A function $f : \mathbb{R} \rightarrow \mathbb{R}$ is said to be a Fibonacci function if $f(x+2) = f(x+1) + f(x)$ for all $x \in \mathbb{R}$. In 2012, some properties on the Fibonacci functions were presented. In this paper, for any positive integer k , a function $f : \mathbb{R} \rightarrow \mathbb{R}$ is said to be a Fibonacci function with period k if $f(x+2k) = f(x+k) + f(x)$ for all $x \in \mathbb{R}$; we present some properties on the Fibonacci functions with period k .

1. Introduction

Presently, there are many research articles about Fibonacci numbers (see [1]). Fibonacci numbers are also involved in the golden ratio (see [2]). In 2008, Kim and Neggers [3] studied Fibonacci means. In 2009, Jung [4] studied Hyers-Ulam stability of Fibonacci functional equation. In 2010, Han et al. [5] studied a Fibonacci norm of positive integers. In 2012, Han et al. [6] studied Fibonacci sequences in groupoids. Moreover, they [7] gave some properties on Fibonacci functions; a function $f : \mathbb{R} \rightarrow \mathbb{R}$ is said to be a Fibonacci function if $f(x+2) = f(x+1) + f(x)$, for all $x \in \mathbb{R}$, using the concept of f -even and f -odd functions. They also showed that if f is a Fibonacci function, then $\lim_{x \rightarrow \infty} f(x+1)/f(x) = (1+\sqrt{5})/2$.

In this paper, for any positive integer k , a function $f : \mathbb{R} \rightarrow \mathbb{R}$ is said to be a Fibonacci function with period k if $f(x+2k) = f(x+k) + f(x)$ for all $x \in \mathbb{R}$; we present some properties on the Fibonacci functions with period k using the concept of f -even and f -odd functions with period k . Moreover, we also present some properties on the odd Fibonacci functions with period k .

2. Fibonacci Functions with Period k

Definition 1. Let k be a positive integer. A function $f : \mathbb{R} \rightarrow \mathbb{R}$ is said to be a Fibonacci function with period k if $f(x+2k) = f(x+k) + f(x)$ for all $x \in \mathbb{R}$.

Example 2. Let $f(x) = a^{x/k}$ be a Fibonacci function with period $k \in \mathbb{N}$, where $a > 0$. It follows that $a^{(x/k)+2} = a^{(x/k)+1} + a^{x/k}$ for all $x \in \mathbb{R}$, so $a^2 = a + 1$. Then $a = (1 + \sqrt{5})/2$. Thus, $f(x) = ((1 + \sqrt{5})/2)^{x/k}$ for all $x \in \mathbb{R}$.

Proposition 3. Let $f : \mathbb{R} \rightarrow \mathbb{R}$ be a Fibonacci function with period $k \in \mathbb{N}$. Assume that f is differentiable. Then f' is also a Fibonacci function with period k .

Proof. Let $x \in \mathbb{R}$. Since $f(x+2k) = f(x+k) + f(x)$, it follows that $f'(x+2k) = f'(x+k) + f'(x)$. $\square$

Proposition 4. Let $f : \mathbb{R} \rightarrow \mathbb{R}$ be a Fibonacci function with period $k \in \mathbb{N}$, and define $g_t(x) = f(x+t)$ for all $x \in \mathbb{R}$, where $t \in \mathbb{R}$. Then g_t is also a Fibonacci function with period k .

Proof. Let $x \in \mathbb{R}$. Then $g_t(x+2k) = f(x+2k+t) = f(x+t+k) + f(x+t) = g_t(x+k) + g_t(x)$. $\square$

Example 5. Let $k \in \mathbb{N}$ and $t \in \mathbb{R}$. Define $g_t : \mathbb{R} \rightarrow \mathbb{R}$ by $g_t(x) = ((1 + \sqrt{5})/2)^{(x+t)/k}$ for all $x \in \mathbb{R}$. Then g_t is a Fibonacci function with period k .

Theorem 6. Let $f : \mathbb{R} \rightarrow \mathbb{R}$ be a Fibonacci function with period $k \in \mathbb{N}$, and let $\{F_n\}_{n \in \mathbb{N}}$ be a sequence of Fibonacci numbers with $F_0 = 0$, $F_1 = 1$, and $F_{n+1} = F_n + F_{n-1}$ for all $n \in \mathbb{N}$. Then, for any $n \in \mathbb{N}$ and $x \in \mathbb{R}$, $f(x+nk) = F_n f(x+k) + F_{n-1} f(x)$.

