Recommended by Yong Zhou

We present dynamical analysis of discrete-time delayed neural networks with impulsive effect. Under impulsive effect, we derive some new criteria for the invariance and attractivity of discrete-time neural networks by using decomposition approach and delay difference inequalities. Our results improve or extend the existing ones.

1. Introduction

As we know, the mathematical model of neural network consists of four basic components: an input vector, a set of synaptic weights, summing function with an activation, or transfer function, and an output. From the viewpoint of mathematics, an artificial neural network corresponds to a nonlinear transformation of some inputs into certain outputs. Due to their promising potential for tasks of classification, associative memory, parallel computation and solving optimization problems, neural networks architectures have been extensively researched and developed [1–25]. Most of neural models can be classified as either continuous-time or discrete-time ones. For relative works, we can refer to [20, 24, 26–28].

However, besides the delay effect, an impulsive effect likewise exists in a wide variety of evolutionary process, in which states are changed abruptly at certain moments of time [5, 29]. As is well known, stability is one of the major problems encountered in applications, and has attracted considerable attention due to its important role in applications. However, under impulsive perturbation, an equilibrium point does not exist in many physical systems, especially, in nonlinear dynamical systems. Therefore, an interesting subject is to discuss the invariant sets and the attracting sets of impulsive systems. Some significant progress has been made in the techniques and methods of determining the invariant sets and attracting sets for delay difference equations with discrete variables, delay differential equations, and impulsive
By the above-mentioned papers and discussion, we here make a first attempt to arrive at results on the invariant sets and attracting sets of discrete-time neural networks with impulses and delays.

2. Preliminaries

In this paper, we consider the following discrete-time networks under impulsive effect:

\[ x_i(k) = e^{-a_i h} x_i(k-1) + \frac{1 - e^{-a_i h}}{a_i} \sum_{j=1}^{n} b_{ij} f_j(x_j(k-\tau)) + \frac{1 - e^{-a_i h}}{a_i} c_i, \quad k \geq k_0, \quad k \neq k_l, \]

\[ x_i(k_l) = I_{il}(x_i(k_l^-)), \quad i = 1, 2, \ldots, n, \quad l = 1, 2, \ldots, \]

where \( b_{ij}, c_i (i, j = 1, 2, \ldots, n) \) are real constants, \( a_i (i = 1, 2, \ldots, n); h, \tau \) are positive real numbers such that \( \tau > 1, k_l (l = 1, 2, \ldots) \) is an impulsive sequence such that \( k_1 < k_2 < \cdots < k_l < \cdots \) and \( \lim_{l \to \infty} k_l = \infty \).

By a solution of (2.1), we mean a piecewise continues real-valued function \( x_i(k) \) defined on the interval \([k_0 - \tau, \infty)\) which satisfies (2.1) for all \( k \geq k_0 \).

In the sequel, by \( \Phi_i \) we will denote the set of all continuous real-valued function \( x_i(k) \) defined on the interval \([k_0 - \tau, \infty)\), which satisfies the compatibility condition:

\[ \phi_i(k_0) = e^{-a_i h} \phi_i(k_0 - 1) + \sum_{j=1}^{n} b_{ij} f_j(\phi_j(k-\tau)) + \frac{1 - e^{-a_i h}}{a_i} c_i, \]

(2.2)

By the method of steps, one can easily see that, for any given initial function \( \phi_i \in \Phi_i \), there exists a unique solution \( x_i(k) \) (\( i = 1, 2, \ldots, n \)) of (2.1) which satisfies the initial condition:

\[ x_i(k) = \phi_i(k), \quad \text{for} \quad k \in [k_0 - \tau, k_0], \]

(2.3)

this function will be called the solution of the initial problem (2.1)–(2.3).

