We study the local and global bifurcation of nonnegative nonconstant solutions of a discrete general Brusselator model. We generalize the linear \( u \) in the standard Brusselator model to the nonlinear \( f(u) \). Assume that \( f \in C([0, \infty), [0, \infty)) \) is a strictly increasing function, and \( f'(f^{-1}(a)) \in (0, \infty) \). Taking \( b \) as the bifurcation parameter, we obtain that the solution set of the problem constitutes a constant solution curve and a nonconstant solution curve in a small neighborhood of the bifurcation point \((b_0, f^{-1}(a), ab/[f^{-1}(a)]^2)\). Moreover, via the Rabinowitz bifurcation theorem, we obtain the global structure of the set of nonconstant solutions under the condition that \( f(s)/s^2 \) is nonincreasing in \((0, \infty)\). In this process, we also make a priori estimation for the nonnegative nonconstant solutions of the problem.

1. Introduction

In 1968, Prigogine and Lefever [1] introduced first the Brusselator model for a chemical reaction-diffusion of self-catalysis as follows:

\[
\begin{align*}
\frac{\partial u}{\partial t} - d_1 \Delta u &= a - (b + 1)u + u^2v, \quad x \in \Omega, t > 0, \\
\frac{\partial v}{\partial t} - d_2 \Delta v &= bu - u^2v, \quad x \in \Omega, t > 0, \\
\frac{\partial u}{\partial n} = \frac{\partial v}{\partial n} &= 0, \quad x \in \partial \Omega, t > 0,
\end{align*}
\]

where \( \Omega \subset \mathbb{R}^N (N \geq 1) \) is a smooth and bounded domain, \( n \) denotes the outward unit normal vector on \( \partial \Omega \), \( u \) and \( v \) represent the concentration of two intermediary reactants having the diffusion rates \( d_1, d_2 \in (0, \infty) \) with \( d_2 > d_1 \), and \( a, b > 0 \) are the fixed concentrations. This chemical reaction plays an important role due to its similarities with neuronal and biological networks. Therefore, (1) has been extensively investigated in the last decades from both analytical and numerical point of view (see [2–12]). Most of them are interested in finding spatially nonconstant solutions of the equilibrium problem

\[
\begin{align*}
-d_1 \Delta u &= a - (b + 1)u + u^2v, \quad x \in \Omega, \\
-d_2 \Delta v &= bu - u^2v, \quad x \in \Omega, \\
\frac{\partial u}{\partial n} = \frac{\partial v}{\partial n} &= 0, \quad x \in \partial \Omega.
\end{align*}
\]

From the definition of Strogatz [13], chaos sensitivity depends on initial conditions, which shows that nearby trajectories diverge exponentially. Continuous systems in a 2-dimensional phase space cannot experience such divergence; hence, chaotic behaviors can only be observed in deterministic continuous systems with a phase space of dimension 3, at least. On the contrary, in a discrete map, it is well known that chaos occurs also in one dimension. Therefore, discrete chaotic systems exhibit chaos whatever their dimension is.

It is worth to note that discrete models governed by difference equations are more appropriate than the
where 0 < h < 1 represents the step size for Euler’s method. The local dynamical behaviors are obtained for (3).

Note that [16–18] only studied the dynamical behaviors of the discrete-time Brusselator model. The reason is that the partial difference equation is very difficult for us. Indeed, the discrete-space Brusselator model is also worth studying due to the discontinuity of the space.

Therefore, we will consider the discrete space, more general form of (2) with N = 1:

\[
\begin{align*}
-d_1 \Delta^2 u(x - 1) &= a - (b + 1)f(u(x)) + u^2(x)v(x), & x \in \mathbb{T}, \\
-d_2 \Delta^2 v(x - 1) &= b f(u(x)) - u^2(x)v(x), & x \in \mathbb{T}, \\
\Delta u(0) &= \Delta u(T) = \Delta v(0) = \Delta v(T) = 0,
\end{align*}
\]

where \( \Delta u(x) = u(x + 1) - u(x), \mathbb{T} = [1, T] = \{1, 2, \ldots, T\}, T \geq 2 \) is an integer, \( d_1, d_2, a > 0 \) are fixed parameters and \( d_2 > d_1, b > 0 \) is a bifurcation parameter. Clearly, \( f(u) = (f(u)/u) \cdot u \); then, (4) is seen to be equivalent to

\[
\begin{align*}
-d_1 \Delta^2 u(x - 1) &= a - (b + 1)f(u(x)) \cdot \frac{u(x)}{u(x)} + u^2(x)v(x), & x \in \mathbb{T}, \\
-d_2 \Delta^2 v(x - 1) &= b \frac{f(u(x))}{u(x)} \cdot u(x) - u^2(x)v(x), & x \in \mathbb{T}, \\
\Delta u(0) &= \Delta u(T) = \Delta v(0) = \Delta v(T) = 0,
\end{align*}
\]

where \( f(u)/u \) can be regarded as a variable coefficient. It is well known that the linear terms \((b + 1)u\) and \( bu \) in (2) cannot withstand any small perturbation.

In fact, (5) has an important application value in biology and chemistry. Xu et al. [19] said that model (1) includes a basic assumption: the cells always live in a continuous patch environment. However, this may not be the case in reality, and the motion of individuals of given cells is random and isotropic, i.e., without any preferred direction, the cells are also absolute individuals. The cells or units are also absolute individuals in microscopic sense, and each isolated cell exchanges materials by diffusion with its neighbors. Thus, it is reasonable to consider a 1D or 2D spatially discrete reaction-diffusion system in order to explain the chemical system.

Kang [20] discussed the dynamics of the local map of a discrete version of the Brusselator model. To discretize system (1), he employed the following discretizations:

For the derivative in time, he used

\[
\frac{\partial u(x, t)}{\partial t} \rightarrow \frac{u(x, t + \Delta t) - u(x, t)}{\Delta t}, \quad (6)
\]

For the space derivative, he used

\[
\frac{\partial u(x, t)}{\partial x} \rightarrow \frac{u(x + \Delta x, t) - u(x, t)}{\Delta x}, \quad (7)
\]

\[
\frac{\partial^2 u(x, t)}{\partial x^2} \rightarrow \frac{u(x + \Delta x, t) - 2u(x, t) + u(x - \Delta x, t)}{(\Delta x)^2}, \quad (8)
\]

It is important to note that \( \Delta \) in (6)–(8) is different from \( \Delta \) in this paper. Our discretization is consistent with Kang’s, and we chose the step size to be 1. When \( f(u) = u \), (5) is the steady-state form of the problem studied in [19, 20].