Proof. Let $x \in \mathbb{R}$. We note that $f(x+k) = F_1 f(x+k) + F_0 f(x)$ and $f(x+2k) = F_2 f(x+k) + F_1 f(x)$. Now, we assume that $f(x+nk) = F_n f(x+k) + F_{n-1} f(x)$ and $f(x+(n+1)k) = F_{n+1} f(x+k) + F_n f(x)$, where $n \in \mathbb{N}$. Then

$$\begin{aligned} f(x+(n+2)k) &= f(x+(n+1)k) + f(x+nk) \\ &= F_{n+1} f(x+k) + F_n f(x) + F_n f(x+k) + F_{n-1} f(x) \\ &= (F_{n+1} + F_n) f(x+k) + (F_n + F_{n-1}) f(x) \\ &= F_{n+2} f(x+k) + F_{n+1} f(x). \end{aligned} \quad (1)$$

This proof is completed. $\square$

3. Odd Fibonacci Functions with Period k

Definition 7. Let k be a positive integer. A function $f : \mathbb{R} \rightarrow \mathbb{R}$ is said to be an odd Fibonacci function with period k if $f(x+2k) = -f(x+k) + f(x)$ for all $x \in \mathbb{R}$.

Example 8. Let $f(x) = a^{x/k}$ be an odd Fibonacci function with period $k \in \mathbb{N}$, where $a > 0$. It follows that $a^{(x/k)+2} = -a^{(x/k)+1} + a^{x/k}$ for all $x \in \mathbb{R}$, so $a^2 = -a + 1$. Then $a = (-1 + \sqrt{5})/2$. Thus, $f(x) = ((-1 + \sqrt{5})/2)^{x/k}$ for all $x \in \mathbb{R}$.

Proposition 9. Let $f : \mathbb{R} \rightarrow \mathbb{R}$ be an odd Fibonacci function with period $k \in \mathbb{N}$. Assume that f is differentiable. Then f' is also an odd Fibonacci function with period k .

Proof. Let $x \in \mathbb{R}$. Since $f(x+2k) = -f(x+k) + f(x)$, it follows that $f'(x+2k) = -f'(x+k) + f'(x)$. $\square$

Proposition 10. Let $f : \mathbb{R} \rightarrow \mathbb{R}$ be an odd Fibonacci function with period $k \in \mathbb{N}$, and define $g_t(x) = f(x+t)$ for all $x \in \mathbb{R}$, where $t \in \mathbb{R}$. Then g_t is also an odd Fibonacci function with period k .

Proof. Let $x \in \mathbb{R}$. Then $g_t(x+2k) = f(x+2k+t) = -f(x+t+k) + f(x+t) = -g_t(x+k) + g_t(x)$. $\square$

Example 11. Let $k \in \mathbb{N}$ and $t \in \mathbb{R}$. Define $g_t : \mathbb{R} \rightarrow \mathbb{R}$ by $g_t(x) = ((-1 + \sqrt{5})/2)^{(x+t)/k}$ for all $x \in \mathbb{R}$. Then g_t is an odd Fibonacci function with period k .

Theorem 12. Let $f : \mathbb{R} \rightarrow \mathbb{R}$ be an odd Fibonacci function with period $k \in \mathbb{N}$, and let $\{F_n\}_{n \in \mathbb{N}}$ be a sequence of Fibonacci numbers with $F_0 = 0$, $F_{-1} = 1$, and $F_{-n-1} = -F_n + F_{n+1}$ for all $n \in \mathbb{N}$. Then, for any $n \in \mathbb{N}$ and $x \in \mathbb{R}$, $f(x+nk) = F_n f(x+k) + F_{n-1} f(x)$.

