1.Introduction

Lupus erythematosus is a chronic inflammatory autoimmune disease which encompasses a wide range of clinical manifestations affecting multiple organ systems. There are four main types of lupus: neonatal lupus, discoid lupus, drug-induced lupus, and systemic lupus erythematosus [1]. The modified Gilliam grouping system is a modified classification for cutaneous lupus erythematosus which comprises acute cutaneous lupus erythematosus (ACLE), subacute cutaneous lupus erythematosus (SCLE), and chronic cutaneous lupus erythematosus (CLE) [2].

Clinically, each type of cutaneous lupus presents with some specific features. For instance, discoid lupus presents with thick, firm, erythematous, scaly, and well-demarcated plaques that have the potential to heal with scarring, alopecia, and hypopigmentation [3].

The presentation of eyelid edema is extremely rare; the reported incidence is 0.1% as for the presenting manifestation of systemic lupus erythematosus with an overall incidence of 4.8% [4]. Diagnosis for these cases is essential to prevent scarring, and long-term follow-up is needed as 5% of the population has the risk of developing systemic lupus erythematosus.

In general, the key characteristic that unites cutaneous lupus erythematosus is the histopathology presentations of the following features: hyperkeratosis, epidermal atrophy, vacuolar interface dermatitis, perivascular, and perifollicular mononuclear cell inflammatory infiltrate, with or without the presence of civatte bodies and follicular plugging [5].

2. Case Presentation

A 32-year-old African female presented to the emergency department complaining of persisted periorbital swelling, joint pain, and fever. The periorbital swelling was initially noticed 3 months before her presentation with mild pruritus and no visual disturbance. In addition, she was having intermittent joint pain involving the wrists, fingers, and shoulders. The fever was subjective and not documented with any history of sweating.

On presentation, she also complained of a two-week history of sore throat and difficulty in breathing. Paracetamol was the only medicine the patient was taking to manage her symptoms. She denied using any new medication or product and denied any previous history of allergies.
On her arrival, her vitals were normal and stable. Clinical examination revealed bilateral erythematous periorbital edema with violaceous hue, right cervical lymphadenopathy, and mild friction rub on the lower zone of the right lung. She had tenderness of the wrists, proximal metacarpal joints, and shoulders; movement restriction due to pain was noticed. Cardiovascular, breast, and abdominal examinations were uneventful.

Electrocardiography showed a sinus rhythm with a regular rate and no abnormalities. A chest X-ray showed pleural thickening at the right lung base.

The patient was admitted to the internal medicine department for further investigations. Abdominal ultrasound was normal with no abdominal lymphadenopathy. CT chest with contrast showed right lateral pleurodiaphragmatic adhesions and fibrotic bands.

Laboratory investigations revealed mild lymphopenia, an elevated serum ferritin level, and a mildly elevated erythrocyte sedimentation rate (Tables 1 and 2).

The echocardiogram showed a normal left ventricular cavity size with a preserved ventricular ejection fraction of 55%, and the systolic pulmonary artery pressure was 21 mmHg.

For this case, it was of interest to draw a list of differential diagnosis that includes sarcoidosis, Still’s disease, systemic lupus erythematosus, rheumatoid arthritis, amyloidosis, chronic blepharitis, eczema, contact dermatitis, psoriasis, and lymphoma. Still’s disease was brought to attention due to an elevated ferritin level; however, there was absence of the classic triad of persistent high-grade fever, joint pain, and a distinctive salmon-colored skin lesion.

Therefore, it remained unclear whether it was systemic lupus erythematosus or amyloidosis until skin biopsy from the eyelid was attempted, and the histopathology results showed degeneration with follicular plugging and dermal inflammatory cell infiltrate. These features were consistent with lupus erythematosus with skin involvement (Figure 1).

On her arrival, her vitals were normal and stable. Clinical examination revealed bilateral erythematous periorbital edema with violaceous hue, right cervical lymphadenopathy, and mild friction rub on the lower zone of the right lung. She had tenderness of the wrists, proximal metacarpal joints, and shoulders; movement restriction due to pain was noticed. Cardiovascular, breast, and abdominal examinations were uneventful.

Laboratory investigations revealed mild lymphopenia, an elevated serum ferritin level, and a mildly elevated erythrocyte sedimentation rate (Tables 1 and 2).

The echocardiogram showed a normal left ventricular cavity size with a preserved ventricular ejection fraction of 55%, and the systolic pulmonary artery pressure was 21 mmHg.

For this case, it was of interest to draw a list of differential diagnosis that includes sarcoidosis, Still’s disease, systemic lupus erythematosus, rheumatoid arthritis, amyloidosis, chronic blepharitis, eczema, contact dermatitis, psoriasis, and lymphoma. Still’s disease was brought to attention due to an elevated ferritin level; however, there was absence of the classic triad of persistent high-grade fever, joint pain, and a distinctive salmon-colored skin lesion.

