Aim. To determine the implication of the polymorphism, namely, $A(TA)_nTAA$ of $UGT1A1$ in lithogenesis for the first time in Tunisia among sickle cell anemia (SCA) children patients. Material and Methods. Our study was performed in 2010 and it involved 76 subjects chosen as control group characterized with normal hemoglobin status and presence of cholelithiasis and 102 SCA pediatric patients among whom 52 have cholelithiasis. We analyzed the polymorphism $A(TA)_nTAA$ at the $UGT1A1$ promoter and the relationships between the various $A(TA)_nTAA$ genotypes and alleles and bilirubin levels and occurrence of cholelithiasis. Results and Discussion. The repartition of genotypes found according to serum bilirubin level shows a significant association between genotypes carrying variant $(TA)_7$ and hyperbilirubinemia ($P<0.05$). We demonstrated the association of two genotypes with gallstones formation among SCA children patients: $(TA)_7/(TA)_7$ and $(TA)_7/(TA)_8$ with $P=8.1\times10^{-8}$ and $P=0.01$, respectively. $(TA)_7$ and $(TA)_8$ allele variants act as a risk factor for early gallstones formation in SCA patients with $P=5.8\times10^{-9}$ and $P=0.01$, respectively. As for the control group only the genotype $(TA)_7/(TA)_7$ presented a risk factor for gallstones formation. Conclusion. The novelty of this report is that it is the first time that a similar study was made on the Tunisian children sickle cell population and that the results show a clear association of $(TA)_7$ variant in early gallstones formation in Tunisian SCA children. Interestingly our findings highlighted the association of $(TA)_8$ variant as well, which was not found in previous studies.

1. Introduction

SCA is a heterogeneous monogenic disease due to a single mutation A/T at the sixth codon of the β-globin gene (βS) [1]. The clinical complications arising from sickle cell disease include vasoo-cclusive crisis and its outcomes [1]. As a result of chronic hemolysis, hyperbilirubinemia is often observed leading to the formation of pigment cholelithiasis which could be busted by the presence of $UGT1A1$ defects. Indeed $UGT1A1$ gene encodes the uridine diphosphate glucuronosyltransferase 1A1, enzyme responsible for bilirubin glucuronidation [2]. The $UGT1A1$ gene is located in chromosome 2q37 [3]. Various $UGT1A1$ gene defects and polymorphisms have been described so far at the origin of reduced enzyme activity [4]. Among these, a variation in the number of TA repeat at the $A(TA)_nTAA$ nucleotide sequence in the promoter region, considered as the wild type. In fact, the addition of an extra (TA) at this sequence leads to a variant $A(TA)_nTAA$ which was described to cause reduced glucuronidation and hyperbilirubinemia associated with the Gilbert syndrome [2, 5]. This variation at the promoter seems to interfere with binding of the transcription factor IID which is responsible for the transcription of $UGT1A1$ gene. In fact, the $A(TA)_nTAA$ element is the binding site for transcription factor IID, which is one of the factors responsible for the initiation of transcription and the presence of this longer $A(TA)_nTAA$ element in the promoter region of the gene for bilirubin UDP-glucuronosyltransferase I resulting in reduced expression of bilirubin-UGT1 (30% of normal) and hence causing unconjugated hyperbilirubinemia [3]. Studies of a
possible association between polymorphisms of candidate
genes related to the modulation of clinical complications
of SCA have shown that sickle cell patients who carry the
variation (TA), are favorable for gallstone formation [4–
11]. Besides, other studies have shown the correlation of
cholelithiasis and A(TA)_n-TAA variant of UGT1A1 promoter
with chronic hemolytic diseases such as thalassemia minor,
which represent a risk factor for cholelithiasis and the Gilbert
mutation further increases this risk [12–16]. The prevalence of
cholelithiasis observed in SCA children is about 30% reported
for different ethnic groups (United States, Guadeloupe)
[17, 18].

In this paper, we intend to study the impact of
A(TA)_n TAA variation at the UGT1A1 gene promoter on
hyperbilirubinemia and on the occurrence of cholelithiasis
for the first time among SCA Tunisian children. SCA is
the second sickle cell hemoglobinopathy after β-thalassemia
in Tunisia, representing a real public health problem. The
average frequency of the trait in our country is 1.89% [19].
The organization of care of sickle cell disease children in Tunisia
is the National Center of Bone Marrow Transplantation.

