drive the symmetry vectors for the time FBBM equation and present new closed-form solutions for it. The FBBM equation has many forms [27–30], and we choose to work on the following form:

\[ D_\alpha^t \psi = -\psi_x - \psi \psi_x + \psi_{xxt}, \]

where \( \psi_{xxt} \) is the dissipative term.

The manuscript is prearranged as follows. In Section 2, Lie’s group method for FPDEs is exposed. In Section 3, we apply the Lie group reduction method to obtain Lie point symmetry for the time FBBM equation (1). At the end of Section 4, we use these similarity variables to get the reduced equation. In Section 4, we use two methods for solving the resulting ordinary differential equation, the first method is the subequation method and the second method is the integrating factors method to get new solutions that have the properties and form the travelling wave form for the FBBME. In the end, conclusions are written in Section 5.

2. Notations and Introductory

2.1. Fractional Riemann–Liouville Derivative. In this section, we show some definitions for RL fractional derivative [31], which can be considered as follows:
\[ D^n_t f = \begin{cases} \frac{d^n f(t)}{dt^n}, & \text{if } n = \alpha, n \in \mathbb{N}, \\ \frac{d^{n-1} f(t)}{dt^{n-1}}, & \text{if } 0 \leq n - 1 < n, n \in \mathbb{N}, \end{cases} \quad (2) \]

where \( D^n_t \) is the total differentiation of integer number of orders \( \alpha, (\alpha > 0) \), the Gamma function is \( \Gamma(n-\alpha) \), and \( I^{\alpha} f(t) \) is the (RL) fractional integral of an order of \( \alpha \).

\[ I^{\alpha} f(t) = \frac{1}{\Gamma(n-\alpha)} \int_0^t (t-s)^{n-\alpha-1} f(s) ds, \quad n > 0, \quad \alpha > 0. \quad (3) \]

where \( D^n_t \) is the total differentiation of integer number of orders \( \alpha, (\alpha > 0) \), the Gamma function is \( \Gamma(n-\alpha) \), and \( I^{\alpha} f(t) \) is the (RL) fractional integral of an order of \( \alpha \).

\[ \frac{\partial^\alpha f}{\partial t^\alpha} = \frac{1}{\Gamma(n-\alpha)} \int_0^t (t-s)^{n-\alpha-1} f(s) ds, \quad 0 \leq n - 1 < n. \quad (4) \]

2.2. Notations for Lie Symmetry Reduction Method for the Time FPDEs. In this section, we show in detail the main notations and definitions that will be used for obtaining the symmetries of NLFPDEs.

Here, we will consider timing NLFPDEs of the form [31–33]

\[ \frac{\partial^n\psi}{\partial t^n} = F(t, x, \psi, \psi_x, \psi_{xx}), \quad (0 < \alpha \leq 1). \quad (5) \]

Assume, equation (2) has a Lie vector \( X \) in the form

\[ X = \xi^1(x, t, u) \frac{\partial}{\partial x} + \xi^2(x, t, u) \frac{\partial}{\partial t} + \eta(x, t, u) \frac{\partial}{\partial u}. \quad (6) \]

**Theorem 1.** Equation (1) concedes a one-parameter group of infinitesimal transformations in equation (2) with the Lie Vector \( X \) if and just if the accompanying infinitesimal conditions hold:

\[ \Pr^{(a_3)} X(\Delta)|_{\Delta=0} = 0, \quad (10) \]

where \( \Delta = D^n_t u - F(t, x, u, u_x, u_{xx}, \ldots) \) and \( \Pr \) is the 3rd prolongation of the infinitesimal generator \( X \).

**Definition 2.** Prolonged vector is given by [31]

\[ \xi^k(t, x, u, \psi)|_{t=0} = 0. \quad (12) \]

The athextended infinitesimal, which deals with fractional derivatives, has the following form [36–38]:

\[ t = t + \varepsilon \xi^2(t, x, u) + O(\varepsilon^2), \]

\[ x = x + \varepsilon \xi^1(t, x, u) + O(\varepsilon^2), \]

\[ \psi = \psi + \varepsilon \eta(t, x, u) + O(\varepsilon^2), \]

\[ \frac{\partial^\alpha \psi}{\partial t^\alpha} = \frac{\partial^\alpha \psi}{\partial s^\alpha} + \varepsilon \eta^x(t, x, u) + O(\varepsilon^2), \]