On the contrary, the Brusselator system has been investigated from the numerical point of view (see [21] and references therein). Most modern texts on numerical analysis give an introduction to numerical solutions of partial differential equations using the finite-difference approach. Twizell et al. [22] had given a second-order finite-difference scheme for the Brusselator reaction-diffusion system. It is well known that (2) is an important mathematical dynamics model in biology and chemistry. In some ways, (5) is even more practical than (2).
We will study the local and global bifurcation of non-negative nonconstant solutions of (4) under the following assumptions:

(H1) \( f \in C([0, \infty), [0, \infty)) \) is a strictly increasing function
(H2) \( f'(f^{-1}(a)) \in (0, \infty) \)
(H3) \( f(s)/s^2 \) is nonincreasing in \( (0, \infty) \)

Remark 1. If \( f(u) = u \), then (4) is the discrete version of (2) with \( N = 1 \). Obviously, discrete Brusselator model (4) is a second-order difference boundary value problem.

The rest of the paper is organized as follows: in Section 2, we give a priori estimate and some preliminary results. Section 3 is devoted to studying the local bifurcation of non-negative nonconstant solutions of (4) under conditions (H1) and (H2). Finally, in Section 4, we add condition (H3) to obtain the global bifurcation of nonnegative nonconstant solutions of (4).

2. Preliminary Results

At first, let us look for the constant solution of (4). To get it, it suffices to look for the constant solution of the following problem:

\[
\begin{align*}
\frac{d}{dt}(u(t)) & = a - (b + 1)f(u(t)) + u^2(t)v(t), \\
\frac{d}{dt}(v(t)) & = b f(u(t)) - u^2(t)v(t),
\end{align*}
\]

By (H1), problem (4) has a unique constant solution \( f^{-1}(a), ab/[f^{-1}(a)]^2 \).

We can easily obtain the following a priori estimate of the nonnegative nonconstant solutions of (4).

Lemma 1. Let (H1), (H2), and (H3) hold. Then, any nonnegative nonconstant solution \( (u, v) \) of (4) satisfies

\[
f^{-1}(\frac{a}{b+1}) \leq u(x) \leq f^{-1}(a) + \frac{d_1}{d_1} \cdot \frac{ab}{b+1} \cdot \frac{1}{[f^{-1}(a/(b+1))]^2}, \quad x \in \mathbb{T},
\]

Then,

\[
v(x) \leq v(x_1) \leq \frac{bf(u(x_1))}{u^2(x_1)}, \quad x \in \mathbb{T}.
\]

Combining this with (13), from (H3), we show

\[
v(x) \leq \frac{bf(u(x_1))}{u^2(x_1)} \leq \frac{ab}{(b+1)[f^{-1}(a/(b+1))]^2}, \quad x \in \mathbb{T}.
\]

Let \( w = d_1u + d_2v \). Then, it follows from (4) that

\[
\begin{align*}
\Delta^2 w(x-1) & = a - f(u(x)), \quad x \in \mathbb{T}, \\
\Delta w(0) & = \Delta w(T) = 0.
\end{align*}
\]

Now, let \( x_2 \in \mathbb{T} \) be the maximum point of \( w \). Observe that

\[
\begin{align*}
w(x_2 + 1) & \geq w(x_2), \\
w(x_2 - 1) & \geq w(x_2), \\
-\Delta^2 w(x_2 - 1) & = a - f(u(x_2)) \geq 0.
\end{align*}
\]

Then, from (H1), it is easy to see \( u(x_2) \leq f^{-1}(a) \).

Combining this with (17), we know that, for any \( x \in \mathbb{T} \),

\[
d_1u(x) \leq w(x) \leq w(x_2) \leq d_1f^{-1}(a) + d_2\frac{ab}{(b+1)[f^{-1}(a/(b+1))]^2}.
\]

Proof. Let \( x_0 \in \mathbb{T} \) be the minimum point of \( u \). We have

\[
\begin{align*}
u(x_0 + 1) & \geq u(x_0), \\
u(x_0 - 1) & \geq u(x_0), \\
-d_1\Delta u(x_0 - 1) & = -d_1\left( u(x_0 - 1) + 2u(x_0) + u(x_0 - 1) \right) \leq 0.
\end{align*}
\]

Then,

\[
a - (b + 1)f(u(x_0)) + u^2(x_0)v(x_0) \leq 0,
\]

\[
\begin{align*}
a - (b + 1)f(u(x_0)) & \leq 0, \\
f(u(x_0)) & \geq \frac{a}{b+1}.
\end{align*}
\]

Then, \( u(x) \geq f^{-1}(a/(b+1)) \) by (H1), and so

\[
u(x) \geq u(x_0) \geq f^{-1}\left(\frac{a}{b+1}\right), \quad x \in \mathbb{T}.
\]

Let \( x_1 \in \mathbb{T} \) be the maximum point of \( v \). Similarly, we can get that

\[
\begin{align*}
v(x_1 + 1) & \leq v(x_1), v(x_1 - 1) \leq v(x), \\
-d_1\Delta v(x_1 - 1) & = -d_1\left( v(x_1 + 1) + 2v(x_1) + v(x_1 - 1) \right) \geq 0,
\end{align*}
\]

\[
bf(u(x_1)) - u^2(x_1)v(x_1) \geq 0.
\]
Then,
\[ u(x) \leq f^{-1}(a) + \frac{d_2}{d_1} \cdot \frac{a b}{(b+1)[f^{-1}(a/(b+1))]^2}, \quad x \in \mathbb{T}. \] (21)

Consequently, the proof is completed.

**Lemma 2** (see [23]). Assume \( T \geq 2 \) is an integer. Then, the discrete second-order linear Neumann eigenvalue problem
\[
\begin{align*}
-\Delta^2 \varphi(x-1) &= \mu \varphi(x), \quad x \in \mathbb{T}, \\
\Delta \varphi(0) &= \Delta \varphi(T) = 0,
\end{align*}
\] (24)
has \( T \) real and simple eigenvalues, which can be ordered as follows:
\[ 0 = \mu_0 < \mu_1 < \mu_2 < \cdots < \mu_{T-1}. \] (25)

Moreover, for \( j \in \{1, \ldots, T-1\} \), the eigenfunction \( \varphi_j \) corresponding to the eigenvalue \( \mu_j \) has exactly \( j - 1 \) simple generalized zeros.

