Abstract

We study the relationship between DC3 pairs and the set of discontinuities in distribution function. We also check relations between DC3 pairs for a continuous map and its higher iterates.

1. Introduction

In 1994, Schweizer and Smítal extended the definition of Li-Yorke pair for interval maps [1]. The main motivation was that chaotic dynamics, as introduced by Li and Yorke in [2], may be present in an interval map with zero topological entropy, while the adjusted definition can appear only in an interval map with positive topological entropy. The case of interval maps is very special, since in this context there is no difference between maps with DC1 pairs (the strongest possibility of distributional chaos) and DC3 pairs (the weakest possibility).

Let us first give the concepts that originated from [1] (but using modern terminology), since they are the main topics of the present paper.

Suppose that $(X, f)$ is a dynamical system, that is, a continuous map $f : X \to X$ acting on a compact metric space $(X, d)$ (basic definitions related to dynamical systems, such as orbit and $\omega$-limit set, can be found in any standard book on dynamical systems, e.g., [3]). For any positive integer $n$, points $x, y \in X$, and real number $t > 0$, let

$$
\xi_f (x, y, n, t) := \# \{ i ; d (f^i (x), f^i (y)) < t, 0 \leq i \leq n - 1 \},
$$

$$
\Phi_{xy} (t, f) := \liminf_{n \to \infty} \frac{1}{n} \xi_f (x, y, n, t),
$$

$$
\Phi^*_{xy} (t, f) := \limsup_{n \to \infty} \frac{1}{n} \xi_f (x, y, n, t),
$$

where as usual $\#A$ denotes the cardinality of a set $A$. If the map $f$ is clear from the context, we simply write $\Phi_{xy}(t)$ and $\Phi^*_{xy}(t)$.

Definition 1. If a pair of points $x, y \in X$ fulfills one of the following conditions:

- (DC1) $\Phi^*_{xy}(t) = 1$ for all $t > 0$ and $\Phi_{xy}(s) = 0$ for some $s > 0$,
- (DC2) $\Phi^*_{xy}(t) = 1$ for all $t > 0$ and $\Phi_{xy}(s) < 1$ for some $s > 0$,
- (DC3) $\Phi^*_{xy}(t) > \Phi_{xy}(t)$ for all $t \in J$, where $J$ is some nondegenerate interval,

then we say that $(x, y)$ is a DC1, DC2, or DC3 pair, respectively.

In recent years many authors were interested in systems with DC pairs. While there are numerous results on properties of DC1 and DC2 pairs, not many are known about systems with only DC3 pairs. The reason is that if a DC3 pair can be detected, then there usually also exist DC2 pairs in the system.

By the definition we immediately have that DC1 implies DC2 and DC2 implies DC3, and it is also known that none of the reverse implications holds (e.g., see [4]). It can also be proved that DC1 or DC2 implies chaos in the sense of Li and Yorke, but DC3 does not [5]. Furthermore, recent result of Downarowicz shows that positive topological entropy is a sufficient condition for large set of DC2 pairs (so-called...
scrambled set of type 2) in the system [6]. In [7, 8] the
author shows that strong mixing properties, for example,
specification property or topological exactness, are sufficient
for scrambled sets of type 1. In [5] there is an example
distal map with DC3 pairs; hence, DC3 does not imply
positive topological entropy or Li-Yorke pairs. Moreover, DC1
need not imply positive topological entropy, even in minimal
systems (e.g., see [9]).

In this paper, we investigate the relationship between DC3
pairs and the set of discontinuities in distribution function.
This will highlight many problems which can arise when one
looks for numerical evidence of distributional chaos.

2. Distributional Chaos of Type 3

In this section we will focus on properties of distribution
functions \( \Phi_{xy} \) and \( \Phi^*_{xy} \), which may cause many problems
during numerical investigation of the dynamics.

2.1. Discontinuity Points. The essential ingredient of all the
three definitions of DC pairs is “sufficiently large” difference
in values of functions \( \Phi_{xy} \) and \( \Phi^*_{xy} \). Accordingly, an
important question is how much values of \( \Phi_{xy} \) and \( \Phi^*_{xy} \) can differ if
\( x, y \) is not a DC3 pair. The following observation provides an
upper bound.

Proposition 2 (see Lemma 1 of [10]). The following conditions
are equivalent:

1. \( (x, y) \) is not a DC3 pair;
2. the set
\[
U_{xy} = \left\{ t; \Phi_{xy}(t) \neq \Phi^*_{xy}(t) \right\}
\]

is at most countable.