2. Methods

2.1. Subjects. 76 subjects with cholelithiasis and 102 sickle
cell patients were involved in this study performed in 2010.
Patients were selected on the basis of homozygosity for β-
globin gene from National Center of Bone Marrow Trans-
plantation, Tunis, Tunisia. All SCA patients are children (less
than 16 years old) and were characterized by hyperbilirubine-
mia and 52 of them have cholelithiasis.

2.2. Methods

2.2.1. Clinical Events Analyzed. Liver/biliary ultrasound
scans were performed annually to detect cholelithiasis only
in SCA patients over the age of three years. Cholelithiasis
was diagnosed for all patients on the basis of echodense
images within the gallbladder with acoustic shadowing or
gravitational change in position.

2.2.2. Laboratory Methods. Diagnosis of sickle cell patient is
performed using cation-exchange high-performance liquid
chromatography (HPLC) (D10 Biorad) and further confir-
mation by means of molecular diagnosis by restriction
fragment length polymorphism (RFLP) using Ddel as pre-
viously described by Bachir 2000 [20]. Biochemical data
were averaged for each patient in steady state (at least three
values). We determined total and fetal hemoglobin (HbF)
concentrations (D10, Biorad) and reticulocyte count and
other hematologic parameters using (ABX pentra 60c+).
Total unconjugated and conjugated bilirubin concentrations
in serum were determined by a standardized colorimetric
procedure (Cobras Integra, Meylan, France).

2.2.3. A(TA)_n TAA Genotyping. Genomic DNA was isolated
from white blood cells of total blood using standard method
(phenol/chloroform). A(TA)_n TAA sequences were genotyped
by polymerase chain reaction (PCR) using a couple of
primers, namely, TAF: 5′-TCGTCCCTTCTCCTCTG-3′
and TAR: 5′-TCCTGCTCCTGCCAGAGGT-3′. Poly-
merase chain reaction was performed in 25μL reaction
volumes containing 100 ng of genomic DNA, 0.2 mmol/L of
each dNTP, 50 mmol/L KCl, 15 mmol/L Tris-HCl PH 8.0,
2.5 mmol/L MgCl_2, 0.5 U AmpliTaq polymerase (Invitrogen
Life Technologies, Carlsbad, CA, USA), and 10 pmol of each
forward and reverse primers. The PCR cycling conditions
included an initial denaturation of 10 min at 96°C followed
by 35 cycles of 96°C for 30 s, annealing at 58°C for 30 s, and
extension at 72°C for 1 min. The run was ended by a final
extension at 72°C for 7 min.

PCR products were then purified and doubly sequenced
(forward and reverse) by ABI PRISM Big Dye Terminator
on Ready Reaction Kit (Applied Biosystems, Foster City,
CA, USA) and an ABI 310 DNA sequencer (PEApplied
Biosystems, Foster City, USA).

2.3. Data Analysis. The sample of SCA patients was divided
into two groups according to the presence or absence
of cholelithiasis. 76 patients with normal hemoglobin (AA)
and presented cholelithiasis were enrolled in the analysis. We
compared demographic and hematological and clinical data
between the groups of patients. As for A(TA)_n TAA polymor-
phism genetic differences between the groups were evaluated.
We defined two intervals of total bilirubin levels. The first
includes total bilirubin value <35 μmol/L which is the critical
value of total bilirubin associated with the Gilbert syndrome.
The second interval includes bilirubin value higher than the
cutting point 35 μmol/L. We investigated the relationships
between genotypes found and these intervals.

2.4. Statistical Analysis. The demographic and hematologic
data are normally distributed, so we used means and standard
deviations. The bilirubin data are not normally distributed,
so we used medians. For each variable (demographic, hema-
tological, and biochemical) differences between cases and
controls were evaluated applying the t-test or the nonpara-
metric Mann-Whitney test as appropriate using SPSS (version
18). The Hardy-Weinberg equilibrium was tested using the
software package Arlequin (version 3.01). Genetic differences
between cases and controls were evaluated applying exact
tests to genotypic or allelic contingency tables using compare
2 (version 1.02). The relationships between genotypes found
and total bilirubin level were evaluated applying Fisher’s exact
test using compare 2 (version 1.02). We calculated P values
for the entire tests and Fisher’s exact test and chi-squared test
were used as appropriate.