Proof. Let $x \in \mathbb{R}$. We note that $f(x+k) = F_{-1} f(x+k) + F_0 f(x)$ and $f(x+2k) = F_{-2} f(x+k) + F_{-1} f(x)$. Now, we assume that

$f(x+nk) = F_{-n} f(x+k) + F_{-n+1} f(x)$ and $f(x+(n+1)k) = F_{-n-1} f(x+k) + F_{-n} f(x)$, where $n \in \mathbb{N}$. Then

$$\begin{aligned} f(x+(n+2)k) &= -f(x+(n+1)k) + f(x+nk) \\ &= -(F_{-n-1} f(x+k) + F_{-n} f(x)) \\ &\quad + F_{-n} f(x+k) + F_{-n+1} f(x) \\ &= (-F_{-n-1} + F_{-n}) f(x+k) \\ &\quad + (-F_{-n} + F_{-n+1}) f(x) \\ &= F_{-n-2} f(x+k) + F_{-n-1} f(x). \end{aligned} \quad (2)$$

This proof is completed. $\square$

4. f -Even Functions with Period k

Definition 13. Let k be a positive integer and let $\alpha : \mathbb{R} \rightarrow \mathbb{R}$ be such that if $\alpha h = 0$, where $h : \mathbb{R} \rightarrow \mathbb{R}$ is continuous, then $h = 0$. The function α is said to be an f -even function with period k if $\alpha(x+k) = \alpha(x)$ for all $x \in \mathbb{R}$.

Example 14. Define $\alpha(x) = x - \lfloor x \rfloor$ for all $x \in \mathbb{R}$. Let $h : \mathbb{R} \rightarrow \mathbb{R}$ be a continuous function such that $\alpha h = 0$. For any $x \notin \mathbb{Z}$, we have $\alpha(x) \neq 0$, so $h(x) = 0$. Since $\mathbb{R} \setminus \mathbb{Z}$ is dense in $\mathbb{R}$ and h is continuous, it follows that $h = 0$. Let $k \in \mathbb{N}$ and $x \in \mathbb{R}$. Then $\alpha(x+k) = x+k - \lfloor x+k \rfloor = x+k - \lfloor x \rfloor - k = x - \lfloor x \rfloor = \alpha(x)$. Hence, α is an f -even function with period k .

Theorem 15. Let $k \in \mathbb{N}$ and $\alpha : \mathbb{R} \rightarrow \mathbb{R}$ be an f -even function with period k and let $g : \mathbb{R} \rightarrow \mathbb{R}$ be a continuous function. Then g is a Fibonacci function with period k if and only if αg is a Fibonacci function with period k .

Proof. First, we assume that g is a Fibonacci function with period k . For any $x \in \mathbb{R}$, we have

$$\begin{aligned} (\alpha g)(x+2k) &= \alpha(x+2k) g(x+2k) \\ &= \alpha(x+k) (g(x+k) + g(x)) \\ &= \alpha(x+k) g(x+k) + \alpha(x+k) g(x) \\ &= \alpha(x+k) g(x+k) + \alpha(x) g(x) \\ &= (\alpha g)(x+k) + (\alpha g)(x). \end{aligned} \quad (3)$$

Hence, αg is a Fibonacci function with period k .

Next, we assume that αg is a Fibonacci function with period k . Let $x \in \mathbb{R}$. Then

$$\begin{aligned} \alpha(x+k) g(x+2k) &= \alpha(x+2k) g(x+2k) \\ &= (\alpha g)(x+2k) \\ &= (\alpha g)(x+k) + (\alpha g)(x) \end{aligned}$$

$$\begin{aligned}
&= \alpha(x+k)g(x+k) + \alpha(x)g(x) \\
&= \alpha(x+k)g(x+k) + \alpha(x+k)g(x) \\
&= \alpha(x+k)(g(x+k) + g(x)).
\end{aligned} \tag{4}$$

By the assumption of α , we obtain that $g(x+2k) = g(x+k) + g(x)$. Hence, g is a Fibonacci function with period k . $\square$

Example 16. Let $k \in \mathbb{N}$. Define $\alpha(x) = x - \lfloor x \rfloor$ and $g(x) = ((1 + \sqrt{5})/2)^{x/k}$ for all $x \in \mathbb{R}$. For all $x \in \mathbb{R}$, we have $\alpha g(x) = (x - \lfloor x \rfloor)((1 + \sqrt{5})/2)^{x/k}$. We recall that α is an f -even function with period k , and g is a Fibonacci function with period k . Hence, αg is a Fibonacci function with period k .

Theorem 17. Let $k \in \mathbb{N}$ and $\alpha : \mathbb{R} \rightarrow \mathbb{R}$ be an f -even function with period k and let $g : \mathbb{R} \rightarrow \mathbb{R}$ be a continuous function. Then g is an odd Fibonacci function with period k if and only if αg is an odd Fibonacci function with period k .