For convenience, we rewrite (2.1) and (2.3) into the following vector form

\[ x(k) = Ax(k-1) + Bf(x(k-\tau)) + C, \quad k \geq k_0, \quad k \neq k_l, \]

\[ x(k_l) = I_l(x(k_l^-)), \quad l = 1, 2, \ldots, \]

\[ x(k) = \phi(k), \quad k \in [k_0 - \tau, k_0], \]

(2.4)

where \( x(k) = (x_1(k), x_2(k), \ldots, x_n(k))^T, A = \text{diag}\{e^{-a_1 h}, e^{-a_2 h}, \ldots, e^{-a_n h}\}, B = ((1 - e^{-a_i h} / a_i)b_{ij})_{n \times n}, C = \text{diag}\{((1 - e^{-a_1 h}) / a_1)c_1, ((1 - e^{-a_2 h}) / a_2)c_2, \ldots, ((1 - e^{-a_n h}) / a_n)c_n\}, f(x) = (f_1(x), f_2(x), \ldots, f_n(x))^T, I_l(x) = (I_{l1}(x), I_{l2}(x), \ldots, I_{ln}(x))^T, \) and \( \phi = (\phi_1, \phi_2, \ldots, \phi_n)^T \in \Phi, \) in which \( \Phi = (\Phi_1, \Phi_2, \ldots, \Phi_n)^T. \)

In what follows, we will introduce some notations and basic definitions.
Let $\mathbb{R}^n$ be the space of $n$-dimensional real column vectors and let $\mathbb{R}^{m \times n}$ denote the set of $m \times n$ real matrices. $E$ denotes an identical matrix with appropriate dimensions. For $A, B \in \mathbb{R}^{m \times n}$ or $A, B \in \mathbb{R}^n, A \geq B$ ($A > B$) means that each pair of corresponding elements of $A$ and $B$ satisfies the inequality $\geq$ ($>)$. Particularly, $A$ is called a nonnegative matrix if $A \geq 0$ and is denoted by $A \in \mathbb{R}^{m \times n}_+$ and $z$ is called a positive vector if $z > 0$. $\rho(A)$ denotes the spectral radius of $A$.

$C[X, Y]$ denotes the space of continuous mappings from the topological space $X$ to the topological space $Y$.

$PC[I, \mathbb{R}^n] \triangleq \{ \phi : I \rightarrow \mathbb{R}^n \mid \phi(k^+) \text{ and } \phi(k^-) \text{ exist for } k \in I, \phi(k^+) = \phi(k) \text{ for } k \in I \text{ and } \phi(k-) = \phi(k) \text{ except for points } k_i \in I \}$, where $I \subset \mathbb{R}$ is an interval, $\phi(k^+)$ and $\phi(k^-)$ denote the right limit and left limit of function $\phi(k)$, respectively. Especially, let $PC = PC([k_0, \tau), \mathbb{R})$.

Definition 2.1. The set $S \subset \mathbb{R}^n$ is called a positive invariant set of (2.4), if for any initial value $\phi \in S$, one has the solution $x(k) \in S$ for $k \geq k_0$.

Definition 2.2. The set $S \subset \mathbb{R}^n$ is called a global attracting set of (2.4), if for any initial value $\phi \in PC$, the solution $x(k)$ converges to $S$ as $k \rightarrow +\infty$. That is,

$$\text{dist}(x(k), S) \rightarrow 0, \quad \text{as } k \rightarrow +\infty,$$

(2.5)

where $\text{dist}(x, S) = \inf_{y \in S} d(x, y); (x, y) = \sup_{k \in \mathbb{K}} |x(k) - y(k)|$. In particular, $S = \{0\}$ is called asymptotically stable.

Following [33], we split the matrices $A, B$ into two parts, respectively,

$$A = A^+ - A^-, \quad B = B^+ - B^-, \quad C = C^+ - C^- \quad (2.6)$$

with $a^+_i = \max\{a_i, 0\}, a^-_i = \min\{-a_i, 0\}, b^+_ij = \max\{(1 - e^{-a_i h})/a_i b_{ij}, 0\}, b^-ij = \max\{-(1 - e^{-a_i h})/a_i b_{ij}, 0\}, c^+_i = \max\{(1 - e^{-a_i h})/a_i c_i, 0\}, c^-_i = \max\{-(1 - e^{-a_i h})/a_i c_i, 0\}$.

