1. Introduction

*Herbaspirillum seropedicae* are Gram-negative oxidase-positive nonfermenting rods of Betaproteobacteria class, commonly found in the rhizosphere. More recently, some *Herbaspirillum* species have transitioned from environment to human hosts, mostly as opportunistic (pathogenic) bacteria. We present a 58-year-old female with non-small-cell lung cancer (NSCLC) who presented with pneumonia and was found to have *Herbaspirillum seropedicae* bacteremia.

1.1. Case History.

A 58-year-old woman with NSCLC on Pralsetinib presented with fevers and rigors for 2 days. Coarse breath sounds were auscultated on the right upper lung field. Labs revealed leukopenia and mild neutropenia. CT chest revealed right upper lobe pneumonia. She was admitted for sepsis secondary to pneumonia and placed on broad spectrum antibiotics with intravenous piperacillin-tazobactam and vancomycin. The patient continued to have fever 2 days after admission (max: 102.8°F). Preliminary blood cultures grew Gram-negative rods. The patient continued to have temperature spikes on the 3rd day of antibiotics (T_{max} 101.5°F). Blood cultures revealed oxidase-positive nonfermenting rods. The patient’s antibiotic was changed to IV meropenem on the 4th day of hospitalization. Ultimately, on the seventh day of hospitalization, the blood culture was confirmed from outside lab as *Herbaspirillum seropedicae*. The patient started feeling better and defervesced after about 24 hours. Discussion. More recently, *Herbaspirillum spp* have been recovered from humans. Our patient had *Herbaspirillum* bacteremia, and reported regularly cleaning her pond and weeding her garden with possible exposure to this environmental proteobacterium. *Herbaspirillum* may be more prevalent than earlier thought owing to misidentification. With the institution of appropriate antimicrobial therapy, the outcomes seem mostly favorable.
<1.00) mg/dl, and an elevated creatinine level of 1.56 mg/dl (baseline creatinine of 1 mg/dl). CT chest revealed right upper lobe pneumonia, scattered small pulmonary nodules consistent with metastatic disease, and stable bony metastatic disease of the anterior left 6th rib. She was admitted for sepsis secondary to pneumonia and placed on broad spectrum antibiotics with intravenous piperacillin-tazobactam and vancomycin. She received 2 units of packed red cell transfusion with stable hemoglobin thereafter. Urine analysis was unremarkable. Urine legionella and streptococcus pneumoniae antigens were negative. The patient continued to have fever 2 days after admission (max: 102.8 F). Preliminary blood cultures done at our hospital at Day 2 of hospitalization revealed Gram-negative rods. CT abdomen and pelvis revealed small volume of ascites and jejunal wall thickening with mild adjacent mesenteric edema, suggestive of enteritis. CT chest revealed persistent right upper lobe pneumonia. The patient continued to have temperature spikes on the 3rd day of antibiotics ($T_{\text{max}}$ 101.5 F). Blood cultures revealed oxidase-positive nonfermenting rods. The organism was not clearly identified in our lab, and the specimen was sent to Central Pennsylvania Alliance Laboratory for identification by DNA sequencing using MALDI (matrix-assisted laser desorption/ionization) technique. The patient’s antibiotic was changed to IV meropenem on the 4th day of hospitalization. Port was removed and catheter tip culture was sent, which came out to be negative. Ultimately, on the seventh day of hospitalization, the blood culture was identified from outside lab as Herbaspirillum seropedicae (which was susceptible to all tested antibiotics including amikacin, cepfime, ceftazidime, ciprofloxacin, aztreonam, levofloxacin, meropenem, piperacillin/tazobactam, and ticarcillin/clavulanate). The patient started feeling better and defervesced after about 24 hours of being on meropenem. The patient was discharged with a midline catheter to continue IV meropenem for a total of 14 days and follow-up for outpatient monitoring. The WBC count at discharge was 5.1 x $10^3$ µ/L, ANC was 3978 cells/µl, and CRP was 6.36 mg/dl. On further questioning to assess for risk factors, the patient reported taking care of her pond and regularly cleaning weeds.

2. Discussion

The first described species of the genus Herbaspirillum was the bacterium Herbaspirillum seropedicae, which was found colonizing the roots and aerial parts of important crops [1]. More recently, Herbaspirillum spp. have been recovered from the blood and sputum/bronchoalveolar lavage of patients with cystic fibrosis and pneumonia [4, 6, 11] and from blood in patients with leukemia [6, 7, 12], aplastic anemia [7], multiple myeloma [13], and cellulitis [8]. Our patient is a 58-year-old woman with NSCLC on RET-inhibitor pralsetinib who presented with right upper lobe pneumonia and had blood culture positive for oxidase-positive nonfermenting Gram-negative rod, which was confirmed as Herbaspirillum only on Day 7 of hospitalization by which time the patient was already improving with meropenem therapy. On retrospect, our patient had been regularly cleaning her pond and weeding her garden with possible exposure to this environmental proteobacterium, supporting this change in dynamics from environmental bacterium to opportunistic pathogen. However, it is not entirely clear why the patient only defervesced and improved after 24 hours of switching piperacillin/tazobactam to meropenem, even though her culture report suggested sensitivity to piperacillin/tazobactam. New genomic data findings suggest that the transition from environmental to pathogenic led to the loss and acquisition of specific genes to allow colonization and survival in new environments. The strains that have been infectious to humans have lost the genes for nitrogen fixation and acquired genes for lipopolysaccharide biosynthesis with the addition of sialic acids to evade the immune system [1].