Proof. Implication (2) \( \Rightarrow \) (1) is trivial.
Conversely, assume that \( (x, y) \) is not DC3 pair. Let \( D_1, D_2 \)
be the set of discontinuity points of \( \Phi_{xy} \) and \( \Phi^*_{xy} \), respectively.
If \( s \notin D_1 \cup D_2 \), then \( \Phi_{xy}(s) = \Phi^*_{xy}(s) \), because otherwise they
would be different on an open interval containing \( s \). Since
both functions \( \Phi_{xy}, \Phi^*_{xy} \) are nondecreasing, they can have at
most countably many discontinuity points, which ends the
proof.

As we see, that \( \Phi_{xy}(t) \neq \Phi^*_{xy}(t) \) for some values of param-
eter \( t \) need not be enough for the occurrence of DC3 pair. If
we try to predict distributional chaos numerically, then the
parameter value we consider may be a discontinuity point of
function \( \Phi_{xy}(t) \) or \( \Phi^*_{xy}(t) \), and the pair is not DC3. Then we
may think that the system has DC3 pairs while it does not.
Therefore, to ensure ourselves that considered pair is DC3, we
can pick another parameter value and repeat simulation. But
again it can be another discontinuity point, and so on. From
one point of view the set of such discontinuity points is small
(it has Lebesgue measure zero), so in perfect situation the
chance of picking up such a point is zero. However, if the set
of discontinuity points may coincide with, say, \((a, b) \cap \mathbb{Q} \) for
some \( a < b \), then all the points in \((a, b) \) that can be considered
for computer simulation are wrong. So the first question is
whether there really is a risk of such situation.

For any set \( A \), we denote its characteristic function by \( \chi_A \).

Theorem 3. For any \( t \in (0,1) \) there is a map \( f \in C([0,1]) \)
without DC3 pairs and two points \( x, y \in [0,1] \) such that \( \Phi_{xy} = \chi_{\{t, t+\infty\}} \) and \( \Phi^*_{xy} = \chi_{\{t, t+\infty\}} \).

Proof. Fix any increasing sequence \( n_i > 0 \) such that
\( \lim_{i \to \infty} (n_i/n_{i+1}) = 0 \). Let \( \delta_i \) be a decreasing sequence such
that \( 0 < \delta_i = \min \{1 - t, t\} \) for all \( i \geq 0 \). Now let \( x_j = \delta_j \) and
\( y_j = t + \delta_j - y_j \) where
\[
y_j = \begin{cases} \delta_j - \delta_{j+1}, & \text{if } j \in [n_{2k-1}, n_{2k}) \text{ for some } k \geq 1, \\ 0, & \text{otherwise.} \end{cases}
\]

Let \( f \) be the connect-the-dots map defined by the following
points; that is, \( f \) is linear on countably many intervals with
values at the endpoints of these intervals given by
\[
f(0) = 0, \quad f(t) = t, \quad f(1) = 1, \\
f(x_n) = x_{n+1}, \quad f(y_n) = y_{n+1}, \quad \forall n = 1, 2, \ldots.
\]

Then we see that for any \( x \in [0,1] \) its \( \omega \)-limit set is the
singleton consisting of one of the points \( 0, t, 1 \). Similarly we
can verify that \( \Omega(f) = [0,1,t] \) and so \( f \) has zero topolog-
ical entropy. Then it has no DC3 pair by [1].

Consider the pair \( (x, y) = (x_0, y_0) \). Then \( f^n(x)-f^n(y) =
\]
\[
\]
\[
\]
We can see that
\[
\xi_f(x, y, n, t) = \# \{ i; \gamma_i > 0, 0 \leq i \leq n-1 \}.
\]

Therefore we can easily verify that
\[
\frac{1}{n_{2k}} \xi_f(x, y, n_{2k}, t) \geq \frac{n_{2k} - n_{2k-1}}{n_{2k} \rightarrow 1}, \\
\frac{1}{n_{2k+1}} \xi_f(x, y, n_{2k+1}, t) \leq \frac{n_{2k}}{n_{2k+1}} \rightarrow 0.
\]