Then the first equation of (2.4) can be rewritten as

$$x(k) = (A^+ - A^-)x(k - 1) + (B^+ - B^-)f(x(k - \tau)) + (C^+ - C^-). \quad (2.7)$$

Now take the symmetric transformation $y = -x$. From (2.7), it follows that

$$x(k) = A^+ x(k - 1) + A^- y(k - 1) + B^+ f(x(k - \tau)) + B^- g(y(k - \tau)) + (C^+ - C^-),$$

$$y(k) = A^+ y(k - 1) + A^- x(k - 1) + B^+ g(y(k - \tau)) + B^- f(x(k - \tau)) + (C^- - C^+), \quad (2.8)$$

where $f(-u) = -g(u)$.  

Set
\[ z(k) = \begin{pmatrix} x(k) \\ y(k) \end{pmatrix}, \quad h(z(k)) = \begin{pmatrix} f(x(k)) \\ g(y(k)) \end{pmatrix}, \]
\[ \mathcal{A} = \begin{pmatrix} A^+ & A^- \\ A^- & A^+ \end{pmatrix}, \quad \mathcal{B} = \begin{pmatrix} B^+ & B^- \\ B^- & B^+ \end{pmatrix}, \quad \mathcal{C} = \begin{pmatrix} C^+ & -C^- \\ -C^- & C^+ \end{pmatrix}. \]  

By virtue of (2.8) and (2.7), we have
\[ z(k) = \mathcal{A}z(k-1) + \mathcal{B}h(z(k-\tau)) + \mathcal{C}. \]  

Set \( I_i(-v) = -J_i(v) \), in view of the impulsive part of (2.4), we also have \( x(k_i) = I_i(x(k_i^-)) \), \( y(k_i) = J_i(y(k_i^-)) \), and so we have
\[ z(k_i) = \omega_l(z(k_i^{-})), \quad l = 1, 2, \ldots, \]  
where \( \omega_l(z) = (I_i(x)^T, J_i(y)^T)^T \).

**Lemma 2.3** (see [34]). Suppose that \( M \in \mathbb{R}^{n \times n}_+ \) and \( \rho(M) < 1 \), then there exists a positive vector \( z \) such that
\[ (E - M)z > 0. \]  

For \( M \in \mathbb{R}^{n \times n}_+ \) and \( \rho(M) < 1 \), one denotes
\[ \Omega_{\rho}(M) = \{ z \in \mathbb{R}^n \mid (E - M)z > 0, \ z > 0 \}. \]  

By Lemma 2.3, we have the following result.

**Lemma 2.4.** \( \Omega_{\rho}(M) \) is nonempty, and for any scalars \( k_1 > 0, k_2 > 0 \) and vectors \( z_1, z_2 \in \Omega_{\rho}(M) \), one has
\[ k_1z_1 + k_2z_2 \in \Omega_{\rho}(M). \]  

**Lemma 2.5.** Assume that \( u(k) = (u_1(k), u_2(k), \ldots, u_n(k))^T \in C[[k_0, \infty), \mathbb{R}^n] \) satisfy
\[ u(k) \leq Mu(k - 1) + Nu(k - \tau) + J, \quad k \geq k_0, \]
\[ u(\theta) \in PC, \quad \theta \in [k_0 - \tau, k_0], \]  
where \( M = (m_{ij}) \in \mathbb{R}^{n \times n}_+ \), \( N = (n_{ij}) \in \mathbb{R}^{n \times n}_+ \), \( J \in \mathbb{R}^n \).

If \( \rho(M + N) < 1 \), then there exists a positive vector \( v = (v_1, v_2, \ldots, v_n)^T \) such that
\[ u(k) \leq ve^{-\lambda(k-k_0)} + (E - M - N)^{-1}J, \quad k \geq k_0, \]  

where \( \lambda = \max_{i \in I} \lambda_i \).
where $\lambda > 0$ is a constant and defined as

\[
(E - Me^\lambda - Ne^{\lambda\tau})\nu \geq 0
\]  

(2.17)

for the given $\nu$.