3. Results

3.1. Demographic, Hematological, and Biochemical Analysis.
The distribution of each continuous variable was performed
using the nonparametric Mann-Whitney test. Our results
show that there is no significant difference between the two
groups of SCA patient according to the presence or the
absence of cholelithiasis (P > 0.05), whereas, the comparison

Usual value of total bilirubin level is <17 µmol/L.
SS: homozygous of β-globin gene mutation.
AA: normal adult hemoglobin.
The demographic and hematologic values are indicated as mean ± standard deviation.
The bilirubin values are indicated as medians.
Statistics for the comparison of demographic and hematological variables between the two groups were performed using the t-test and chi-square test as appropriate (SPSS 18.0).
Statistics for the comparison of bilirubin level between the two groups were performed using the nonparametric Mann-Whitney test (SPSS 18.0).
P: index of significance, each P < 0.05 is considered as significant. P1: comparison between SCA patients according to the presence or the absence of choledolithiasis. P2: comparison between SCA patients without choledolithiasis and patients with choledolithiasis.

of total conjugated and unconjugated bilirubin concentrations between the two groups of SS children patients shows a significant difference with P < 0.05. Our findings show a significant difference between SCA patients and patients with choledolithiasis considered as control group with P < 0.05 (Table 1).

3.2. Analysis of the A(TA)n TAA Polymorphism. All samples were found to be in Hardy-Weinberg equilibrium (P = 0.09) for A(TA)n TAA polymorphism. Our results show the presence of seven genotypes, namely, (TA)7/(TA)7, (TA)6/(TA)6, (TA)5/(TA)5, (TA)7/(TA)7, (TA)7/(TA)7, (TA)5/(TA)5, (TA)7/(TA)7, and (TA)5/(TA)5. The distribution of genotypes between children with gallstones and who are without gallstones and the control group are shown in Table 2. The comparison of these genotypes according to the number of (TA) reported that the genotypes (TA)7/(TA)7 and (TA)5/(TA)5 were significantly associated with SCA patients with gallstones (P < 0.05). Our results show a significant association between genotype (TA)7/(TA)7 and gallstones in the control group. Moreover, (TA)7 and (TA)5 allelic variants are found to be associated with gallstones in SCA children patients (P < 0.05) Table 2. Association is not found in the control group.

3.3. Relationship between Total Bilirubin Levels and A(TA)n TAA Polymorphism. The repartition of different genotypes depending on two intervals representing bilirubin level in SCA children shows that genotypes carrying (TA)7 and (TA)5 alleles are associated with increased bilirubin level. Similar results were found in the control group (Tables 3(a) and 3(b)).

4. Discussion

In the current study we tested 102 SCA Tunisian children patients among whom 52 have choledolithiasis and 76 subjects were chosen as control group characterized with normal hemoglobin status and presence of choledolithiasis and analyzed the polymorphism at the promoter and the relationships between the various UGT1A1 promoter genotypes and alleles and bilirubin levels. In a previous study we were interested to determine the frequency of A(TA)n TAA and
Table 2: Distribution of A(TA)<sub>n</sub>TAA genotypes and allele frequency according to the presence or absence of cholelithiasis in the sample of patients.