Thus \( \Phi_{xy}(t) = 1 \) and \( \Phi_{xy}(t) = 0 \). On the other hand, for any
\( \delta > 0 \) we have that \( t - \delta \leq |f^n(x) - f^n(y)| \leq t \), provided that
\( \delta \) is sufficiently large. This gives \( \Phi^*_{xy}(s) = \Phi_{xy}(s) = 0 \) for \( s < t \)
and \( \Phi^*_{xy}(s) = \Phi_{xy}(s) = 1 \) for \( s > t \).
the Sharkovsky ordering (see [3]). Then we know that this map has topological entropy zero (thus has no DC3 pair) and a cycle consisting of exactly $2^i$ elements contained in the interval $(0, 1)$. We may assume that $0$ is fixed points of $f$. We can also transform the interval $[0, 1]$ by a piecewise linear homeomorphism in such a way that points of our cycle coincide with the sequence $t_1 < \cdots < t_j$. In other words, without loss of generality we may assume that $t_1, \ldots, t_j$ form a cycle for $f$ (topological entropy is maintained by topological conjugacy). Observe that the set

$$Q = \{ x \in [0, 1]; f^k(x) = t_i \text{ for some } k \geq 0 \text{ and } 1 \leq i \leq k \}$$

is at most countable, since $f$ is piecewise linear. We can also embed intervals of sufficiently small diameters around points in $Q$ (so that the total sum of these diameters is finite), similarly as it is done in the case of the standard Donjoy extension for circle rotation [3]. Each of these intervals is transformed from one onto another with the order defined by $f$ on $Q$. Entropy remains unchanged (homeomorphism on the interval has topological entropy zero) and, hence, there is no DC3 pair for our modified map. But now we have a periodic sequence of intervals for $f$ which were embedded in place of periodic orbit $t_1, \ldots, t_j$, and we may also assume that points $t_i$ are in the interiors of these intervals (if not, we use piecewise linear homeomorphism once again). Without loss of generality we may assume that a small neighborhood of $0$ has an invariant neighborhood on which $f$ is a homeomorphism.

Now it is enough to repeat the trick used in Theorem 3 in each of the intervals defined by points $t_i$ and the neighborhood of $0$ to produce discontinuities of the functions $\Phi_{x}$ and $\Phi_{y}$, where $x$ is a point attracted by the cycle $t_1, \ldots, t_j$ and $y$ by the fixed point $0$. Obviously, we must prevent fluctuations of distance on intervals embedded around points $t_1, \ldots, t_j$ to have exactly $s$ points of discontinuity of $\Phi_{x}$ and $\Phi_{y}$. 

It seems that the ideas of Theorem 4 can be extended even further. If instead of cycle we take an adding machine acting on the Cantor set properly embedded in $(0, 1)$ and next arrange intervals along a dense orbit (exactly the same way as in Donjoy example [3]), then there is a hope that a pair with a countable set of discontinuities is constructed. In other words, it seems possible that the following question has a positive answer.

**Question 1.** Is there a map $f : [0, 1] \to [0, 1]$ with zero topological entropy which has a pair $(x, y)$ such that $U_{xy}$ is countable?

While no answer to the question raised earlier is provided, the following theorem shows that $U_{xy}$ can be countable for a pair which is not DC3.

**Theorem 5.** There is a map and a pair $(x, y)$ such that $(x, y)$ is not DC3 but $U_{xy}$ is infinite.

**Proof.** Put $\mathcal{Y} = [-1, 1]^n$ and endow it with the natural metric $d(x, y) = \sum_{i=0}^{\infty} |x_i - y_i|/2^i$. It is well known that the shift map $\sigma : \mathcal{Y} \to \mathcal{Y}$ given by $\sigma(x_i) = x_{i+1}$, $i = 1, 2, \ldots$, is continuous.

We are going to construct two special sequences $x, y \in \mathcal{Y}$. For $r \in [-1, 1]$ and $k \geq 1$ denote by $(r)^k$ the constant sequence $r, r, \ldots, r$ consisting of exactly $k$ elements and by $(r)^\infty$ the infinite constant sequence $r, r, \ldots$. If $u, w$ are sequences, then $uw$ denotes the concatenation of these two sequences, $(u)^k$ denotes the $k$-times concatenation of $u$ with itself, and $|u|$ denotes the length of $u$.