Therefore, it remained unclear whether it was systemic lupus erythematosus or amyloidosis until skin biopsy from the eyelid was attempted, and the histopathology results showed degeneration with follicular plugging and dermal inflammatory cell infiltrate. These features were consistent with lupus erythematosus with skin involvement (Figure 1).
Figure 1: Skin with focal basal cell damage and vacuolar degeneration. There is follicular plugging with a mild dermal inflammatory cell infiltrate. There is no evidence of malignancy. The features are consistent with cutaneous lupus.

Table 3: A summary of similar presentations that found in different case reports.

<td>Discoid lupus erythematosus of the periorbital edema: clinical dilemmas and diagnostic delays [10]</td>
<td>2012</td>
<td>A 50-year-old Caucasian woman presented with a complaint of painless and slowly progressive right periorbital swelling</td>
<td>The article did not mention the serology study</td>
<td>Biopsy showed perivascular lymphocytic infiltrate throughout the dermis and the basal epidermal layer, with florid lichenoid changes and vacuolar degeneration which were consistent with DLE</td>
<td>Oral corticosteroid was started, with improvement noticed over 12 months</td>
</tr>
<tr>
<td>Eyelid discoid lupus erythematosus and contact dermatitis: a case report [11]</td>
<td>2004</td>
<td>A 71-year-old white female complains of blepharitis with a demarcated area of depigmentation of both lower lid margins</td>
<td>Biopsy showed chronic inflammation which was consistent with DLE</td>
<td>Biopsy showed perivascular lymphocytic infiltrate throughout the dermis and the basal epidermal layer, with florid lichenoid changes and vacuolar degeneration which were consistent with DLE</td>
<td>The patient was treated with hydroxychloroquine with good response</td>
</tr>
<tr>
<td>A 48-year-old Afro-Caribbean female complains of blepharitis with a demarcated area of depigmentation of both lower lid margins</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>The patient was started on hydroxychloroquine, but due to poor compliance there was no response</td>
</tr>
<tr>
<td>A 23-year-old Afro-Caribbean male complains of persistent right lower lid swelling</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Periorbital edema and erythema: an unusual localization of DLE in a patient with psoriasis [12]</td>
<td>2010</td>
<td>A 33-year-old woman presented with complaint of malar erythema and left eye periorbital swelling for 2 years</td>
<td>Antinuclear antibodies and anti-DNA antibodies were negative</td>
<td>Biopsy showed basal cell vacuolar alteration. Showed IgA, IgG, IgM, and C3 intense granular deposits in a band-like pattern along the dermo-epidermal junction</td>
<td>Treatment with chloroquine 250 mg/day for 3 months. But this was stopped due to side effects and treatment was changed to corticosteroid</td>
</tr>
<tr>
<td>Severe chronic blepharitis and scarring ectropion associated with discoid lupus erythematosus [13]</td>
<td>2013</td>
<td>A 45-year-old Caucasian woman presented with complaint of eyelid redness and irritation for 21 years</td>
<td>Antinuclear antibodies were negative</td>
<td>Biopsy showed hyperkeratosis of the epithelium and a thick basement membrane and a sign of chronic inflammation which was consistent with DLE</td>
<td>The patient was started on hydroxychloroquine 200 mg bid po, with improvement noticed over 2 months</td>

</table>
disorders, with possibility of neoplasm or connective tissue
disease. Wu et al. reviewed 25 patients presented primarily
with periorbital edema with a diagnosis of cutaneous lupus
in addition to reviewing 10 cases from the literature. The
majority of the patients were females (68%), and only four of
the 25 patients had bilateral involvement. Seventy-two
percent had their upper eyelid involved. Majority of the
patients were misdiagnosed or suspected to have contact
dermatitis, dermatomyositis, lymphoproliferative neoplasm,
facial cellulitis, and severe angioedema. Our patient was a
female with bilateral eyelid erythematous edema. The initial
impression was of an allergic reaction and angioedema.
Nineteen of the 25 patients as well as our patient had a
negative ANA rate in that study (Table 3).

There is a broad implication of shared histological fea-
tures in lupus erythematosus; 80% of patients had basal cell
vacuolar degeneration, 44% had lymphocytic infiltration,
and 40% had follicular plugging. Those findings were
consistent with our case.

Although our case showed features such as arthritis,
pleuritic thickening, and initial lymphopenia, the serologic
profile came negative. Wu et al. reported 6 patients, who
initially presented with periorbital edema and developed
systemic involvement, meeting the American College of
Rheumatology criteria for diagnosing systemic lupus. Fur-
thermore, Wu et al. found that 10 cases with lupus eryth-
ematosus were reported in the literature with primary
presentation of periorbital erythematous edema. Of those, 9
were females, and 6 had a positive ANA. Similarly, cases
were misdiagnosed as lymphoproliferative disease, ble-
pharitis, and chalazion.

4. Conclusion

Isolated bilateral orbital edema is an extremely rare pre-
sentation and found possible to be presented before other
skin lesions, the challenges with negative serology impact on
diagnosis for cutaneous lupus erythematous, and therefore,
these cases are treated as chronic eczema or angioedema. It is
essential for patients presenting with eyelid lesions and who
fail the treatment for eczema or infections to have a full
careful skin examination and skin biopsy for diagnosis.

Conflicts of Interest

The authors declare that they have no conflicts of interest.