Gly71Arg of UGT1A1 in a healthy population [21]. The polymorphism A(TA)<sub>n</sub>TAA showed that genotype (TA)<sub>7</sub>/(TA)<sub>7</sub> described as being associated with Gilbert’s syndrome was encountered in 11% of the population studied. This percentage is close to the value described in the Caucasian population, estimated at 10% [22, 23]. Concerning the polymorphism Gly71Arg, our results show that the mutated allele is encountered in 15.7% of our studied population. This frequency differs greatly from that reported for Caucasians and Afro-Americans but it is similar to that perceived at the Japanese population [24–28]. All these results suggest that the Tunisian population appears to be heterogeneous for UGT1A1 gene mutation status. The heterogeneity of Tunisian population for SCA haplotypes has been reported previously by Imen et al., 2011 [4]. The authors have demonstrated the predominance of the Benin haplotype in SCA patients suggests that the BS mutation present in Tunisia may have originated from the Benin region and was brought to Tunisia along the slave trade routes. However, they have reported the presence of another atypical haplotype that could be considered as specific to Tunisian chromosome BS. In a previous study we have been interested in the implication of the polymorphism A(TA)<sub>n</sub>TAA of UGT1A1 in occurrence of cholelithiasis among Tunisian patients with normal hemoglobin status. Our findings have showed that subjects with (TA)<sub>8</sub> or (TA)<sub>9</sub> variant in their genotypes are associated with high bilirubin level. Furthermore, we have demonstrated that (TA)<sub>7</sub>/(TA)<sub>7</sub> and (TA)<sub>7</sub>/(TA)<sub>7</sub> genotypes and (TA)<sub>7</sub> and (TA)<sub>8</sub> alleles were significantly associated with an increased risk of gallstone diseases. In this study, our results show that total bilirubin level increased with the genotypes (TA)<sub>6</sub>/(TA)<sub>7</sub>, (TA)<sub>7</sub>/(TA)<sub>7</sub>, and (TA)<sub>7</sub>/(TA)<sub>8</sub>.
(P = 7.1 × 10^{-7}; P = 2.4 × 10^{-16}; and P = 8.2 × 10^{-7}), respectively. In fact, the addition of an extra (TA) at the TATA box seems to interfere with binding of the transcription factor IID which is responsible for the transcription of UGT1A1 gene. This interference leads to the reduced expression of UGT1A1 and hence in the expression of bilirubin-UGT1 (30% of normal) [2]. Furthermore, our findings show a significant association between genotypes (TA)_{7}/(TA)_{5} and (TA)_{7}/(TA)_{8} and cholelithiasis in SCA children patients with a P value of 8.1 × 10^{-8} and P = 0.01, respectively. (TA)_{7} and (TA)_{8} allele variants are found to be associated with cholelithiasis among SCA children with P = 5.8 × 10^{-9} and P = 0.01, respectively. In order to interpret the effect of the A(TA)_{n} TAA promoter polymorphism on the lithogenesis in SCA patients our results were compared against those of a control group. We demonstrated that the genotype (TA)_{7}/(TA)_{5} was associated with cholelithiasis in SCA and in the control group by cons (TA)_{7}/(TA)_{8} was associated only among SCA children patients. Our results are similar with those of Chaar et al. on Guadeloupe SCA patients [7], where they demonstrated that frequency of cholelithiasis was significantly higher in both adult and children patients with (TA)_{7}/(TA)_{5} and (TA)_{7}/(TA)_{8} genotypes compared to those with other genotypes. Our results are similar to those of previous studies concerning (TA)_{7} variant which presents an excess risk for gallstone occurring in children patients with SCA and thalassemia (minor, intermedia, and β0) [4–16]. Outside of hemolytic disease, (TA)_{7} variant has been reported by many studies to be associated with both hyperbilirubinemia and cholelithiasis [25, 26, 28, 30, 31]. Herein, we demonstrated the association of the genotype (TA)_{7}/(TA)_{5} with cholelithiasis in SCA patients and in the control group. Our study is the first findings about the implication of A(TA)_{n}TAA of UGT1A1 in lithogenesis among SCA children patients in Tunisia. Our data confirmed the role of (TA)_{7} variant and highlighted the role of (TA)_{8} in early gallstones formation; association is not found in previous studies. As future directions of our research, we will focus on the Gly71Arg polymorphism in the first exon of the UGT1A1 gene reported to be associated with the same phenotypes [2, 25, 27, 32, 33]. Also we will focus on other candidate genes which can be associated with both hyperbilirubinemia and cholelithiasis in SCA such as SLCO1B1 and SLCO1A2 [34].

5. Conclusion
The novelty of this report is that it is the first time that a similar study was made on the Tunisian children sickle cell population and that the results show a clear association of (TA)_{7}/(TA)_{5} and (TA)_{7}/(TA)_{8} genotypes as well as the (TA)_{7} allele with the cholelithiasis and hyperbilirubinemia. Interestingly our findings show the association of (TA)_{8} allele with the cholelithiasis, association not described previously in other population.

Abbreviations
CI: Confidence interval
OR: Odds ratio

P: Index of significance
SCA: Sickle cell anemia
UGT1A1: Uridine diphosphoglucuronosyltransferase 1A1.