\[ \frac{\partial^\alpha \psi}{\partial \xi^\alpha} = \frac{\partial^\alpha \psi}{\partial \xi^\alpha} + \varepsilon \eta^x(t, x, u) + O(\varepsilon^2), \]
\[ \eta^0_n = \frac{\partial^k H}{\partial t^k} \eta_u + (\eta_u - \alpha D_t (\xi^0)) \frac{\partial^k u}{\partial t^k} + \mu - \sum_{n=1}^\infty \left( \left( \frac{\alpha}{n} \right) D_t^0 (\xi^0) D_t^{\alpha-n} (\xi^0) + \sum_{m=1}^\infty \left( \left( \frac{\alpha}{m} \right) \frac{\partial^m \eta_u}{\partial t^m} - \left( \left( \frac{\alpha}{n+1} \right) D_t^{\alpha+1} (\xi^0) \right) D_t^{\alpha-n} (\xi^0) \right) \right), \]  

where

\[ \mu = \sum_{n=2}^\infty \sum_{m=2}^\infty \sum_{k=2}^\infty \left( \frac{\alpha}{n} \right) \frac{\partial^m}{\partial t^m} \left( u^k \right) \frac{1}{k!} \left( \frac{\eta}{n-\alpha} \right). \]  

(14)

Remember that

\[ \left( \frac{\alpha}{n} \right) = \frac{(-1)^{n-1} \alpha!}{(n-\alpha) \Gamma (n-\alpha) \Gamma (n+1)}. \]  

(15)

Due to linearization of the infinitesimal \( \eta \) in \( u \) and the presence of \( \partial^k \eta / \partial u^k \), \( \mu \) will vanish, where \( k \geq 2 \) in equation (14).

Lemma 1. The function \( \psi = \theta (x, t) \) can be defined as an invariant solution of (2) if and only if

(i) \( \psi = \theta (x, t) \) is an invariant surface of equation (2)

(ii) \( \xi^2 (x, t, \theta) \partial_t + \xi^1 (x, t, \theta) \partial_x = \eta (x, t, \theta) \)

3. Lie Symmetry and Reduction of FBBM Equation

In this partition, the Lie symmetry reduction method was applied to find the similarity variables for a one-dimensional time (FBBM) equation. Suppose that (1) is an invariant under (2); we have that

\[ \psi_t + \psi \psi_x + \psi_x - \psi_x t = 0. \]  

(16)

Thus, \( \psi (x, t) \) satisfies equation (1). Applying the third prolongation to (1), we have the accompanying deciding condition, which is given as

\[ \eta^0_n + \psi \eta + (\psi + 1) \eta^2 - \eta^x t = 0. \]  

(17)

Substituting (7) and (8) into (16) and equaling coefficients in derivatives for \( x \) and power of \( u \) to zero, the system of equations is obtained:

\[ \left( \frac{\alpha}{n} \right) \partial^m \eta_u - \left( \frac{\alpha}{n+1} \right) D_t^{\alpha-n} (\xi^0) = 0, \quad n = 1, 2, 3, \ldots, \]

\[ \xi^2 = \xi^1 = \xi_0 = \eta_{x^2} = 0, \quad (1 - \alpha) \xi^2 + 2 \xi^1 = 0, \]

\[ \psi \eta_x - \eta_{x^2} + \partial_t^0 \eta - \psi \partial_t^0 \psi + \eta_x = 0, \quad 2 \xi_{x^2} - \eta_{x^2} = 0. \]

(18)

By solving the obtained equations in (18), we get the following infinitesimal:

\[ \xi^1 = c_1 + (\alpha - 1)c_2 x, \]

\[ \xi^2 = 2c_2 t, \quad \eta = -(\alpha + 1)c_2 (\psi + 1), \]

where \( c_1 \) and \( c_2 \) are constants. By the previous infinitesimal, equation (1) has two vector fields in the form

\[ X_1 = \frac{\partial}{\partial x}, \quad (20a) \]

\[ X_2 = (\alpha - 1)x \frac{\partial}{\partial x} + 2t \frac{\partial}{\partial t} - (\alpha + 1)(\psi + 1) \frac{\partial}{\partial \psi}. \]  

(20b)

Case 1. For the infinitesimal generator in (20a), we have a characteristic equation in the following form:

\[ \frac{dx}{1} = \frac{dt}{0} = \frac{d\psi}{0}. \]  

(21)

By solving the previous equation, we get the variables \( t \) and \( \psi \). Putting \( \psi = f (t) \) into (1), we obtain the following fractional ODE:

\[ D_t^0 f (t) = 0. \]  

(22)

By solving the above equation, we obtain

\[ \psi = a_1 t^{\alpha-1}, \]  

(23)

where \( a_1 \) is constant of integration.