We reviewed the literature for available Herbaspirillum cases and identified 9 published studies from 2005 to 2019 (Table 1), with Herbaspirillum bacteremia, cellulitis or pneumonia. Tan and Oehler reported Herbaspirillum bacteremia and cellulitis in a patient with aquatic exposure [8]. Ziga et al. reported Herbaspirillum bacteremia in a 2-year-old girl with a history of acute lymphoblastic leukemia (ALL) after induction chemotherapy and stem cell transplant [6]. Chen et al. reported Herbaspirillum bacteremia in an ALL patient on chemotherapy after taking sugarcane juice [12]. Regunath et al. described a case of bacteremia caused by gentamicin-resistant Herbaspirillum in an immunocompetent adult male farmer [11]. Suwantarat et al. reported the first fatal case-related H. seropedicae bacteremia secondary to pneumonia in an immunocompromised 65-year-old man with end-stage renal disease and multiple myeloma [13]. Abreu-Di Berardino et al. described Herbaspirillum huttiense pneumonia in a patient with essential thrombocytosis [9]. Liu et al. reported Herbaspirillum huttiense bacteremia in an elderly patient with no obvious immune suppression, who later went on to develop a pneumonia, where despite adequate treatment, microbiological eradication was not easily achieved, and septicemia lasted for several days along with sputum culture positivity for Herbaspirillum huttiense 2 months later [10].

Chen et al. investigated a potential cluster of hospital-based Herbaspirillum infections in cancer patients at the University of Texas MD Anderson Cancer Center, initially identified as Burkholderia cepacia complex and subsequently reidentified as Herbaspirillum species by the Cystic Fibrosis Foundation Burkholderia cepacia Research Laboratory and Repository (BcRLR) at the University of Michigan. The authors identified a total of 8 patients with bacteremia and pneumonia with cultures positive for Herbaspirillum species between July 2011 and August 2012 (including 5 clusters and 3 additional cases identified prospectively). 5 of the 8 patients were females and the median age was 53 years (2–67 years) [7].

Spilker et al. reported a 26-year-old male with moderate to severe lung disease with Gram-negative rod bacteremia at hospital day 23. The patient was admitted for methicillin-resistant staphylococcus aureus (MRSA) and Pseudomonas pneumonia, and cultures were initially misidentified as Burkholderia cepacia complex [4]. The authors analyzed

isolates from sputum from over 1,100 cystic fibrosis patients across 8 years (January 2000 to December 2007) and found *Herbaspirillum* in only 28 patients (<3%) with ages ranging from 20 months to 5 years, of which 3 isolates were *Herbaspirillum huttiense*, 3 were *Herbaspirillum frisingense*, 2 were *Herbaspirillum seropedicae*, and 2 were *Herbaspirillum putei*, and the remaining eighteen isolates could not be speciated [4]. Prior to the correct identification of *Herbaspirillum* at the BcRLR for the above 28 specimen, they had been identified as *Burkholderia cepacia* complex in 19 (68%) and *Ralstonia* in 4 (14%). Most patients appeared to have had transient respiratory tract colonization with *Herbaspirillum* except for bacteremia in one patient and a chronic respiratory tract infection in another [4].

Tetz and Tetz, for the first time, identified *Herbaspirillum frisingense* from the bladder of a human patient with urinary tract infection (UTI). Furthermore, genome analysis revealed numerous factors such as adhesins, urease, hemolysin D, and pilin that contribute to the bacterium’s virulence in UTIs. The authors suggested that further research of this *Herbaspirillum* spp would aid in better understanding of its implication in UTI [14]. Similarly, Wu et al. performed a comprehensive analysis of urinary microenvironment of bladder cancer and identified *Herbaspirillum* as one of the species associated with an increased risk of progression, suggesting its potential role in risk stratifying bladder cancer [15].

As evidenced by the above studies, *Herbaspirillum* is an emerging pathogen and may be more prevalent than earlier thought owing to misidentification for organisms like *Burkholderia cepacia* complex due to phylogenetic and phenotypic resemblance [4, 6, 7, 13]. Antimicrobial susceptibilities may serve as a means for differentiating *Herbaspirillum* species from *Burkholderia cepacia* complex because the latter are usually multidrug resistant, whereas *Herbaspirillum* is not. With the institution of appropriate antimicrobial therapy, the outcomes seem mostly favorable and the bacteria appear to be easily eradicated, except in 1 case reported by Liu et al. Misidentification as *Burkholderia* complex can have serious implications for clinical care, and distinction between these is important due to different resistance profiles and different therapeutic implications. The increased availability of newer molecular methods (e.g., MALDI-TOF MS) should allow laboratories to correctly identify this organism and reduce misidentification by established microbial identification systems.