Proof. First, we assume that g is an odd Fibonacci function with period k . For any $x \in \mathbb{R}$, we have

$$\begin{aligned}
&(\alpha g)(x+2k) \\
&= \alpha(x+2k)g(x+2k) \\
&= \alpha(x+k)(-g(x+k) + g(x)) \\
&= -\alpha(x+k)g(x+k) + \alpha(x+k)g(x) \\
&= -\alpha(x+k)g(x+k) + \alpha(x)g(x) \\
&= -(\alpha g)(x+k) + (\alpha g)(x).
\end{aligned} \tag{5}$$

Hence, αg is an odd Fibonacci function with period k .

Next, we assume that αg is an odd Fibonacci function with period k . Let $x \in \mathbb{R}$. Then

$$\begin{aligned}
&\alpha(x+k)g(x+2k) \\
&= \alpha(x+2k)g(x+2k) \\
&= (\alpha g)(x+2k) \\
&= -(\alpha g)(x+k) + (\alpha g)(x) \\
&= -\alpha(x+k)g(x+k) + \alpha(x)g(x) \\
&= -\alpha(x+k)g(x+k) + \alpha(x+k)g(x) \\
&= \alpha(x+k)(-g(x+k) + g(x)).
\end{aligned} \tag{6}$$

By the assumption of α , we obtain that $g(x+2k) = -g(x+k) + g(x)$. Hence, g is an odd Fibonacci function with period k . $\square$

Example 18. Let $k \in \mathbb{N}$. Define $\alpha(x) = x - \lfloor x \rfloor$ and $g(x) = ((-1 + \sqrt{5})/2)^{x/k}$ for all $x \in \mathbb{R}$. For all $x \in \mathbb{R}$, we have $\alpha g(x) = (x - \lfloor x \rfloor)((-1 + \sqrt{5})/2)^{x/k}$. We recall that α is an f -even

function with period k and g is an odd Fibonacci function with period k . Hence, αg is an odd Fibonacci function with period k .

5. f -Odd Functions with Period k

Definition 19. Let k be a positive integer and let $\alpha : \mathbb{R} \rightarrow \mathbb{R}$ be such that if $\alpha h = 0$ where $h : \mathbb{R} \rightarrow \mathbb{R}$ is continuous, then $h = 0$. The function α is said to be an f -odd function with period k if $\alpha(x+k) = -\alpha(x)$ for all $x \in \mathbb{R}$.

Example 20. Define $\alpha(x) = \sin(\pi x)$ for all $x \in \mathbb{R}$. Let $h : \mathbb{R} \rightarrow \mathbb{R}$ be a continuous function such that $\alpha h = 0$. For any $x \notin \pi\mathbb{Z}$, we have $\alpha(x) \neq 0$, so $h(x) = 0$. Since $\mathbb{R} \setminus \pi\mathbb{Z}$ is dense in $\mathbb{R}$ and h is continuous, it follows that $h = 0$. Let k be a positive odd integer and $x \in \mathbb{R}$. Then $\alpha(x+k) = \sin(\pi(x+k)) = \sin(\pi x + \pi k) = -\sin(\pi x) = -\alpha(x)$. Hence, α is an f -even function with period k .

Theorem 21. Let $k \in \mathbb{N}$ and $\alpha : \mathbb{R} \rightarrow \mathbb{R}$ be an f -odd function with period k and let $g : \mathbb{R} \rightarrow \mathbb{R}$ be a continuous function. Then g is a Fibonacci function with period k if and only if αg is an odd Fibonacci function with period k .

Proof. First, we assume that g is a Fibonacci function with period k . For any $x \in \mathbb{R}$, we have

$$\begin{aligned}
&(\alpha g)(x+2k) \\
&= \alpha(x+2k)g(x+2k) \\
&= -\alpha(x+k)(g(x+k) + g(x)) \\
&= -\alpha(x+k)g(x+k) - \alpha(x+k)g(x) \\
&= -\alpha(x+k)g(x+k) + \alpha(x)g(x) \\
&= -(\alpha g)(x+k) + (\alpha g)(x).
\end{aligned} \tag{7}$$

Hence, αg is an odd Fibonacci function with period k .