Case 2. For \( X_2 \) in equation (20b), the similarity variables for the infinitesimal generator \( X_2 \) can be obtained from the equation:

\[ \frac{dx}{(\alpha - 1)x} = \frac{dt}{2t} = \frac{d\psi}{(\alpha + 1)(\psi + 1)}. \]  

(24)

The previous equation is called the characteristic equation; by solving it, we have the similarity variable as a result in the form:

\[ \xi = x t^{-((\alpha - 1)/2)}. \]  

(25)

The group invariant solution

\[ \psi (x, t) = t^{-((\alpha + 1)/2)} f (\xi) - 1 = g (\xi) - 1, \]  

(26)

where \( f (\xi) \) is a new arbitrary function of \( \xi \) and \( g (\xi) = t^{-((\alpha + 1)/2)} f (\xi) \). By using equation (26), equation (1) is transformed into FODE.

Theorem 3. The transformation in (25) and (26), which is obtained from the similarity group method, reduces equation (1) to NLFODE as below:
Using the operator EK fractional differential operator
[32, 34],
\[
\left( P_{\beta}^{\alpha} f \right)(\xi) = \sum_{j=0}^{n-1} \left( \frac{\xi^2 + j - 1}{\beta} \right) \left( K_{\beta}^{\alpha+n-1}(f) \right)(\xi),
\]
\[
n = \left\{ \begin{array}{ll}
[a] + 1, & a \neq N, \\
[a], & a \in N,
\end{array} \right.
\]
where
\[
\left( K_{\beta}^{\alpha} f \right)(\xi) = \left( \frac{1}{\Gamma(a)} \right)^{\infty} \int_0^\xi (\psi - 1)^{a-1} \psi^{-(\xi + \beta)} f(\xi)^b d\psi, \quad \alpha > 0,
\]
\[
f(\xi), \quad \alpha = 0.
\]

\section*{Complexity}

4.1. Clarifications for the Subequation Method. The subequation method [39] is presented in this section. Consider the NLPDE in the form

\[
\frac{\partial^n}{\partial t^n} \left[ t^{n-(3\alpha+1)/2} \left( K_{2/(a-1)}^{1-a/2n}(f) \right) (\xi) \right] = \frac{\partial^{n-1}}{\partial t^{n-1}} \left[ \frac{\partial}{\partial t} \left[ t^{n-(3\alpha+1)/2} \left( K_{2/(a-1)}^{1-a/2n}(f) \right) (\xi) \right] \right]
\]

Repeating \( n - 1 \) times, we have

\[
\frac{\partial^n}{\partial t^n} \left[ t^{n-(3\alpha+1)/2} \left( K_{2/(a-1)}^{1-a/2n}(f) \right) (\xi) \right] = \frac{\partial^{n-1}}{\partial t^{n-1}} \left[ \frac{\partial}{\partial t} \left[ t^{n-(3\alpha+1)/2} \left( K_{2/(a-1)}^{1-a/2n}(f) \right) (\xi) \right] \right]
\]

Using the definition of EK fractional differential operator in (28) to rewrite (35), we obtain

\[
D_t^\alpha g(\xi) = \frac{\partial^n}{\partial t^n} \left[ t^{n-(3\alpha+1)/2} \left( K_{2/(a-1)}^{1-a/2n}(f) \right) (\xi) \right].
\]

\section*{Remark 1.}
The fractional derivative must achieve the linearization property [37, 39]:

\[
D_t^\alpha (h(t) + k(t)) = D_t^\alpha h(t) + D_t^\alpha k(t),
\]

\[
D_t^\alpha t^\gamma = \frac{\Gamma(\gamma + 1)t^{\gamma-a}}{\Gamma(\gamma - \alpha + 1)}, \quad \gamma > \alpha - 1.
\]

Using the invariant group solution in (26), (37), and (38), we obtain

\[
D_t^\alpha \psi(x, t) = D_t^\alpha g(\xi) - D_t^\alpha (1).
\]

Hence,

\[
D_t^\alpha \psi(x, t) = t^{n-(3\alpha+1)/2} \left( P_{2/(a-1)}^{1-a/2n}(f) \right)(\xi) - \frac{\Gamma^n}{\Gamma(1-a)}
\]

Thus, (1) can be reduced to

\[
\left( P_{2/(a-1)}^{(1-3\alpha)/2n}(f) \right)(\xi) = \frac{t^{1-a/2}}{\Gamma(1-a)} + \left( \frac{3}{2} \alpha + \frac{1}{2} \right) f(\xi)
\]

and the theorem is totally proofed.