For any fixed \( T \geq 2 \), it is well known that
\[ \mu_j = \begin{cases} 0, & j = 0, \\ 2 - \cos \left( \frac{j \pi}{T} \right), & j \in (1, T-1]. \end{cases} \] (26)

If \( x_3 \in \mathbb{T} \) is the minimum point of \( v \), then
\[ b f(u(x_3)) - u'(x_3)v(x_3) \leq 0, \] (22)
and so
\[ v(x) \geq v(x_3) \geq \frac{b f(u(x_3))}{u'(x_3)} \geq \frac{b f(f^{-1}(a) + (d_2/d_1) \cdot ab/(b+1)[f^{-1}(a/(b+1))]^2)}{[f^{-1}(a) + (d_2/d_1) \cdot ab/(b+1)[f^{-1}(a/(b+1))]^2]^2}, \quad x \in \mathbb{T}. \] (23)

and the corresponding eigenfunctions are
\[ \varphi_j(x) = \begin{cases} 1, & j = 0, \\
\cos \left( \frac{j \pi}{T} x \right), & j \in (1, T-1]. \end{cases} \] (27)

**Lemma 3** (see [18], Theorem 2.5). Let \( a \) be a constant. Then, for \( \Delta C(i) = 0 \),
\[ \sum_{i \in [a]} \cos ai = \frac{\sin a(i - (1/2))}{\sin (a/2)} + C(i), \quad (a \neq 2mn). \] (28)

**Lemma 4** (see [18], Theorem 2.7). If \( z_n \) is an indefinite sum of \( y_m \), then
\[ \sum_{k=m}^{n-1} y_k = [z_k]_m = z_n - z_m. \] (29)

Let
\[ X = \{(u, v) \mid u, v: \mathbb{T} \to \mathbb{R}, \Delta u(0) = \Delta u(T) = \Delta v(0) = \Delta v(T) = 0\}, \]
\[ X_1 = \{u: \mathbb{T} \to \mathbb{R}\}, \quad Y = X_1 \times X_1, \]
\[ (w_1, w_2)_Y = \sum_{x=1}^{T} u_1(x)u_2(x) + \sum_{x=1}^{T} v_1(x)v_2(x), \] (30)

where \( w_1 = (u_1, v_1), w_2 = (u_2, v_2) \in Y \) and \( \mathbb{T} := [0, T+1]. \)

### 3. Local Bifurcation

By the second part, \( \bar{w} := (f^{-1}(a), ab/[f^{-1}(a)]^2) \) is the unique constant solution of (4).

Define the mapping \( P: (0, \infty) \times X \to Y \):
\[ P(b, u) = \begin{pmatrix} d_1 \Delta^2 u(x-1) + a - (b+1)f(u(x)) + u^2(x)v(x) \\ d_2 \Delta^2 v(x-1) + b f(u(x)) - u^2(x)v(x) \end{pmatrix}. \] (31)

For the fixed \( b > 0, w = (u, v) \) is a solution of (4) if and only if \( (b, u) \) is a zero-point of \( P \). Note that \( P(b, \bar{w}) = \begin{pmatrix} 0 \\ 0 \end{pmatrix} \) since \( \bar{w} \) is the constant solution of (4).

Let
\[ u = f^{-1}(a) + \sum_{k=1}^{\infty} \varepsilon^k u_k, \]
\[ v = \frac{ab}{[f^{-1}(a)]^2} + \sum_{k=1}^{\infty} \varepsilon^k v_k, \]
\[ b = b_0 + \sum_{k=1}^{\infty} \varepsilon^k b_k. \] (32)

We also have to Taylor expand \( f \) at the point \( f^{-1}(a) \).

The purpose of the rest of this section is to solve \( b_0 \) and prove that \( (b_0, \bar{w}) \) is the bifurcation point of \( P(b, u) = \begin{pmatrix} 0 \\ 0 \end{pmatrix} \).
First of all, we substitute (32) and (33) into (4) and let the higher-order term of $\varepsilon$ be equal to 0. Then, we can get the problem

\[
\begin{aligned}
-d_1\Delta^2 u_1(x-1) &= \left(-b_0 f'(f^{-1}(a)) - f'(f^{-1}(a)) + \frac{2ab_0}{f^{-1}(a)}\right)u_1(x) + [f^{-1}(a)]^2 v_1(x), \quad x \in \mathbb{T}, \\
-d_2\Delta^2 v_1(x-1) &= \left(b_0 f'(f^{-1}(a)) - \frac{2ab_0}{f^{-1}(a)}\right)u_1(x) - [f^{-1}(a)]^2 v_1(x), \quad x \in \mathbb{T}, \\
\Delta u_1(0) &= \Delta u_1(T) = \Delta v_1(0) = \Delta v_1(T) = 0.
\end{aligned}
\tag{34}
\]

In (34), by using undetermined coefficient method, it follows that

\[
b_0 = \frac{f^{-1}(a)\left[d_1 d_2 \mu_j^2 + d_2 f'(f^{-1}(a)) \mu_j + d_1 \left[f^{-1}(a)\right]^2 \mu_j + \left[f^{-1}(a)\right]^2 f'(f^{-1}(a))\right]}{2ad_2 \mu_j - d_2 f^{-1}(a)f'(f^{-1}(a)) \mu_j} = b_0^j, \quad j = 1, 2, \ldots, T - 1.
\tag{35}
\]

Moreover, it is not difficult to prove (34) has a nontrivial solution $(u_1, v_1)$:

\[
\begin{aligned}
u_1 &= \cos\left(\frac{j\pi}{T}x\right) = \varphi_j(x), \\
c_1(j) &= -\frac{d_2 \mu_j}{d_1 \mu_j + f'(f^{-1}(a))}.
\end{aligned}
\tag{36}
\]

Next, we substitute (32) and (33) into (4) and let the higher-order term of $\varepsilon^2$ be equal to 0; then, (4) becomes the following system:

\[
\begin{aligned}
d_1\Delta^2 u_2(x-1) + \left(-b_0 f'(f^{-1}(a)) - f'(f^{-1}(a)) + \frac{2ab_0}{f^{-1}(a)}\right)u_2(x) + [f^{-1}(a)]^2 v_2(x) &= -F_1, \quad x \in \mathbb{T}, \\
d_2\Delta^2 v_2(x-1) + \left(b_0 f'(f^{-1}(a)) - \frac{2ab_0}{f^{-1}(a)}\right)u_2(x) - [f^{-1}(a)]^2 v_2(x) &= F_1, \quad x \in \mathbb{T}, \\
\Delta u_2(0) &= \Delta u_2(T) = \Delta v_2(0) = \Delta v_2(T) = 0,
\end{aligned}
\tag{37}
\]

where

\[
F_1 = \left(\frac{2ab_1}{f^{-1}(a)} - b_1 f'(f^{-1}(a))\right)u_1 + 2f^{-1}(a)u_1 v_1 + \frac{ab_0}{[f^{-1}(a)]^2} u_1.
\tag{38}
\]