Put $s_n = 2^n \sum_{i=0}^{2^n-1} q_i$, $v_n = s_n n^{-1}$, $c_n = \sum_{i=0}^{2^n-1} q_i$ for $n \geq 1$, and

$$t_n^i = \begin{cases} 2^{2n-i-1}, & \text{if } 0 \leq i \leq n-1, \\ 2^n, & \text{if } i = n. \end{cases}$$

Denote that $\tilde{u}_n = (1/2)^{(n+1)/2} \cdots (1/2)^{n/2}$. Then $|\tilde{u}_n| = \sum_{i=0}^{n} t_n^i = l_n$. For $k = 0, \ldots, n$, denote that $\tilde{u}_n^k = (1/2)^{(n-k+1)/2} \cdots (1/2)^{k/2}$; then

$$|\tilde{u}_n^k| = \frac{\sum_{i=0}^{n-k} t_n^i}{l_n} = 1 \quad \text{for } k \geq 1.$$ 

We put $u_n = (\tilde{u}_n)^n$ for all $n \geq 1$, so in particular $|u_n| = q_n$. Let $x = u_1 u_2 \cdots$ and $y = (-1)^0 (1/2)^{y_1} \cdots (-1)^n (1/2)^{y_n} \cdots$. Let $X$ be the union of closure of orbits of $x$ and $y$. For $z \in \mathcal{Y}$ by $z[i, j]$ we denote the finite subsequence of $z$ formed by entries from $i$th to $j$th position, that is, if $z = z_1 z_2 \cdots$, then $z[i, j] = z_i z_{i+1} \cdots z_j$.

Note that $s_n = (s_{n-1})^2 > 2^{n-1} s_{n-1}$ and $l_n \geq l_{n-1}$; hence, $q_n \geq 2^{n-1} q_{n-1}$ and so

$$\lim_{n \to \infty} \frac{c_{n-1}}{q_n} \leq \lim_{n \to \infty} \frac{(n-1) q_{n-1}}{2^n q_{n-1}} = 0,$$

$$\lim_{n \to \infty} \frac{l_{n-1}}{q_n} = \frac{4}{\lim_{n \to \infty} s_n} = 0.$$}

Fix any $k \geq 0$ and any $m \geq n > k$. If $j > 0$ is an index such that $x[j + 1, j + m]$ is a subblock of $\tilde{u}_n$ of the form $(1/2)^k$, then by the structure of $x$ and $y$, we have that $y[j + 1, j + m]$ is a subblock of $(-1)^n (1/2^n)^k$. Assume that $j$ as abovementioned has been fixed. We have two possibilities.

**Case A.** $n$ is an even number. Then

$$d \left( \sigma^j(x), \sigma^j(y) \right) = \sum_{i=0}^{m} \frac{1/2^k - 1/2^n}{2^i} + \sum_{i=m+1}^{\infty} \frac{|x_{j+i} - y_{j+i}|}{2^i} \quad \text{(11)}$$

$$= a_n + \sum_{i=m+1}^{\infty} \frac{|x_{j+i} - y_{j+i}|}{2^i},$$
where
\[ a_n = \sum_{i=1}^{m} \left( \frac{1}{2^k} - \frac{1}{2^n} \right)^i \]
(12)
Thus
\[ a_n \leq \frac{1}{2} - \frac{1}{2^n} - \frac{1}{2^{k+m}} + \frac{1}{2^{m+n}}. \]
(13)
Since \( m > n \), we have \( d(\sigma^i(x), \sigma^i(y)) < 1/2^k \).

Case B. \( n \) is an odd number. Then
\[ d(\sigma^i(x), \sigma^i(y)) = \sum_{i=1}^{m} \left( \frac{1}{2^k} + \frac{1}{2^n} \right)^i \]
\[ + \sum_{i=m+1}^{\infty} \frac{|x_{j+i} - y_{j+i}|}{2^i} \]
\[ = b_n + \sum_{i=m+1}^{\infty} \frac{|x_{j+i} - y_{j+i}|}{2^i}, \]
where
\[ b_n = \sum_{i=1}^{m} \frac{1}{2^k} + \frac{1}{2^n} \]
(15)
Thus
\[ b_n \leq d(\sigma^i(x), \sigma^i(y)) \]
\[ \leq b_n + \sum_{i=m+1}^{\infty} \frac{1}{2^i} = b_n + \frac{1}{2^n}. \]
(16)
Since \( m > n > k > 0 \), we have \( d(\sigma^i(x), \sigma^i(y)) > 1/2^k \).

From Case A and Case B we can see that if \( k \) is fixed and \( n \) increases, then \( d(\sigma^i(x), \sigma^i(y)) \) tends to \( 2^{-k} \).