4. Explicit Solutions for FBBM Equation
\[ P(\psi, \psi_t, \psi_x, D_\xi^\alpha \psi, D_x^\alpha \psi, \ldots), \quad (0 < \alpha \leq 1), \]  
(42)

where \( \psi \) is a dependent variable, \( P \) is a series of \( \psi \) and its fractional derivatives, and \( D_\xi^\alpha \psi \) and \( D_x^\alpha \psi \) are the Riemann–Liouville (RL) derivatives of \( \psi \) w.r.t \( t \) and \( x \). Here, we present the principles for the subequation technique. By using the d’Alembert transformation,

\[ \psi(x, t) = \psi(\zeta), \quad \zeta = x + ct, \]  
(43)

where \( c \) is constant that will be determined later, and we can rewrite (41) as NLFODE:

\[ P(\psi, \psi_t, \psi_x, c^\alpha D_\xi^\alpha \psi, D_x^\alpha \psi, \ldots), \quad (0 < \alpha \leq 1). \]  
(44)

According to the subequation procedure, assume that the wave solution will be written in the following form:

\[ \psi(\zeta) = a_0 + \sum_{i=1}^{n} a_i \phi(\zeta)^i, \]  
(45)

where \( a_i \), \( i = 1, \ldots, n \) are constants, which will be determined later, \( n \) belongs to integers numbers, which are determined by equaling the highest order derivatives and nonlinear terms in (44) together, and the function \( \phi(\zeta) \) achieves the Riccati equation of fractional order

\[ D_\xi^\alpha \phi(\zeta) = \sigma + \phi(\zeta)^2, \]  
(46)

where \( \sigma \) is a constant. Some trigonometric solutions of the fractional Riccati equation (46) are

\[ \phi(\zeta) = \begin{cases} 
-\sqrt{-\sigma} \tan h_\alpha(\sqrt{-\sigma} \zeta), & \sigma < 0, \\
-\sqrt{-\sigma} \cot h_\alpha(\sqrt{-\sigma} \zeta), & \sigma < 0, \\
\sqrt{\sigma} \tan h_\alpha(\sqrt{\sigma} \zeta), & \sigma > 0, \\
-\sqrt{\sigma} \cot h_\alpha(\sqrt{\sigma} \zeta), & \sigma > 0, \\
-\Gamma(1 + \alpha) \zeta^{\omega} + w, & \text{w = constant, } \sigma = 0.
\end{cases} \]  
(47)

By substituting forms (45) into (44) and setting the coefficients of \( \phi(\zeta) \) to be zero, we obtain an algebraic system in \( a_i \), \( i = 1, \ldots, n \) and \( c \). By solving the determine system, we obtain the constants \( a_i \), \( i = 1, \ldots, n \) and \( c \). Substituting these constants and the solutions of (47) into (45), we obtain the closed form solutions of (42).

4.2. Applying the Subequation Method to the Time FBBM Equation. We now implement a subequation method to (1). We will use the transformation

\[ \psi(x, t) = \psi(\zeta), \quad \zeta = x + ct, \]  
(48)

where \( c \) is a constant, and this will transform (1) into an NLFODE:

\[ c^\alpha D_\xi^\alpha \psi = -\psi_x - \psi \psi_x + c \psi_x. \]  
(49)

We now assume that (49) has the solution in the form

\[ \psi(\zeta) = a_0 + \sum_{i=1}^{n} a_i \phi(\zeta)^i, \]  
(50)

where \( a_i \), \( i = 1, \ldots, n \) are constants, which will be determined, and \( \phi(\zeta) \) achieves equation (46).

Balancing the highest order derivative terms with nonlinear terms in equation (49), we obtain \( n = 2 \). Hence,

\[ \psi(\zeta) = a_0 + a_1 \phi(\zeta) + a_2 \phi(\zeta)^2. \]  
(51)

We then substitute (51) along with (46) into (49), then collect the coefficients of \( \phi(\zeta) \), and set them to equal zero. A set of algebraic equations are obtained in knowns \( c \), \( a_0 \), \( a_1 \), and \( a_2 \). Solving these algebraic equations with the help of the software program (Maple), we get the following values.