In order to solve $b_1$ from (37), let us consider the following adjoint system of the homogeneous system related to (37):
\[
\begin{align*}
&\begin{cases}
\frac{d}{dx} \Delta^2 y_2 (x - 1) + \left( -b_0 f' \left( f^{-1}(a) \right) - f' \left( f^{-1}(a) \right) + \frac{2ab_0}{f^{-1}(a)} \right) y_2 (x) + \left( b_0 f' \left( f^{-1}(a) \right) - \frac{2ab_0}{f^{-1}(a)} \right) z_2 (x) = 0, \quad x \in T, \\
\frac{d}{dx} \Delta^2 z_2 (x - 1) + \left[ f^{-1}(a) \right]^2 y_2 (x) - \left[ f^{-1}(a) \right]^2 z_2 (x) = 0,
\end{cases} \\
\Delta y_2 (0) = \Delta y_2 (T) = \Delta z_2 (0) = \Delta z_2 (T) = 0.
\end{align*}
\tag{39}
\]

It is not difficult to verify that (39) has a solution \( (y_2, z_2) \):

\[
\begin{align*}
y_2 &= c_2 (j) \cos \left( \frac{j\pi}{T} x \right) = c_2 (j) \varphi_j (x), \\
z_2 &= \cos \left( \frac{j\pi}{T} x \right) = \varphi_j (x).
\end{align*}
\tag{40}
\]

By virtue of the solvability condition for (37), it is obvious that

\[
\sum_{x=1}^{T} (z_2 (x) - y_2 (x)) F_1 = 0. 
\tag{41}
\]

From Lemmas 3 and 4, for any \( j \in \{1, 2, \ldots, T - 1\} \) and \( j \neq (2nT/3), n \in \{1, 2, \ldots\} \) we obtain

\[
\sum_{x=1}^{T} \varphi_j^3 (x) = \sum_{x=1}^{T} \cos \left( \frac{3j\pi}{T} x \right) = \frac{1}{4} \sum_{x=1}^{T} \left( \cos \left( \frac{3j\pi}{T} x \right) + 3 \cos \left( \frac{j\pi}{T} x \right) \right) = 0.
\tag{43}
\]
\[
\sum_{x=1}^{T} q_j^3(x) = \frac{1}{4} \left[ \frac{\sin(3j\pi/T)(x - (1/2))}{2 \sin(3j\pi/2T)} \right]^{T+1} + \frac{3}{4} \left[ \frac{\sin(j\pi/T)(x - (1/2))}{2 \sin(j\pi/2T)} \right]^{T+1}
\]
\[
= \frac{1}{4} \frac{\sin((2T + 1)3j\pi/2T) - \sin(3j\pi/2T)}{2 \sin(3j\pi/2T)} + \frac{3}{4} \frac{\sin((2T + 1)j\pi/2T) - \sin(j\pi/2T)}{2 \sin(j\pi/2T)}
\]
\[
= \frac{1}{4} \frac{\cos((2T + 2)3j\pi/2T) \cdot \sin(2T \cdot 3j\pi/2T)}{\sin(3j\pi/2T)} + \frac{3}{4} \frac{\cos((2T + 2)j\pi/2T) \cdot \sin(2T \cdot j\pi/2T)}{\sin(j\pi/2T)} = 0.
\]

Then \(b_1' := b_1 = 0\), and so \(F_1\) will reduce to

\[
F_1 = 2f^{-1}(a)c_1(j)\varphi_j^2(x) + \frac{ab_0}{[f^{-1}(a)]^2c_1^2(j)}\varphi_j^2(x)
\]
\[
= 2f^{-1}(a)c_1(j)\cos^2\left(\frac{j\pi}{T} x\right) + \frac{ab_0}{[f^{-1}(a)]^2c_1^2(j)}\cos^2\left(\frac{j\pi}{T} x\right)
\]
\[
= f^{-1}(a)c_1(j)\left(\cos^2\left(\frac{2j\pi}{T} x\right) + 1\right) + \frac{1}{2} \frac{ab_0}{[f^{-1}(a)]^2c_1^2(j)}\left(\cos^2\left(\frac{2j\pi}{T} x\right) + 1\right)
\]
\[
= \frac{1}{2} \left[2f^{-1}(a)c_1(j) + \frac{ab_0}{[f^{-1}(a)]^2c_1^2(j)}\right]\varphi_j^2(x).
\]

Therefore, a particular solution \((u_2, v_2)\) of (37) can be obtained as follows:

\[
\begin{align*}
\{ & u_2 = a_1(j) + a_2(j)\cos\left(\frac{2j\pi}{T} x\right) = a_1(j) + a_2(j)\varphi_j^2(x), \\
& v_2 = a_3(j) + a_4(j)\cos\left(\frac{2j\pi}{T} x\right) = a_3(j) + a_4(j)\varphi_j^2(x),
\end{align*}
\]

(46)

\[
a_2(j) = \frac{\left[ f^{-1}(a) \right]^2 c_1 d_2 \mu_j + \left(ab_0 d_2 \mu_2 c_1^2 / 2 f^{-1}(a)\right)}{d_1 d_2 \mu_j f^{-1}(a) + f'(f^{-1}(a)) f^{-1}(a) \left(\left[ f^{-1}(a) \right]^2 + d_2 \mu_j (1 + b_0)\right) - 2ab_0 d_2 - d_1 \left[ f^{-1}(a) \right]^2 \mu_j},
\]
\[
a_1(j) = 0,
\]
\[
a_3(j) = a_1(j) + a_2(j)\cos\left(\frac{2j\pi}{T} x\right) = a_1(j) + a_2(j)\varphi_j^2(x),
\]
\[
a_4(j) = \frac{a_1(j) + a_2(j)\cos\left(\frac{2j\pi}{T} x\right)}{d_2 \mu_j a_2(j)}.
\]

(47)

Since \(b_1 = 0\), we have to solve \(b_2\). We substitute (32) and (33) into (4) and let the higher-order term of \(\varepsilon^3\) be equal to 0; then, a problem similar to (37) is obtained:
\[
\begin{aligned}
&d_1 \Delta^2 u_1(x - 1) + \left( -b_0 f'(f^{-1}(a)) - f'(f^{-1}(a)) + \frac{2ab_0}{f^{-1}(a)} \right) u_3(x) + \left[ f^{-1}(a) \right]^2 v_3(x) = -F_2, \quad x \in \mathbb{T}, \\
&d_2 \Delta^2 v_3(x - 1) + \left( b_0 f'(f^{-1}(a)) - \frac{2ab_0}{f^{-1}(a)} \right) u_3(x) - \left[ f^{-1}(a) \right]^2 v_3(x) = F_2, \quad x \in \mathbb{T}, \\
&\Delta u_3(0) = \Delta u_3(T) = \Delta v_3(0) = \Delta v_3(T),
\end{aligned}
\]

where

\[
F_2 = \left( -b_2 f'(f^{-1}(a)) + \frac{2ab_2}{f^{-1}(a)} \right) u_1 + 2f^{-1}(a)u_1v_2 + 2f^{-1}(a)u_2v_1 + \frac{2ab_0}{f^{-1}(a)} u_1u_2.
\]