Proof. Since $M, N \in \mathbb{R}^{n\times n}$ and $p(M + N) < 1$, by Lemma 2.3, there exists a positive vector $p \in \Omega_p(M + N)$ such that $(E - M - N)p > 0$.

Set $H_1(\lambda) = p_i - \sum_{j=1}^{n}(m_{ij}e^\lambda + n_{ij}e^{\lambda\tau})p_j$ ($i = 1, 2, \ldots, n$), then we have

\[
H_1(\lambda) = -\sum_{j=1}^{n}(m_{ij}e^\lambda + n_{ij}e^{\lambda\tau})p_j < 0.
\]  

(2.18)

Due to

\[
H_1(0) = p_i - \sum_{j=1}^{n}(m_{ij} + n_{ij})p_j > 0,
\]  

(2.19)

there must exist a $\lambda > 0$, such that

\[
\sum_{j=1}^{n}(m_{ij}e^\lambda + n_{ij}e^{\lambda\tau})p_j \leq p_i, \quad i = 1, 2, \ldots, n.
\]  

(2.20)

For $u(\theta) \in PC, \theta \in [k_0 - \tau, k_0]$, there exists a positive constant $l > 1$ such that

\[
u(\theta) \leq lp e^{-\lambda(\theta - k_0)} + W, \quad \theta \in [k_0 - \tau, k_0],
\]  

(2.21)

where $W = (E - M - N)^{-1}J$.

By Lemma 2.4, $lp \in \Omega_{p}(M + N)$. Without loss of generality, we can find a $\nu \in \Omega_p(M + N)$ such that

\[
\sum_{j=1}^{n}(m_{ij}e^\lambda + n_{ij}e^{\lambda\tau})\nu_j \leq \nu_i, \quad i = 1, 2, \ldots, n,
\]  

(2.22)

\[
u(\theta) \leq \nu e^{-\lambda(\theta - k_0)} + W, \quad \theta \in [k_0 - \tau, k_0].
\]  

(2.23)

Set $u(k) = \nu(k)e^{-\lambda(k-k_0)} + W, k \geq k_0$, substituting this into (2.15), we have

\[
u(k) \leq Me^\lambda\nu(k - 1) + Ne^{\lambda\tau}\nu(k - \tau).
\]  

(2.24)

By (2.23), we get that

\[
u(\theta) \leq \nu, \quad \theta \in [k_0 - \tau, k_0].
\]  

(2.25)
Next, we will prove for any \( k \geq k_0, \)
\[
\nu(k) \leq \nu. \tag{2.26}
\]

To this end, we consider an arbitrary number \( \varepsilon > 0, \) we claim that
\[
\nu(k) < (1 + \varepsilon)\nu, \quad k \geq k_0. \tag{2.27}
\]

Otherwise, by the continuity of \( u(k), \) there must exist a \( k^* > k_0 \) and index \( r \) such that
\[
\nu(k^*) = (1 + \varepsilon)\nu_r. \tag{2.28}
\]

Then, by using (2.24) and (2.28), from (2.22), we obtain
\[
(1 + \varepsilon)\nu_r = \nu_r(k^*) \leq \sum_{j=1}^{n} \left( m_{rj}e^jv_j(k^* - 1) + n_{rj}e^{\lambda\tau}v_j(k^* - \tau) \right)
\leq \sum_{j=1}^{n} \left( m_{rj}e^j + n_{rj}e^{\lambda\tau} \right)(1 + \varepsilon)v_j
\leq (1 + \varepsilon)v_r,
\]
which is a contradiction. Hence, (2.27) holds for all numbers \( \varepsilon > 0. \) It follows immediately that (2.26) is always satisfied, which can easily be led to (2.16). This completes the proof. \( \square \)

3. Main Results

For convenience, we introduce the following assumptions.