Thus, provided that \( x[j+1, j+m] \) lies in \( (1/2^k)^t \) of \( \tilde{u}_n \), the related \( n \) and \( m \) tend to \( \infty \) as \( j \to \infty \), and, hence,
\[ d(\sigma^i(x), \sigma^i(y)) \to \frac{1}{2^k} \] as \( j \to \infty \).
(17)

Now we are ready for the main proof. For any positive number \( l \geq q_2 \), we can write
\[ l = c_n + p l_{n+1} + r, \]
(18)
where \( p \geq 0 \), \( 0 \leq r < l_{n+1} \), and \( p l_{n+1} + r < q_{n+1} \) are uniquely determined. Thus
\[ x[1, l] = u_1 u_2 \cdots u_{n-1} (\tilde{u}_n)^{\nu} (\tilde{u}_{n+1})^{\nu}, \]
(19)
where \( \nu = x[c_n + p l_{n+1} + 1, c_n + p l_{n+1} + r] \).

Case I. Fix any \( t \in (1/2^k, 1/2^{k-1}) \), \( k \geq 1 \).

By (17), when \( l \) is large enough, we have that
(a) if \( c_{n-1} < j+1 < j+2n \leq c_n + pl_{n+1} \) and block \( x[j+1, j+2n] \) falls within \( \tilde{u}_n \) or \( \tilde{u}_{n+1} \), then \( d(\sigma^i(x), \sigma^i(y)) < t \),
(b) similarly, if \( c_{n-1} < j+1 < j+2n \leq c_n + pl_{n+1} \) and block \( x[j+1, j+2n] \) does not intersect blocks \( \tilde{u}_n \) and \( \tilde{u}_{n+1} \) in \( x \), then \( d(\sigma^i(x), \sigma^i(y)) > t \).

Let us denote that \( q_t(h, i) = \# \{ j ; d(\sigma^i(x), \sigma^i(y)) < t, h \leq j \leq i-1 \} \). Then, by (a) and (b) aforementioned, for \( l \) large enough, we have that

\[ s_n \left( \left| \tilde{u}_n \right| - 2n \right) + p \left( \left| \tilde{u}_{n+1} \right| - 2n \right) \]
\[ \leq g_t \left( c_{n-1} + 1, c_n + pl_{n+1} \right) \]
(20)
\[ \leq s_n \left( \left| \tilde{u}_n \right| + 2n \right) + p \left( \left| \tilde{u}_{n+1} \right| + 2n \right). \]

Additionally, if \( l \) increases, then \( n \) increases as well and, hence,
\[ \lim_{l \to \infty} \frac{2n (s_n + p)}{l} \leq \lim_{n \to \infty} \frac{2n (s_n + p)}{q_n + pl_{n+1}} \leq \lim_{n \to \infty} \frac{2n s_n + 2n}{q_n + pl_{n+1}} \]
(21)
\[ \leq \lim_{n \to \infty} \frac{2n l_n + 2n}{l_{n+1}} \leq 2 \lim_{n \to \infty} \frac{2n l_n}{2^{2n}} = 0. \]

Observe that
\[ g_t \left( c_{n-1} + 1, c_n + pl_{n+1} \right) \leq \xi_t(x, y, l, t) \]
\[ \leq c_{n-1} + g_t \left( c_{n-1} + 1, c_n + pl_{n+1} \right) + r, \]
(22)
Hence, by the previous calculations and (9), we see that
\[ \lim_{l \to \infty} \frac{1}{l} \xi_t(x, y, l, t) \]
\[ = \lim_{l \to \infty} \frac{g_t \left( c_{n-1} + 1, c_n + pl_{n+1} \right)}{l} \]
\[ = \lim_{l \to \infty} \frac{g_t \left( c_{n-1} + 1, c_n + pl_{n+1} \right)}{q_n + pl_{n+1}} \cdot \frac{q_n + pl_{n+1}}{l} \]
\[
\lim_{n \to \infty} \frac{q_n (c_{n-1} + 1, c_n + p l_{n+1})}{q_n + p l_{n+1}} \\
\cdot \lim_{l \to \infty} \frac{q_n + p l_{n+1}}{l} \\
= \lim_{n \to \infty} \frac{s_n \left(\frac{c_{n-1}^2}{a_n^2} + p \frac{c_{n-1}^k}{a_{n+1}^k}\right)}{s_n \left(\frac{c_{n-1}^2}{a_n^2} + p \frac{c_{n-1}^k}{a_{n+1}^k}\right)} \\
\cdot \lim_{l \to \infty} \left(1 - \frac{r + c_{n-1}}{l}\right) \\
= \frac{1}{2^k} \cdot \lim_{l \to \infty} \left(1 - \frac{r + c_{n-1}}{l}\right).
\]

