Case Report
Retained Intraabdominal Gossypiboma, Five Years after Bilateral Orchiopexy

1. Introduction
Gossypiboma is a term used to describe a mass within the body that comprises a cotton matrix surrounded by a foreign body reaction. Overlooking a foreign body can sometimes occur despite extreme caution during surgery. A foreign body can trigger a granulomatous reaction and may result in the formation of a sizeable mass. The word “Gossypiboma” is bilingually derived from Latin “gossypium” (cotton) and Kiswahili “boma” (place of concealment) [1].

2. Case Presentation
The patient is a 24-year-old Iranian infertile male that referred to our clinic for work up of infertility. He was a married gentleman since 4 years. In the past medical history no noticeable point is noted. In the past surgical history, he underwent laparotomy for the bilateral orchiopexy of intraabdominal testes 5 years ago in another center. Vital signs were normal and BMI was 22. Upon physical examination, positive findings were atrophic testes and a scar of pfannenstiel incision. A foreign body reaction, a granulomatous reaction, may result in the formation of a sizeable mass. The word “Gossypiboma” is bilingually derived from Latin “gossypium” (cotton) and Kiswahili “boma” (place of concealment) [1].
and yellow, thick pus released in which a sponge was found (Figures 1, 2, and 3). The operation terminated unevently and the patient was discharged home after 3 days, without any problem.

3. Discussion

Retained postoperative foreign body, of which surgical sponges are the most common, is a rare condition. The incidence of gossypiboma is difficult to calculate. It varies between 1 in 100 and 1 in 5,000 procedures [2, 3], because some patients remain asymptomatic and are never discovered. This condition is often underestimated because case numbers are calculated only on the basis of malpractice claims and because the operations that form the denominator for their calculation include large numbers of procedures that are unlikely to result in retained sponges. Another reason of unreporting of occurrences is due to the fear of medicolegal repercussions. It is difficult to recognize a gossypiboma by using radiological screening if the sponge does not have any radiological marker on itself, because the cotton can simulate hematoma, granulomatous process, abscess formation, cystic masses or neoplasm. Gossypibomas can have atypical calcification and air bubbles as well [4].

Gossypibomas most commonly occur in the abdominal or pelvic cavity, as after gynecologic and upper abdominal surgical procedures [5]. Much of the gossypibomas (75%) are identified only after abdominal or pelvic surgery [4]. Retained surgical sponges can cause serious consequences such as bowel or visceral perforation, obstruction or fistula formation, sepsis or even death [6]. Intraabdominal gossypibomas can migrate into the ileum, stomach, colon or bladder without any apparent opening in the wall of these luminal organs [7]. Retained sponges are more common in obese patients and after emergency surgery [8, 9]. Obese patients have a huge intraperitoneal space to hide sponges, and obesity may increase the technical difficulty of the operation. Gawande et al. reported that retained sponges are 9 times more likely after an emergency operation and 4 times more likely when an unexpected change in the surgical procedure is undertaken [6].

The clinical presentation of gossypiboma is variable and depends on the location of the sponge and the type of reaction.

There are 2 types of foreign body reaction in pathology: an exudates reaction leading to abscess formation like our case or chronic internal or external fistula formation, and an aseptic fibrinous reaction resulting in adhesion, encapsulation, and eventual formation of granuloma. The latter usually presents much later than exudates reaction sequelae. They usually remain asymptomatic or present with pseudotumor syndrome [5]. This inflammatory granulomatous reaction is the most likely cause of the extraosseous accumulation of Tc-99m MDP [10].

Common symptoms and signs of gossypiboma are abdominal distention, ileus, tenesmus, pain, palpable mass, vomiting, weight loss, diarrhea, abscess, and fistula formation [11]. Because the symptoms of gossypiboma are usually nonspecific and may appear years after surgery, the diagnosis of gossypiboma usually comes from imaging studies and a high index of suspicion.

The most impressive imaging finding of gossypiboma is the curved or banded radio-opaque lines on plain radiograph. The ultrasound feature is usually a well-defined mass containing wavy internal echogenic focus with a hypoechoic rim and a strong posterior shadow. However,
this is often misinterpreted due to its clinical rarity [12]. On CT, a gossypiboma may manifest as a cystic lesion with internal spongiform appearance with mottled shadows as bubbles, hyperdense capsule, concentric layering, or mottled shadows as bubbles, hyperdense capsule, or mottled mural calcifications [13]. When no radio-opaque marker is seen on X-ray or CT, the characteristic internal structure of the gauze granuloma is best visualized on magnetic resonance imaging. It may appear as a low-signal-intensity lesion on T2-weighted images with wavy, folded fabric inner structure, striped or spotted appearance [14].

Possible causatives of sponge retention are emergency surgery, unexpected change in the surgical procedure, disorganization, hurried sponge counts, long operations, unstable patient condition, inexperienced staff, inadequate staff numbers, and patient with high body mass index (BMI) [15]. The present patient was not an obese man because his BMI was 22.

Newer technologies are being developed that will hopefully decrease the incidence of retained foreign body, like radiofrequency identification (RFID). In this system, commonly used surgical gauze sponges, which have been tagged with a radiofrequency identification (RFID) chip scanned with a barcode scanner [16]. The overall objective of this system would be to eliminate errors in the sponge count by removing the human error factor. Furthermore, the sponge count protocol itself has been implicated as a hazard to patient safety [17].

4. Conclusion

Gossypibomas are uncommon, mostly asymptomatic, and hard to diagnose. Particularly chronic cases do not show specific clinical and radiological signs for differential diagnosis. Textiloma should be included in the differential diagnosis of soft-tissue masses detected in patients with a history of a prior operation. Patient-physician and physician-radiologist interactions and compliance enhance the possibility of accurate diagnosis.

Consent

Written informed consent was obtained from the patient for publication of this case report and accompanying images. A copy of the written consent is available for review by the Editor-in-Chief of this journal.