\((H_1)\) For any \( x, y \in \mathbb{R}^n, \) there exist a nonnegative matrix \( P = (p_{ij})_{n \times n} \geq 0 \) and a nonnegative vector \( \mu = (\mu_1, \mu_2, \ldots, \mu_n)^T \geq 0 \) such that
\[
f(x) - f(y) \leq P(x - y) + \mu. \tag{3.1}
\]

\((H_2)\) For any \( x, y \in \mathbb{R}^n, \) there exist nonnegative matrices \( Q_l = (q_{ij}^l)_{n \times n} \geq 0 \) and a nonnegative vector \( \nu = (\nu_1, \nu_2, \ldots, \nu_n)^T \geq 0 \) such that
\[
I_l(x) - I_l(y) \leq Q_l(x - y) + \nu, \quad l = 1, 2, \ldots. \tag{3.2}
\]

\((H_3)\) Also \( \rho(\mathcal{A} + \mathcal{B}P) < 1 \) and \( \rho(Q_l) < 1, \quad l = 1, 2, \ldots, \) where \( \mathcal{P} = \text{diag}\{P, P\}, \) \( Q_l = \text{diag}\{Q_l, Q_l\}. \)

\((H_4)\) Also \( \Omega = \bigcap_{l=1}^{\infty} [\Omega_{\rho}(Q_l)] \cap \Omega_{\rho}(\mathcal{A} + \mathcal{B}P) \) is nonempty.
Theorem 3.1. Assume that \((H_1)-(H_4)\) hold. Then there exists a positive vector \(\eta = (\alpha^T, \beta^T)^T \in \Omega\) such that \(S = \{ \phi \in PC \mid -\beta \leq \phi \leq \alpha \}\) is a positive invariant set of (2.4), where \(\alpha \geq 0, \beta \geq 0, \alpha, \beta \in \mathbb{R}^n\).

Proof. From \((H_1)\) and \((H_2)\), we can claim that for any \(z \in \mathbb{R}^n\),

\[
h(z) \leq Dz + \Lambda,\]
\[
\omega_l(z) \leq Q_l z(k_l^-) + \Gamma, \quad l = 1, 2, \ldots,
\]

where \(\Lambda = ((\mu + |f(0)|)^T, (\mu + |f(0)|)^T)^T\) and satisfied \(B\Lambda + C > 0, \Gamma = ((\nu + |f(0)|)^T, (\nu + |f(0)|)^T)^T\).

So, by using (2.10) and (2.11) and taking into account (3.3), we get

\[
z(k) \leq A z(k-1) + B \rho z(k-\tau) + B \Lambda + C,
\]
\[
z(k_l) \leq Q_l z(k_l^-) + \Gamma, \quad l = 1, 2, \ldots,
\]

respectively.

By assumptions \((H_3), (H_4)\) and Lemma 2.3, there exists a positive vector \(\eta_1 \in \Omega\) such that

\[
(E - A - B \rho) \eta_1 > 0,
\]
\[
(E - Q_l) \eta_1 > 0, \quad l = 1, 2, \ldots
\]

Since \(B \Lambda + C\) and \(\Gamma\) are positive constant vectors, by (3.6), there must exist two scalars \(k_1 > 0, k_2 > 0\) such that

\[
(E - A - B \rho) k_1 \eta_1 \geq B \Lambda + C,
\]
\[
(E - Q_l) k_2 \eta_1 \geq \Gamma, \quad l = 1, 2, \ldots
\]

respectively.

Set

\[
\eta = \left( \alpha^T, \beta^T \right)^T \triangleq \max \{ k_1 \eta_1, k_2 \eta_1 \},
\]

by Lemma 2.4, clearly, \(\eta \in \Omega\) and

\[
(E - A - B \rho) \eta \geq B \rho + C,
\]
\[
(E - Q_l) \eta \geq \Gamma, \quad l = 1, 2, \ldots
\]

Next, we will prove, for any \(-\beta \leq \phi \leq \alpha\), that is, \(z(k) \leq \eta, k \in [k_0 - \tau, k_0]\),

\[
z(k) \leq \eta, \quad k \in [k_0, k_1].
\]
In order to prove (3.11), we first prove, for any \(\varepsilon > 0\),

\[
z(k) < (1 + \varepsilon)\eta, \quad k \in [k_0, k_1]. \tag{3.12}
\]