Clearly, (39) is also the adjoint system of the homogeneous system related to (48); then,

\[
\sum_{x=1}^{T} (z_2(x) - y_2(x))F_2 = 0.
\]

According to values of \( u_1, u_2, v_1, \) and \( v_2, \) we have

\[
\sum_{x=1}^{T} (z_2(x) - y_2(x))F_2
\]

\[
= \sum_{x=1}^{T} \left( -d_2 \mu_j \left[ \frac{2a - f'(f^{-1}(a))f^{-1}(a)}{f^{-1}(a)} \cdot b_2 c_1 \varphi_j(x) + 2f^{-1}(a)c_1 \varphi_j(x)(a_3 + a_4) \varphi_{2j}(x) \\
+ 2f^{-1}(a)a_2 \varphi_{2j}(x) \varphi_j(x) + c_2^2 \varphi_j^3(x) + \frac{2ab_0a_1c_1}{f^{-1}(a)} \varphi_j(x) \varphi_{2j}(x) \right] \right).
\]

From Lemmas 3 and 4, for any \( j \in \{1, 2, \ldots, T - 1\} \) and \( j \neq (nT/2), n \in \{1, 2, \ldots\}, \) we know that

\[
\sum_{x=1}^{T} \varphi_j^3(x) \varphi_{2j}(x) = \frac{T}{4} \cos \left( \frac{j\pi}{T} \right) \cdot \cos \left( \frac{2j\pi}{T} \right) = \frac{1}{2} \left( \frac{T}{2} \right) \cos \left( \frac{4j\pi}{T} x + \frac{2j\pi}{T} x \right) + \frac{T}{4}
\]

\[
= \frac{1}{4} \left[ \sin \left( \frac{4j\pi}{T} (x - (1/2)/T) \right) \right]_{1}^{T+1} + \frac{1}{2} \left[ \sin \left( \frac{2j\pi (x - (1/2)/T) \right) \right]_{1}^{T+1} + \frac{T}{4}
\]

\[
= \frac{1}{4} \left( 2 \cos \left( (2T + 2) \frac{jin(T)}{2} \right) \sin \left( (2j \cdot 2T) \right) \right) + \frac{1}{2} \left( \frac{2 \cos \left( (2T + 2) \frac{j\pi}{T} \right) \sin \left( (2j \cdot 2T) \right) }{2 \sin (2j\pi / T) } \right) + \frac{T}{4} = \frac{T}{4} \neq 0.
\]

Thus,

\[
b_j^2 = b_j \neq 0, \quad j = 1, 2, \ldots, T - 1.
\]

From the above analysis, we obtain the main result of this section.

**Theorem 1.** Assume that (H1) and (H2) hold. Then, for any positive integer \( j < T, j \neq (nT/2) \) and \( j \neq (2nT/3), n \in \{1, 2, \ldots\}, \) \( (b_0, \varnothing) \) is a bifurcation point of \( P(b, \varnothing) = \begin{pmatrix} 0 \\ 0 \end{pmatrix} \).

Moreover, there is a nontrivial solution \( \phi(\epsilon) = (b(\epsilon), \ldots) \),
\[ u(\epsilon), v(\epsilon) \text{ of (4) if } \epsilon \text{ is small enough, where } b, u, \text{ and } v \text{ are continuous with respect to } \epsilon: \]
\[ u(\epsilon) = f^{-1}(a) + \epsilon c_1(j) \varphi_j + \epsilon^2 \left( a_1(j) + a_2(j) \varphi_j \right) + o(\epsilon^2), \]
\[ v(\epsilon) = \frac{ab}{f^{-1}(a)} + \epsilon \varphi_j + \epsilon^2 \left( a_4(j) + a_4(j) \varphi_j \right) + o(\epsilon^2), \]
\[ b(\epsilon) = b_0^j + \epsilon^2 b_2^j + o(\epsilon^2). \]

The set of zero-points of \( P \) constitutes two curves in a neighborhood of bifurcation point \((b_0^j, w)\).

Let \( C \) be the closure of the nonconstant solution set of \( P(b, w) = \begin{pmatrix} 0 \\ 0 \end{pmatrix} \) and \( \Gamma_j \) be a connected component of \( C \cup \{(b_0^j, w)\} \) and \( \chi \in \Gamma_j \). In a small neighborhood of bifurcation point \((b_0^j, w)\), the curve \( \Gamma_j \) is determined by the eigenfunction \( \varphi_j \), where \( \varphi_j \) has exactly \( j - 1 \) simple generalized zeros.

\[ \begin{align*}
-\Delta^2 \tilde{u}(x - 1) &= g_0 \tilde{u}(x) + g_1 \tilde{v}(x) + \tilde{g}(\tilde{u}(x), \tilde{v}(x)), \quad x \in \mathbb{T}, \\
-\Delta^2 \tilde{v}(x - 1) &= h_0 \tilde{u}(x) + h_1 \tilde{v}(x) + \tilde{h}(\tilde{u}(x), \tilde{v}(x)), \quad x \in \mathbb{T}, \\
\Delta \tilde{u}(0) &= \Delta \tilde{u}(T) = \Delta \tilde{v}(0) = \Delta \tilde{v}(T) = 0,
\end{align*} \]

where \( \tilde{g} \) and \( \tilde{h} \) are higher-order terms of \( \tilde{u}, \tilde{v} \) and

\[ \begin{align*}
g_0 &= g_0(u, v) \left( f^{-1}(a), ab[ f^{-1}(a) ]^2 \right) = \frac{1}{d_1} \left( -b + 1 \right) f' \left( f^{-1}(a) \right) + \frac{2ab}{f^{-1}(a)}, \\
g_1 &= g_1(u, v) \left( f^{-1}(a), ab[ f^{-1}(a) ]^2 \right) = \frac{f^{-1}(a)^2}{d_1}, \\
h_0 &= h_0(u, v) \left( f^{-1}(a), ab[ f^{-1}(a) ]^2 \right) = \frac{1}{d_2} \left( b f' \left( f^{-1}(a) \right) - 2ab \right), \\
h_1 &= h_1(u, v) \left( f^{-1}(a), ab[ f^{-1}(a) ]^2 \right) = \frac{f^{-1}(a)^2}{d_2},
\end{align*} \]

In this way, we convert the constant solution \( \mathcal{w} = \left( f^{-1}(a), ab[ f^{-1}(a) ]^2 \right) \) of (4) to the trivial solution \( \theta = (0, 0) \) of (57).