But \((r + c_{n-1})/l < (l_{n+1} + c_{n-1})/q_n\) and so, finally, by (10) we obtain that
\[
\lim_{l \to \infty} \frac{1}{2^k} \xi(x, y, l, t) = \frac{1}{2^k}.
\]

In other words, we have just proved that \(\Phi^*_x(t) = \Phi_x(t) = 1/2^k\) for any \(t \in (1/2^k, 1/2^{k-1})\) and any \(k \geq 1\).

It is not hard to verify that \(\Phi^*_x(t) = \Phi_x(t) = 1\) for every \(t \in (1, \infty)\).

**Case II.** It remains to analyze the situation when \(t = 1/2^k\) for some \(k \geq 0\). To estimate values of functions \(\Phi_x(t)\) and \(\Phi^*_x(t)\), let us consider the particular case of \(l = c_n\); that is, \(p = r = 0\) in (18).

**Case C.** Let \(n = 2s\) be an even number. By (17) and the previous discussion of Case A with \(m = 2n\), if \(l = c_2\) is large enough, then
\[
(a') \text{ if } c_{n-1} < j + 1 < j + 2n \leq c_n \text{ and } x[j + 1, j + 2n] \text{ lies within some } \bar{u}_n^k, \text{ then } d(\sigma(x), \sigma(y)) < t; \\
(b') \text{ if } c_{n-1} < j + 1 < j + 2n \leq c_n \text{ and } x[j + 1, j + 2n] \text{ does not intersect block } \bar{u}_n^k, \text{ then } d(\sigma(x), \sigma(y)) > t.
\]

Thus performing calculations similar to these done in Case I leads to the following:
\[
\lim_{l \to \infty} \frac{1}{2^k} \xi(x, y, 2s, t) = \frac{1}{2^k}.
\]

**Case D.** Let \(n = 2s + 1\) be an odd number. By (17) and the discussion in Case B, we have that when \(l = c_{2s+1}\) is large enough then
\[
(a'') \text{ if } c_{n-1} < j + 1 < j + 2n \leq c_n \text{ and } x[j + 1, j + 2n] \text{ is a subblock of some } \bar{u}_n^k, \text{ then } d(\sigma(x), \sigma(y)) < t; \\
(b'') \text{ if } c_{n-1} < j + 1 < j + 2n \leq c_n \text{ and } x[j + 1, j + 2n] \text{ does not intersect block } \bar{u}_n^k, \text{ then } d(\sigma(x), \sigma(y)) > t.
\]

Again, repeating calculations similar to these in Case I, we see that
\[
\lim_{l \to \infty} \frac{1}{2^k} \xi(x, y, 2s+1, t) = \frac{1}{2^k}.
\]

Combining Cases C and D, we obtain that \(\Phi^*_x(t) \geq 1/2^k > 1/2^{k+1} \geq \Phi_x(t)\), provided that \(t = 1/2^k\) for some \(k \geq 0\). Summing up Cases I and II together, we see that \(U_x = \{1/2^k; k = 0, 1, 2, \ldots\}\), which completes the proof.

**Corollary 6.** Let \((X, \sigma)\) be the dynamical system defined in Theorem 5. Then it has no DC3 pair.

**Proof.** We can easily obtain from Theorem 5 that \(U_{x,y} = \{1/2^k; k = 0, 1, 2, \ldots\}\) when \(x_1 = \sigma^t(x)\) and \(y_1 = \sigma^t(y)\) for some \(l, s \geq 0\), since
\[
\lim_{n \to \infty} \frac{1}{2^k} \# \{i; x_{i+1} \neq x_{i}, 0 \leq i < n\} \\
= \lim_{n \to \infty} \frac{1}{2^k} \# \{i; y_{i+1} \neq y_{i}, 0 \leq i < n\} = 0.
\]

Observe that
\[
\omega(x, \sigma) = \left\{ \left\{ \frac{1}{2^n}, \left\{ \frac{1}{2^n+1}, k \geq 0 \right\} \right\} \cup \left\{ \left\{ 0 \right\}, k \geq 0 \right\}, \omega(y, \sigma) = \left\{ \left\{ 0 \right\} \right\}.
\]