If (3.12) is false, by the piecewise continuous nature of \(z(k)\), there must exist a \(k^* \in [k_0, k_1]\) and an index \(q\) such that

\[
z(k^*) = (1 + \varepsilon)\eta_q. \tag{3.13}
\]

Denoting \(A = (c_{ij})_{2n \times 2n}, B = (d_{ij})_{2n \times 2n}, B\Lambda + C = (\lambda_1, \lambda_2, \ldots, \lambda_{2n}),\) we get

\[
(1 + \varepsilon)\eta_q = z_q(k^*) \leq \sum_{j=1}^{2n} (c_{qj}z_j(k^* - 1) + d_{qj}z_j(k^* - \tau)) + \lambda_q
\]
\[
< \sum_{j=1}^{2n} (c_{qj} + d_{qj})(1 + \varepsilon)\eta_j + \lambda_q
\]
\[
\leq (1 + \varepsilon)(\eta_q - \lambda_q) + \lambda_q
\]
\[
< (1 + \varepsilon)\eta_q.
\]

This is a contradiction and hence (3.12) holds. From the fact that (3.12) is fulfilled for any \(\varepsilon > 0\), it follows immediately that (3.11) is always satisfied.

On the other hand, by using (3.5), (3.10), and (3.11), we obtain that

\[
z(k_1) \leq Q_1 z(k_1^-) + \Gamma \leq Q_1 \eta + \Gamma \leq \eta. \tag{3.15}
\]

Therefore, we can claim that

\[
z(k) \leq \eta, \quad k \in [k_1 - \tau, k_1]. \tag{3.16}
\]

In a similar way to the proof of (3.11), we can proof that (3.16) implies

\[
z(k) \leq \eta, \quad k \in [k_1, k_2]. \tag{3.17}
\]

Hence, by the induction principle, we conclude that

\[
z(k) \leq \eta, \quad k \in [k_{l-1}, k_l), \quad l = 1, 2, \ldots,
\]

which implies \(z(k) \leq \eta\) holds for any \(k \geq k_0\), that is, \(-\beta \leq x(k) \leq \alpha\) for any \(k \geq k_0\). This is completes the proof of the theorem. \qed
Remark 3.2. In fact, under the assumptions of Theorem 3.1, the $\eta$ must exist, for example, since $\rho(\mathcal{A} + \mathcal{B}D) < 1$ and $\rho(Q_l) < 1$ imply $(E - \mathcal{A} - \mathcal{B}D)^{-1} > 0$ and $(E - Q_l)^{-1} > 0$, respectively, so we may take $\eta$ as the follows:

$$\eta = \max \left\{ (E - \mathcal{A} - \mathcal{B}D)^{-1} (\mathcal{B} \Lambda + C), (E - Q_l)^{-1} \Gamma \right\}. \quad (3.19)$$

Theorem 3.3. If assumptions $(H_1)$–$(H_4)$ hold, then the $S = \{ \phi \in PC \mid -\beta \leq \phi \leq \alpha \}$ is a global attracting set of (2.4), where $\alpha \geq 0, \beta \geq 0, \alpha, \beta \in \mathbb{R}^n$, and the vector $\eta = (\alpha^T, \beta^T)^T$ is chosen as (3.19).

Proof. From (3.4), assumption $(H_3)$ and Lemma 2.5, and taking into account the definition of $\eta$, we obtain that

$$z(k) \leq ze^{-\lambda(k-k_0)} + (E - \mathcal{A} - \mathcal{B}D)^{-1} (\mathcal{B} \Lambda + C) \leq ze^{-\lambda(k-k_0)} + \eta, \quad k \neq k_l, \ l = 1, 2, \ldots, \quad (3.20)$$

where the positive vector $z \in \Omega$ and $\lambda > 0$ satisfying

$$\left( E - \mathcal{A} e^{\lambda} - \mathcal{B} D e^{\lambda \tau} \right) z \geq 0. \quad (3.21)$$