Thus, from (47), we obtain five forms of explicit travelling wave solutions of (1), namely:

\[ c = \frac{1}{12} \sigma, \]  
\[ \sigma = \sigma, \]  
\[ a_0 = -c^\sigma - 1 + \frac{2}{3} \sigma^2, \]  
\[ a_1 = 0, \]  
\[ a_2 = \sigma. \]  
(52)

Thus, from (47), we obtain five forms of explicit travelling wave solutions of (1), namely:

\[ \psi_1(x, t) = a_0 + \sigma(-\sqrt{-\sigma} \tan h_{\alpha}(\sqrt{-\sigma}(x + ct)))^2, \quad \sigma < 0, \]  
(53)

\[ \psi_2(x, t) = a_0 + \sigma(-\sqrt{-\sigma} \cot h_{\alpha}(\sqrt{-\sigma}(x + ct)))^2, \quad \sigma < 0, \]  
(54)

\[ \psi_3(x, t) = a_0 + \sigma(\sqrt{\sigma} \tan h_{\alpha}(\sqrt{\sigma}(x + ct)))^2, \quad \sigma > 0, \]  
(55)

\[ \psi_4(x, t) = a_0 + \sigma(-\sqrt{\sigma} \cot h_{\alpha}(\sqrt{\sigma}(x + ct)))^2, \quad \sigma > 0, \]  
(56)

\[ \psi_5(x, t) = a_0 + \sigma\left(-\Gamma(1 + \alpha)(x + ct)^\omega + w\right)^2, \quad \sigma = 0, \]  
(57)

where \( a_0 \) is arbitrary constant. We plot the result in equation (57) in the three dimensions, contour plot, and density plot, as shown in Figures 1–3, respectively.

4.3. Applying Simple Transformation. We solve the conformable FBBM equation using simple transformation to change the fraction order in partial derivative to nonsolvable ODE. For the reduction of (1) to ODE, we use the following transformation:
\[ \psi(x,t) = \psi(\zeta), \quad \text{where } \zeta = vx - k \frac{t}{\alpha} \quad (58) \]

where \( v \) and \( k \) are arbitrary constants; we can rewrite (1) as NLODE:

\[ kv^2 \psi_{\zeta\zeta\zeta} = (k - v) \psi_\zeta - v \psi \psi_\zeta. \quad (59) \]

This equation has no implicit solution but possesses two integrating factors. We apply the integrating factor technique to obtain an analytical solution for (59).

Equation (59) has two integrating factors (IF) as follows:

\[ \mu_1 = \psi(\zeta), \]
\[ \mu_2 = 1. \quad (60) \]

Using these integrating factors by the same steps in [39] and neglecting the constants of integration, equation (59) will be reduced to

\[ 3kv^2 \left( \psi_\zeta \right)^2 = 3(k - v) \psi^2 - v \psi^3. \quad (61) \]

By solving this equation, we obtain travelling wave solution for (1):

\[ \psi(\zeta) = \frac{1}{v} \left( 3 \left( -v \tan \left( \frac{1}{2} \frac{\sqrt{-k^2 + kv} (\zeta + c)}{kv} \right) \right)^2 + k - v + k \tan \left( \frac{1}{2} \frac{\sqrt{-k^2 + kv} (\zeta + c)}{kv} \right)^2 \right). \quad (62) \]
Replacing $\zeta = vx - k (t^\alpha/\alpha)$, 

$$
\psi(x,t) = \frac{1}{\nu} \left[ 3 \left( -v \tan \left( \frac{1}{2} \sqrt{-k^2 + kv (vx + k (t^\alpha/\alpha) + c)} \right) \right) + k - v + k \tan \left( \frac{1}{2} \sqrt{-k^2 + kv (vx + k (t^\alpha/\alpha) + c)} \right) \right]^2 .
$$

Equation (64) has closed form solution, but, in the back substitution step, we are unable to get $\psi(x,t)$ even if we neglect the values of constants. So, from here, we can say the integrating factor method for reducing and solve ODEs, occasionally, more effectiveness than the Lie reduction method. Result obtained in (63) is plotted in Figure 4 at different values of $\alpha$. We observe that, by decreasing the value of $\alpha$, the top of the wave has a parabolic shape.

Comparing our result in (63) with results in [5], specially equation (17), we find that the two solutions are travelling wave solutions, but the amplitude and direction of flow are different.

5. Conclusions

In this paper, we show the importance and the effective of the Lie symmetry reduction method on the FBBM equations. We obtain time FBBM equation’s Lie symmetry generators and then reduce the equation to FODE using these symmetry vectors. The projected analysis is extremely effective and dependable for getting similarity solutions for fractional differential equations. New travelling solutions were derived for the FBBM equation using the subequation method.