Let \( H_1: Y \rightarrow X \) and \( H_2: Y \rightarrow X \) be the inverse of operators \( (f^2(f^{-1}(a))/d_1)I - A \) and \( (f^2(f^{-1}(a))/d_2)I - A \)

\[ K(b)U = \left( \frac{1}{d_1} \left[ -b f' \left( f^{-1}(a) \right) + \frac{2ab}{f^{-1}(a)} \right] H_1(\tilde{u}) \right) + \left( \frac{f^{-1}(a)^2}{d_1} \right) H_1(\tilde{v}), \]
\[ W(U) = \left( H_1(\tilde{g}(\tilde{u}, \tilde{v})), H_2(\tilde{h}(\tilde{u}, \tilde{v})) \right), \]

\[ 4. \text{ Global Bifurcation} \]

\textbf{Theorem 2.} Let \((H1), (H2), \text{ and } (H3) \text{ hold. If } \mu_j \neq \left( f^{-1}(a) \right)^2/d_2, j = 1, 2, \ldots, T, \text{ then projection of continuous } \Gamma_j \text{ is unbounded on the b-axis.} \]

\textbf{Proof.} (4) can be written as follows:
\[ \begin{align*}
-\Delta^2 u(x - 1) &= g(u(x), v(x)), \quad x \in \mathbb{T}, \\
-\Delta^2 v(x - 1) &= h(u(x), v(x)), \quad x \in \mathbb{T}, \\
\Delta u(0) &= \Delta u(T) = \Delta v(0) = \Delta v(T) = 0,
\end{align*} \]

where
\[ g(u, v) = \frac{1}{d_1} \left( a - (b + 1)f(u) + u^2 v \right), \]
\[ h(u, v) = \frac{1}{d_2} \left( b f(u) - u^2 v \right). \]

Let \( \tilde{u} = u - f^{-1}(a), \tilde{v} = v - ab[ f^{-1}(a) ]^2. \) Then, (55) is equivalent to the following problem:

\[ \begin{align*}
-\Delta^2 \tilde{u}(x - 1) &= g_0 \tilde{u}(x) + g_1 \tilde{v}(x) + \tilde{g}(\tilde{u}(x), \tilde{v}(x)), \quad x \in \mathbb{T}, \\
-\Delta^2 \tilde{v}(x - 1) &= h_0 \tilde{u}(x) + h_1 \tilde{v}(x) + \tilde{h}(\tilde{u}(x), \tilde{v}(x)), \quad x \in \mathbb{T}, \\
\Delta \tilde{u}(0) &= \Delta \tilde{u}(T) = \Delta \tilde{v}(0) = \Delta \tilde{v}(T) = 0,
\end{align*} \]

with Neumann boundary conditions, respectively, where \( A: [0, \infty) \rightarrow (-\infty, 0] \) and \( Au(x) = \Delta^2 u(x - 1). \) Set \( U = (\tilde{u}, \tilde{v}); \)
It can be verified that (57) is equivalent to
\[ U = K(b)U + W(U), \tag{60} \]
in \( X \). For any fixed \( b > 0 \), \( K(b) \) and \( W(U) \) are linear compact operators in \( X \) and \( W(U) = o([U]) \). By the Rabinowitz global bifurcation theorem [24], we need to verify

(i) 1 is an eigenvalue of \( K(b) \), and its algebraic multiplicity is 1

(ii) The index of \( I - K(b) - W \) changes when \( b \) crosses \( b_0^j \).

Now, we will prove (i). Suppose \( \Psi = \begin{pmatrix} \xi \\ \psi \end{pmatrix} \), \( \xi = \sum a_j \varphi_j \), \( \psi = \sum c_j \varphi_j \). Let
\[ (K(b) - I)\Psi = \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \tag{61} \]
i.e.,

\[
\begin{pmatrix}
\frac{1}{d_1}(-b + 1)f'(f^{-1}(a)) + \frac{2ab}{f^{-1}(a)} + A & \frac{[f^{-1}(a)]^2}{d_1} \\
\frac{1}{d_2}bf'(f^{-1}(a)) - \frac{2ab}{f^{-1}(a)} & - \frac{[f^{-1}(a)]^2}{d_2} + A
\end{pmatrix} \begin{pmatrix} \xi \\ \psi \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}.
\]

Thus,
\[ \sum_{j=0}^{\infty} L_j \begin{pmatrix} a_j \\ c_j \end{pmatrix} \varphi_j = \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \tag{62} \]

where

\[ L_j = \begin{pmatrix}
\frac{1}{d_1}(-b + 1)f'(f^{-1}(a)) + \frac{2ab}{f^{-1}(a)} - \mu_j & \frac{[f^{-1}(a)]^2}{d_1} \\
\frac{1}{d_2}bf'(f^{-1}(a)) - \frac{2ab}{f^{-1}(a)} & - \frac{[f^{-1}(a)]^2}{d_2} - \mu_j
\end{pmatrix} + A \begin{pmatrix} \xi \\ \psi \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}.
\]

By computation, \( \det L_j = 0 \) if and only if \( b = b_0^j \); taking \( b = b_0^j \) leads to
\[ L_j \begin{pmatrix} a_j \\ c_j \end{pmatrix} = \begin{pmatrix} 0 \\ f'(f^{-1}(a)) + d_1 \mu_j + d_2 \mu_j \end{pmatrix} \begin{pmatrix} a_j \\ c_j \end{pmatrix}. \tag{63} \]

Then, \( d_2 \mu_j \ker(K(b_0^j) - I) = \text{span}(\Psi), \Psi = \begin{pmatrix} f'(f^{-1}(a)) + d_1 \mu_j \end{pmatrix} \varphi_j \). This implies that 1 is the eigenvalue of \( K = K(b_0^j) \) and \( \text{dim} \ker (K - I) = 1 \). The algebraic multiplicity of eigenvalue 1 is the dimension of the generalized null space \( \cap_{i=1}^{\infty} \ker (K - I)^i \); therefore, \( \ker (K - I) \cap \text{Im} (K - I) = \{ \varphi \} \).