From (3.15) and taking into account the definition of $z, \eta$, we get that

$$z(k_1) \leq Q_1 z(k_1) + \Gamma \leq Q_1 ze^{-\lambda(k_1-k_0)} + Q_1 \eta + \Gamma \leq ze^{-\lambda(k_1-k_0)} + \eta. \quad (3.22)$$

Therefore, we have that

$$z(k) \leq ze^{-\lambda(k-k_0)} + \eta, \quad k \in [k_1, k_2), \quad (3.23)$$

By using (3.20), (3.23) and Lemma 2.5 again, we obtain that

$$z(k) \leq ze^{-\lambda(k-k_0)} + \eta, \quad k \in [k_1, k_2), \quad (3.24)$$

Hence, by the induction principle, we conclude that

$$z(k) \leq ze^{-\lambda(k-k_0)} + \eta, \quad k \in [k_0, k_1), \ l = 1, 2, \ldots, \quad (3.25)$$

which implies that the conclusion holds. The proof is complete. $\Box$
4. An Illustrative Example

Consider the system (2.1) with the following parameters \((n = 2, i, j = 1, 2)\) \(a_i = 1/4\), \(b_{ij} = 1/4\), \(c_i = 1/4\), \(p_{ij} = 3/8\), \(q_{ij} = 1/4\), \(f_j(x_j) = \sin(x_j)\), \(I_{il}(x_i) = \cos(x_i)\), \(h = 1\), \(l = 1\),

\[
\Lambda = \begin{pmatrix}
10 & 4 \\
6 & 3 \\
7 & 8 \\
4 & 5 \\
\end{pmatrix}, \quad \Gamma = \begin{pmatrix}
8 & 4 \\
3 & 9 \\
6 & 2 \\
5 & 7 \\
\end{pmatrix}.
\quad (4.1)
\]

From the given parameters, we have

\[
\mathcal{A} = \begin{pmatrix}
\frac{1}{4} & 0 & 0 & 0 \\
0 & \frac{1}{4} & 0 & 0 \\
0 & 0 & \frac{1}{4} & 0 \\
0 & 0 & 0 & \frac{1}{4} \\
\end{pmatrix}, \quad \mathcal{B} = \begin{pmatrix}
1 - e^{-1/4} & 1 - e^{-1/4} & 0 & 0 \\
1 - e^{-1/4} & 1 - e^{-1/4} & 0 & 0 \\
0 & 0 & 1 - e^{-1/4} & 1 - e^{-1/4} \\
0 & 0 & 1 - e^{-1/4} & 1 - e^{-1/4} \\
\end{pmatrix}.
\]

\[
\mathcal{C} = \begin{pmatrix}
1 - e^{-1/4} & 0 \\
0 & 1 - e^{-1/4} \\
-(1 - e^{-1/4}) & 0 \\
0 & -(1 - e^{-1/4}) \\
\end{pmatrix}, \quad \mathcal{P} = \begin{pmatrix}
\frac{3}{8} & \frac{3}{8} & 0 & 0 \\
\frac{3}{8} & \frac{3}{8} & 0 & 0 \\
0 & 0 & \frac{3}{8} & \frac{3}{8} \\
0 & 0 & \frac{3}{8} & \frac{3}{8} \\
\end{pmatrix}, \quad Q_1 = \begin{pmatrix}
\frac{1}{4} & \frac{1}{4} & 0 & 0 \\
\frac{1}{4} & \frac{1}{4} & 0 & 0 \\
0 & 0 & \frac{1}{4} & \frac{1}{4} \\
0 & 0 & \frac{1}{4} & \frac{1}{4} \\
\end{pmatrix}.
\quad (4.2)
\]

Obviously, according to Theorems 3.1 and 3.3, the \(S = \{\phi \in PC \mid -\beta \leq \phi \leq \alpha\}\) is the invariant and global attracting set of (2.4).

5. Conclusion

In this paper, by using \(M\)-matrix theory and decomposition approach, some new criteria for the invariance and attractivity of discrete-time neural networks have been obtained. Moreover, these conditions can be easily checked in practice.