Next, we assume that αg is an odd Fibonacci function with period k . Let $x \in \mathbb{R}$. Then

$$\begin{aligned}
&\alpha(x+k)g(x+2k) \\
&= -\alpha(x+2k)g(x+2k) \\
&= -(\alpha g)(x+2k) \\
&= -(-(\alpha g)(x+k) + (\alpha g)(x)) \\
&= (\alpha g)(x+k) - (\alpha g)(x) \\
&= \alpha(x+k)g(x+k) - \alpha(x)g(x) \\
&= \alpha(x+k)g(x+k) + \alpha(x+k)g(x) \\
&= \alpha(x+k)(g(x+k) + g(x)).
\end{aligned} \tag{8}$$

By the assumption of α , we obtain that $g(x+2k) = g(x+k) + g(x)$. Hence, g is a Fibonacci function with period k . $\square$

Example 22. Let k be a positive odd integer. Define $\alpha(x) = \sin(\pi x)$ and $g(x) = ((1 + \sqrt{5})/2)^{x/k}$ for all $x \in \mathbb{R}$. We have $\alpha g(x) = (\sin(\pi x))((1 + \sqrt{5})/2)^{x/k}$ for all $x \in \mathbb{R}$. We recall that α is an f -odd function with period k and g is a Fibonacci function with period k . Hence, αg is an odd Fibonacci function with period k .

Theorem 23. Let $k \in \mathbb{N}$ and $\alpha : \mathbb{R} \rightarrow \mathbb{R}$ be an f -odd function with period k and let $g : \mathbb{R} \rightarrow \mathbb{R}$ be a continuous function. Then g is an odd Fibonacci function with period k if and only if αg is a Fibonacci function with period k .

Proof. First, we assume that g is an odd Fibonacci function with period k . For any $x \in \mathbb{R}$, we have

$$\begin{aligned}
 (\alpha g)(x + 2k) &= \alpha(x + 2k) g(x + 2k) \\
 &= -\alpha(x + k) (-g(x + k) + g(x)) \\
 &= \alpha(x + k) g(x + k) - \alpha(x + k) g(x) \\
 &= \alpha(x + k) g(x + k) + \alpha(x) g(x) \\
 &= (\alpha g)(x + k) + (\alpha g)(x).
 \end{aligned} \tag{9}$$

Hence, αg is a Fibonacci function with period k .

Next, we assume that αg is a Fibonacci function with period k . Let $x \in \mathbb{R}$. Then

$$\begin{aligned}
 \alpha(x + k) g(x + 2k) &= -\alpha(x + 2k) g(x + 2k) \\
 &= -(\alpha g)(x + 2k) \\
 &= -((\alpha g)(x + k) + (\alpha g)(x)) \\
 &= -(\alpha g)(x + k) - (\alpha g)(x) \\
 &= -\alpha(x + k) g(x + k) - \alpha(x) g(x) \\
 &= -\alpha(x + k) g(x + k) + \alpha(x + k) g(x) \\
 &= \alpha(x + k) (-g(x + k) + g(x)).
 \end{aligned} \tag{10}$$

By the assumption of α , we obtain that $g(x + 2k) = -g(x + k) + g(x)$. Hence, g is an odd Fibonacci function with period k . $\square$

Example 24. Let k be a positive odd integer. Define $\alpha(x) = \sin(\pi x)$ and $g(x) = ((-1 + \sqrt{5})/2)^{x/k}$ for all $x \in \mathbb{R}$. We have $\alpha g(x) = (\sin(\pi x))((-1 + \sqrt{5})/2)^{x/k}$ for all $x \in \mathbb{R}$. We recall that α is an f -odd function with period k and g is an odd Fibonacci function with period k . Hence, αg is a Fibonacci function with period k .

6. Open Problems

Conjecture 25. If f is a Fibonacci function with period $k \in \mathbb{N}$, then

$$\lim_{x \rightarrow \infty} \frac{f(x + k)}{f(x)} = \frac{1 + \sqrt{5}}{2}. \tag{11}$$

Conjecture 26. If f is an odd Fibonacci function with period $k \in \mathbb{N}$, then

$$\lim_{x \rightarrow \infty} \frac{f(x + k)}{f(x)} = \frac{-1 - \sqrt{5}}{2}. \tag{12}$$