Let \( K^T \) be the transposed matrix of \( K \):

\[
K^T = \begin{pmatrix}
\frac{1}{d_1}(-b + 1)f'(f^{-1}(a)) + \frac{2ab}{f^{-1}(a)} H_1 & \frac{[f^{-1}(a)]^2}{d_1} H_1 \\
\frac{1}{d_2}bf'(f^{-1}(a)) - \frac{2ab}{f^{-1}(a)} H_2 & 0
\end{pmatrix},
\]

and \( \Psi^* = \begin{pmatrix} \xi^* \\ \psi^* \end{pmatrix} \), \( \xi^* = \sum a_j^* \varphi_j, \psi^* = \sum c_j^* \varphi_j \). Suppose \( \Psi^* \in \ker(K^T - I) \). Then,
\[
\begin{aligned}
\frac{1}{d_1} & -b f'(f^{-1}(a)) + \frac{2ab}{f^{-1}(a)} H_1(\xi^*) + \frac{1}{d_2} \left[ b f'(f^{-1}(a)) - \frac{2ab}{f^{-1}(a)} \right] H_2(\psi^*) = \xi^*, \\
\left[ f^{-1}(a) \right]^2 & d_1 H_1(\xi^*) = \psi^*.
\end{aligned}
\] (67)

From the definition of \( H_1 \) and \( H_2 \), (67) can also be written as

\[
\begin{aligned}
-\frac{d_1 d_2 \Delta^2 \xi^* (x - 1)}{-d_1 \Delta^2 \psi^* (x - 1)} & = \left( \frac{d_2}{-d_1} \right) \left[ -b f'(f^{-1}(a)) + \frac{2ab}{f^{-1}(a)} \right] - [f^{-1}(a)]^2 \frac{d_1}{d_2} - d_1 d_2 \mu_j - \frac{d_2 f'(f^{-1}(a))}{[f^{-1}(a)]^2} \left[ -b f'(f^{-1}(a)) + \frac{2ab}{f^{-1}(a)} \right] \psi^*, \\
\end{aligned}
\] (68)

That is to say,

\[
\sum_{j=0}^{\infty} B_j \begin{pmatrix} a_j^* \\ c_j^* \end{pmatrix} \Phi_j = \begin{pmatrix} 0 \\ 0 \end{pmatrix}.
\] (69)

\[
B_j = \begin{pmatrix} d_2 \left[ -b f'(f^{-1}(a)) + \frac{2ab}{f^{-1}(a)} \right] - [f^{-1}(a)]^2 \frac{d_1}{d_2} - d_1 d_2 \mu_j - \frac{d_2 f'(f^{-1}(a))}{[f^{-1}(a)]^2} \left[ -b f'(f^{-1}(a)) + \frac{2ab}{f^{-1}(a)} \right] \\
\left[ f^{-1}(a) \right]^2 \\
\end{pmatrix}.
\] (70)

Similarly, \( \det B_j = 0 \) if and only if \( b = b_0^j \), taking \( b = b_0^j \) leads to

\[
B_j \begin{pmatrix} a_j^* \\ c_j^* \end{pmatrix} = \begin{pmatrix} 0 \\ [f^{-1}(a)]^2 - d_1 d_2 \mu_j - f'(f^{-1}(a)) \end{pmatrix} \begin{pmatrix} a_j^* \\ c_j^* \end{pmatrix}.
\] (71)

\[
(P, \Psi^*) = \sum_{x=1}^{T} \left( -d_2 \mu_j \left( d_1 \mu_j + f'(f^{-1}(a)) \right) \left[ f^{-1}(a) \right]^2 - d_2 \mu_j \right) \sum_{x=1}^{T} \Phi_j^2 (x) + \sum_{x=1}^{T} \left( f'(f^{-1}(a)) + d_1 \mu_j \right) \left[ f^{-1}(a) \right]^2 \Phi_j^2 (x)
\]

\[
= \left( d_1 \mu_j + f'(f^{-1}(a)) \right) \left[ f^{-1}(a) \right]^2 - d_2 \mu_j \sum_{x=1}^{T} \Phi_j^2 (x)
\]

\[
= \left( d_1 \mu_j + f'(f^{-1}(a)) \right) \left[ f^{-1}(a) \right]^2 - d_2 \mu_j \sum_{x=1}^{T} \cos \left( \frac{j \pi}{T} x \right)
\]

\[
= \left( d_1 \mu_j + f'(f^{-1}(a)) \right) \left[ f^{-1}(a) \right]^2 - d_2 \mu_j \left( \frac{1}{2} \sum_{x=1}^{T} \cos \left( \frac{2j \pi}{T} x \right) + 1 \right)
\]

\[
= \left( d_1 \mu_j + f'(f^{-1}(a)) \right) \left[ f^{-1}(a) \right]^2 - d_2 \mu_j \left( \frac{1}{2} \cos \left( \frac{(2T + 2)j \pi}{T} \right) \sin \left( \frac{2 \pi}{T} x \right) + \frac{2 \pi}{T} + 1 \right) \neq 0.
\] (72)
This suggests that \( \Psi \notin (\ker(K^* - I))^\perp = \text{Im}(K - I) \), and so (i) is proved.

Now, we will prove (ii). From (i), for any \( b > 0 \), \( b \neq b_0 \) and \( b \) belongs to a small neighborhood of \( b_0 \), and \( K(b) - I : X \rightarrow X \) is a bijection. Fix \( b > 0 \); then, \( \theta \) is a solution of (60), and \( \theta \) is isolated. From Leray–Schauder fixed point theory, we can get

\[
\text{index}(I - K(b^\ell - \varepsilon) - W, (b^\ell - \varepsilon, \theta)) \neq \text{index}(I - K(b^\ell + \varepsilon) - W, (b^\ell + \varepsilon, \theta)).
\]

If \( \tau \) is an eigenvalue of \( K(b) \) and \( \Psi = \begin{pmatrix} \xi \\ \psi \end{pmatrix} \) is the corresponding eigenfunction, then

\[
(K(b) - I)\Psi = \begin{pmatrix} 0 \\ 0 \end{pmatrix},
\]

\[
\left\{ \begin{align*}
-\tau d_1 \Delta^2 \xi(x - 1) &= \left(-bf'\left(f^{-1}(a)\right) + \frac{2ab}{f^{-1}(a)} - \tau f'\left(f^{-1}(a)\right)\right)\xi(x) + \left[f^{-1}(a)\right]^2\psi(x), & x \in \mathbb{T}, \\
-\tau d_2 \Delta^2 \psi(x - 1) &= \left(bf'\left(f^{-1}(a)\right) - \frac{2ab}{f^{-1}(a)}\right)\xi(x) - \left[f^{-1}(a)\right]^2\tau\psi(x), & x \in \mathbb{T}.
\end{align*} \right.
\]