Hence for any \(x_1, y_1 \in X\), we have the following:
\[
U_{x,y} = \left\{ \begin{array}{ll}
\left\{ \frac{1}{2^n}, k = 0, 1, 2, \ldots \right\}, & \text{if } x_1 \in \text{Orb}_x(x), \ y_1 \in \text{Orb}_y(y), \\
\emptyset, & \text{if } x_1, y_1 \in \text{Orb}_o(x), \emptyset, & \text{if } x_1, y_1 \in \text{Orb}_o(y), \\
\emptyset, & \text{if } x_1 \in \text{Orb}_o(x), \ y_1 \in \omega(y, \sigma), \\
\left\{ \left\{ \frac{1}{2^n} \right\} \right\} & \text{for one } k \geq 0, \text{ if } x_1 \in \omega(x, \sigma), \ y_1 \in \text{Orb}_o(y) .
\end{array} \right.
\]

Each case is either trivial or has very similar proof which follows directly from Theorem 5 and (27).

2.2. **Higher Iterates.** It is well known that DC1 or DC2 pairs are preserved by higher iterates; that is, DC1 (or DC2) pair for \(f\) is also DC1 (resp., DC2) pair for \(f^n\) for every \(n \geq 1\) and vice versa. In this section we will show that there is no such correspondence in the case of DC3 pair.

**Theorem 7** (see Theorem 1 of [10]). If \((x, y)\) is a DC3 pair of \(f\), then for every \(n > 0\) there is \(0 \leq r < n\) such that \((f^r(x), f^r(y))\) is DC3 for \(f^n\).

**Proof.** Let \((x, y)\) be a DC3 pair for \(f\), and let \(J\) be an open interval such that \(\Phi_{xy}(t, f) < \Phi^*_x(t, f)\) for every \(t \in J\). There is \(s \in J\) such that each function \(\Phi_{f^i(x), f^i(y)}(\cdot, f^n)\), \(\Phi^*_f(x), f^i(y)(\cdot, f^n), i = 0, 1, \ldots, n-1\), is continuous at \(s\).
Observe first that if we denote that \( l = kn + r \), for some \( 0 \leq r < n \) and \( k \geq 0 \) (here \( k \), \( r \) depend on \( l \); i.e., \( k = k(l) \), \( r = r(l) \)), then

\[
\sum_{i=0}^{n-1} \xi_f\left(f^i(x), f^i(y), k, t\right) \\
\leq \xi_f(x, y, l, t) \leq \sum_{i=0}^{n-1} \xi_f\left(f^i(x), f^i(y), k + 1, t\right).
\]

This immediately implies that

\[
\sum_{i=0}^{n-1} \Phi_{f^i(x)f^i(y)}(t) \\
= \sum_{i=0}^{n-1} \lim_{k \to \infty} \frac{1}{k} \xi_f\left(f^i(x), f^i(y), k, t\right) \\
\leq n \lim_{l \to \infty} \frac{1}{nk(l)} \\
\times \sum_{i=0}^{n-1} \xi_f\left(f^i(x), f^i(y), k, l, t\right) \\
= n \lim_{l \to \infty} \frac{1}{l} \sum_{i=0}^{n-1} \xi_f\left(f^i(x), f^i(y), k, l, t\right) \\
\leq n \lim_{l \to \infty} \frac{1}{l} \xi_f(x, y, l, t) = n\Phi_{xy}(t).
\]  

(31)

Similar calculations lead to the following:

\[
\sum_{i=0}^{n-1} \Phi_{f^i(x)f^i(y)}(t) \geq n\Phi_{xy}(t).
\]  

(32)

Now, if none of pairs \( (f^i(x), f^i(y)) \) is DC3, then \( \Phi_{f^i(x)f^i(y)}(s) = \Phi_{f^i(x)f^i(y)}(s) \) for \( i = 0, 1, \ldots, n-1 \), and, hence, \( \Phi_{xy}(s) = \Phi_{xy}(s) \), which is a contradiction. \( \square \)