By virtue of \( \xi = \sum a_i \varphi_j \) and \( \psi = \sum c_i \varphi_j \), we can get

\[
\sum_{j=0}^{\infty} \begin{pmatrix} \tau \mu_j d_1 + bf'\left(f^{-1}(a)\right) - \frac{2ab}{f^{-1}(a)} + \tau f'\left(f^{-1}(a)\right) - \left[f^{-1}(a)\right]^2 \\ -bf'\left(f^{-1}(a)\right) + \frac{2ab}{f^{-1}(a)} \end{pmatrix} \begin{pmatrix} a_j \\ c_j \end{pmatrix} \varphi_j = \begin{pmatrix} 0 \\ 0 \end{pmatrix}.
\]

Then, the characteristic equation is

\[
\left( d_1 d_2 \mu_j^\ell + d_2 \mu_j f'\left(f^{-1}(a)\right) + d_1 \mu_j \left[f^{-1}(a)\right]^2 + f'\left(f^{-1}(a)\right)\left[f^{-1}(a)\right]^2\right) \tau^2 \\
+ b\left( d_2 f'\left(f^{-1}(a)\right)\mu_j - \frac{2ad_1 \mu_j}{f^{-1}(a)} + f'\left(f^{-1}(a)\right)\left[f^{-1}(a)\right]^2 - 2af^{-1}(a)\right) \tau + \left[f^{-1}(a)\right]^2\left(-bf'\left(f^{-1}(a)\right) + \frac{2ab}{f^{-1}(a)}\right) = 0,
\]

\[
j = 0, 1, 2, \ldots, T.
\]
If \( r = 1 \), \( b \) can be solved from (78):

\[
b = \frac{f^{-1}(a)\left[d_1d_2\mu_j^2 + d_2f'(f^{-1}(a))\mu_j + a\left[f^{-1}(a)^2\right] + d_1\left[f^{-1}(a)^2\right]^2f'(f^{-1}(a))\right]}{2ad_2\mu_j - d_2f^{-1}(a)f'(f^{-1}(a))\mu_j} = b_j^i,
\]

(79)

Therefore, by calculating the corresponding eigenvalues of (78), we can obtain that when \( b \) passes through \( b_0^i \), the number of eigenvalues of \( K(b) \) which is greater than 1 is the same, and their algebraic multiplicity are equal. By plugging (79) into (78), we have

\[
\frac{2ad_2\mu_j - d_2f^{-1}(a)f'(f^{-1}(a))\mu_j}{f^{-1}(a)}\tau^2 + \left(f'(f^{-1}(a))\left[d_2\mu_j + f^{-1}(a)^2\right] - 2ad_2\mu_j - 2af^{-1}(a)\right)\tau + \left[f^{-1}(a)^2\right]^2 - 2af^{-1}(a) = 0.
\]

(80)

Then,

\[
\left(d_2f'(f^{-1}(a))\mu_j - \frac{2ad_2\mu_j}{f^{-1}(a)} + f'(f^{-1}(a))\left[f^{-1}(a)^2 - 2af^{-1}(a)\right] - 4\left(2ad_2\mu_j - d_2f^{-1}(a)f'(f^{-1}(a))\mu_j\right)\right)^2 - 4\left(2ad_2\mu_j - d_2f^{-1}(a)f'(f^{-1}(a))\mu_j\right)\left(-f'(f^{-1}(a))f^{-1}(a) + 2a\right)
\]

(81)

and so (80) has two different roots \( \tau_1 = 1, \tau_2 = [f^{-1}(a)^2]/d_2 \). Thus, two things will happen:

(a) If \( \mu_j > [f^{-1}(a)]^2/d_2 \), then \( \tau_1(b_0^i) = 1, \tau_2(b_0^i) < 1 \).

(b) If \( \mu_j < [f^{-1}(a)]^2/d_2 \), then \( \tau_1(b_0^i) = 1, \tau_2(b_0^i) > 1 \).

When scenario (a) occurs, \( b \) passes through \( b_0^i \) and \( \tau_2(b) < 1 \). From (78), \( \tau_1(b_0^i + \varepsilon) > 1, \tau_1(b_0^i - \varepsilon) < 1 \). Therefore, the matrix \( K(b_0^i + \varepsilon) \) has exactly one more eigenvalue than \( K(b_0^i - \varepsilon) \) does, and its algebraic multiplicity is 1. Then, (74) holds. That is to say, the index jumps as \( b \) goes through \( b_0^i \).

When scenario (b) occurs, \( b \) passes through \( b_0^i \) and \( \tau_2(b) > 1 \). From (78), \( \tau_1(b_0^i + \varepsilon) > 1, \tau_1(b_0^i - \varepsilon) < 1 \). Similarly, the index jumps as \( b \) goes through \( b_0^i \). Therefore, (ii) is true regardless of (a) or (b).

Thus, by the index jump principle and [24], Theorem 1.3, it follows that there exists a connected component \( \Gamma_j \) of nontrivial solutions of (60), and \( \Gamma_j \) comes from the bifurcation point \( (b_0^i, \theta) \). We know that \( \Gamma_j \) is also the connected component \( \Gamma_j \) of the nonconstant solution of (4) from \((b_0^i, \varphi_j)\). \( \Gamma_j \) and \( \Gamma_j \) are both in \( \mathbb{R} \times X \). By the Rabinowitz global bifurcation theorem, the connected component \( \Gamma_j \) joins \((b_0^i, \varphi_j)\) to either \( \varphi_j \) or \((b_0^i, \varphi_j)\) in \( \mathbb{R} \times X \), where \( k \neq j \).

We first prove that the latter situation will not happen. According to Theorem 1, the solution on the connected component sent from \((b_0^i, \varphi_j)\) is related to \( \varphi_j \), and \( \varphi_j \) has exactly \( j - 1 \) simple generalized zeros. In the same way, the solution on the connected component sent from \((b_0^i, \varphi_k)\) is related to \( \varphi_k \), and \( \varphi_k \) has \( k - 1 \) simple generalized zeros. If the connected component sent \( \Gamma_j \) joining \((b_0^i, \varphi_j)\) to \((b_0^i, \varphi_k)\), the solution \((b, \varphi) \in \Gamma_j \) is related to both \( \varphi_j \) and \( \varphi_k \), which is impossible. On the contrary, Lemma 1 shows that if \( b = b_0 \in (0, \infty) \), then the solutions \( u \) and \( v \) of (4) are both bounded. So, the connected component \( \Gamma_j \) will not join \((b_0^i, \varphi_j)\) to \((b_0^i, \varphi_k)\). Therefore, the connected component \( \Gamma_j \) can only join \((b_0^i, \varphi_j)\) to either \((\infty, \infty)\) or \((\infty, m)\), where \( m \in (0, \infty) \). But, in any case, the projection of continuum \( \Gamma_j \) is unbounded on the \( b \)-axis.