Define a sequence \( x_n = (1/(n+1), t_n) \in \mathbb{R}^2 \) by putting \( t_0 = t_2 = 1/4 \),

\[
t_{2i} = \begin{cases} 
\frac{1}{4} + \frac{i - s_{2i+1}}{2(2k + 1)}, & \text{if } s_{2i+1} \leq i < s_{2i+1} + (2k + 1), \\
\frac{3}{4}, & \text{if } s_{2i+1} + (2k + 1) \leq i < s_{2i+2}, \\
\frac{3}{4} - \frac{i - s_{2i+2}}{2(2k + 2)}, & \text{if } s_{2i+2} \leq i < s_{2i+2} + (2k + 2), \\
\frac{1}{4}, & \text{if } s_{2i+2} + (2k + 2) \leq i < s_{2i+3},
\end{cases}
\]  

(34)

for \( k \geq 0 \), and \( t_{2i+1} = t_{2i} - 1 \) for \( i \geq 0 \). Next put \( y_n = (1/(n+1), 0) \) for \( n \geq 0 \). Finally \( X = \{x_n, y_n; n \geq 0\} \).

We define \( f : X \to X \) by putting \( f(x_n) = x_{n+1} \), \( f(y_n) = y_{n+1} \), \( f((0,0)) = 0 \), \( f((0, t)) = (0, t - 1) \) for \( t \in [1/4, 3/4] \) and \( f((0, t)) = (0, t + 1) \) for \( t \in [-3/4, -1/4] \).

Since \( \lim_{n \to \infty} d(x_n, x_{n+1}) = 0 \), it is easy to verify that \( f \) is continuous.

Put \( x = x_0 \) and \( y = y_0 \). By (33) and comparing \( d(f^{i+1}(x), f^{i+1}(y)) \) with \( d(f^i(x), f^i(y)) \), we have that

\[
\lim_{n \to \infty} \frac{1}{n} \# \left\{ i ; d \left( f^i(x), f^i(y) \right) = \frac{1}{4}, 0 \leq i \leq n-1 \right\} \\
= \lim_{n \to \infty} \frac{1}{n} \# \left\{ i ; d \left( f^i(x), f^i(y) \right) = \frac{3}{4}, 0 \leq i \leq n-1 \right\} \\
= \frac{1}{2}.
\]  

(35)

Thus \( \Phi_{xy}(t, f) = \Phi_{xy}(t, f) \) for all \( t > 0 \). That is to say, \((x, y)\) is not a DC3 pair for \( f \).

On the other hand, \( d(f^{i+1}(x), f^{i+1}(y)) = t_{2i} \) for all \( i \geq 0 \); hence, by (33) we have that

\[
\lim_{k \to \infty} \frac{1}{s_{2k+1}} \# \left\{ i ; d \left( \left( f^i \right)^{(1)}(x), \left( f^i \right)^{(1)}(y) \right) = \frac{3}{4}, 0 \leq i \leq s_{2k} - 1 \right\} \\
= \lim_{k \to \infty} \frac{1}{s_{2k+1}} \# \left\{ i ; d \left( \left( f^i \right)^{(1)}(x), \left( f^i \right)^{(1)}(y) \right) = \frac{1}{4}, 0 \leq i \leq s_{2k+1} - 1 \right\} \\
= 1.
\]  

(36)

Therefore \( \Phi_{xy}(t, f^2) = 1 \) and \( \Phi_{xy}(t, f^2) = 0 \) for every \( t \in (1/4, 3/4) \). In other words, we have just proved that \((x, y)\) is a DC3 pair for \( f^2 \), and so the proof is completed. \( \square \)

Remark 9. In [10] there is another example of \( f \) with such property as in Theorem 8. But the example here is more simple and has zero topological entropy.

**Theorem 10.** There is a map \( f \) and a pair \((x, y)\) such that \((x, y)\) is DC3 for \( f^2 \) but not DC3 for \( f \).
Proof. Let \( x_n, y_n \) be the sequences defined in Theorem 8 with the only difference that now \( d(p, q) = 1/4 + |p_1 - q_1| \) if \( p \in \mathbb{R} \times [-\infty, 0] \) and \( q \in \mathbb{R} \times [1/4, +\infty] \), where \( p_1, q_1 \) denote first coordinates of respective points. We keep \( d \) as Euclidean distance for all other points. Now, if we consider \( x, y \) as in Theorem 8, then distance between their orbits under \( f^2 \) is equal to \( 1/4 \) for any iterate of \( f^2 \), while \( \Phi^*_xy(t, f) = 1 \), \( \Phi_{xy}(t, f) = 1/2 \) for every \( t \in (1/4, 3/4) \).

\[ \square \]
