Medicinal plants are recognized as sources of natural antioxidants that can protect from biological system oxidative stress. The present cross-sectional before/after clinical trial was carried out to investigate the antioxidant properties of the decoction of the flowers of *Echium amoenum* Fisch & C.A. Mey in humans. A group of 38 healthy subjects was invited to use the *E. amoenum* (7 mg kg⁻¹) twice daily for 14 days. Blood samples before and after entering the study were measured for lipid peroxidation level (LPO), total antioxidant capacity (TAC) and total thiol (SH) molecules. A significant reduction of blood LPO (24.65 ± 11.3 versus 19.05 ± 9.7, *P* = 0.029) was observed after 14 days of *E. amoenum* consumption. Blood TAC (1.46 ± 0.51 versus 1.70 ± 0.36, *P* = 0.018) and total thiol molecules (0.49 ± 0.11 versus 0.56 ± 0.12, *P* = 0.001) increased after 14 days of *E. amoenum* consumption. In conclusion, this antioxidative stress potential of *E. amoenum* may be due to its bioactive antioxidant components, especially rosmarinic acid and flavonoids. In recent years the importance of oxidative stress in the pathophysiology of many human disorders has been confirmed, thus use of this plant as a dietary supplement is highly recommended.

**Keywords:** antioxidant – decoction – *Echium amoenum* Fisch & C.A. Mey – human – oxidative stress

**Introduction**

Free radicals, like reactive oxygen species (ROS), nitrogen (RNS) and chlorine (RCS), are normal by-products of metabolism and they are introduced into the body from outside sources of harmful chemicals in the environment, unhealthy foods, stress, certain drugs, cigarette smoke, etc. Increasing the intake of antioxidants can neutralize free radicals and protect the body from cell damage. In the body, oxidative stress results from the imbalance between the extent of ROS formation and the antioxidant defense mechanisms. Links between oxidative stress and adverse health effects have been suggested for several groups of diseases, including cardiovascular, respiratory and neurological as well as for the general aging process. Such adverse effects are mediated by free radical damage to lipids, proteins and DNA. Protection from damage occurs through the action of multiple antioxidants, some endogenously produced and some provided through dietary intake (1–3). It is believed that medicinal plants are a potential source of antioxidants and ROS scavenger molecules (4). One of these plants is *Echium amoenum* Fisch & C.A. Mey that has been shown as a rich source of antioxidants, like rosmarinic acid (RA) and flavonoids. This plant belongs to the Boraginaceae family and is a biennial or perennial herb.
indigenous to the narrow zone of northern part of Iran and Caucasus, where it grows at highlands at the altitude ranging from 60 to 2200 m (5).

There has been an increased interest in Echium species, including E. amoenum (F.M.), because of their medicinal and nutritional properties. E. amoenum (F.M.) is one of the most important medicinal plants in Iranian traditional medicine (6). The flowers of this plant have been used as demulcent, anti-inflammatory and analgesic, anxiolytic, and sedative in folk medicine of Iran (5–7). Anxiolytic effect of the flower of this plant has been shown in two separate experimental studies in mice (8,9). In Western medicine, the flowers and the leaves of borage have been similarly used as antifebrile, antidepressant, anxiolytic, ameliorant of heart and pulmonary disturbances, poultice for inflammatory swellings, diuretic, laxative, emollient and demulcent, and recently as a possible protective factor against cancer (10–12). Extract of this plant has been shown to contain flavonoids, saponins, unsaturated terpenoids and sterols (8). Extract of Echium was effective at intraperitoneal doses of 80–125 mg kg\(^{-1}\) in animals (10) and has not been toxic in doses as high as 6 g kg\(^{-1}\) (13).

Phytochemical studies on E. amoenum revealed the presence of many chemicals such as RA, anthocyanidine, flavonoids, \(\gamma\)-linolenic acid and trace amount of alkaloids (6,14,15). The antioxidant properties of flavonoids (16,17) and RA (18–22) have been well established.

Regarding the above-mentioned information, we were interested in performing a cross-sectional before/after clinical trial study to explore antioxidant influences of E. amoenum (F.M.) in human by evaluation of blood total antioxidant capacity (TAC), lipid peroxidation (LPO) and total thiol (SH) molecules.

### Subjects and Methods

#### Study Design

A clinical trial study with a total of 38 subjects was designed. Subjects were volunteer students of Arak University of Medical Sciences, located in the south-west of Iran, who all lived in the university dormitory. Subjects were selected on a simple random basis from volunteers. The study was conducted in complete accordance with the declaration of Helsinki. All participants were provided with specific written consents obtained prior to entrance into the study. Each individual was extensively interviewed by a specialized physician who filled in a structured questionnaire specifying gender, smoking, dietary habits, sports habits and history of special disease, before obtaining blood. Then the subjects were...
administered *E. amoenum* (F.M.) flower decoction (7 mg kg\(^{-1}\)) twice daily (morning and evening) for 2 weeks. The dose was selected on the basis of a pilot study and traditional use information. A supervisor carefully checked to make sure that the volunteers were taking the decoction properly. Demographic characteristics of the subjects are presented in Table 1.

### Materials

5,5′-Dithiobis-2-nitrobenzoic acid (DTNB), Tris base, 1,1,3,3′-tetraethoxypropane (MDA) from Sigma, UK, 2-thiobarbituric acid (TBA), trichloroacetic acid (TCA), n-butanol from Merck, Germany, and 2,4,6-tripyridyl-s-triazine (TPTZ) from Fluka, Italy, were used in this study.

### Plant Material

Flowers of *E. amoenum* (F.M.) were collected from a farm at 80 km north of Ghazvin (a city in western Iran) in June 2002. A total of 450 g air-dried flowers of *E. amoenum* was used to provide the decoction.

### Plasma Preparation

Five milliliters of heparinized blood was collected from each subject at the end of the 2 week treatment, centrifuged at 1200 \(g\) for 10 min at 4°C and plasma freezes at −80°C until analysis. Blood samples were collected 12 h after the last dose of decoction was taken.

### Measurement of Plasma TAC

Antioxidant capacity of plasma was determined by measuring the ability of plasma to reduce Fe\(^{3+}\) to Fe\(^{2+}\). The complex between Fe\(^{2+}\) and TPTZ gives a blue color with absorbance at 593 nm (23).

### Measurement of Plasma Total Thiol Molecules

Total sulfhydryl content was determined in plasma by the method of Hu (24). A volume of plasma (0.20 ml) was mixed in a 10 ml test tube with 0.6 ml of Tris–EDTA buffer (Tris base 0.25 M, EDTA 20 mM, pH 8.2) followed by the addition of 40 \(\mu\)l of 10 mM of DTNB in methanol. The final volume of the reaction mixture was made up to 4.0 ml by adding 3.16 ml of methanol. The test tube was capped, and the color was developed for 15–20 min, followed by centrifugation at 3000 \(g\) for 10 min at ambient temperature. The absorbance of the supernatant was measured at 412 nm.

Measurement of LPO

LPO of plasma was determined by the reaction of TBA with MDA and other lipid peroxides. Briefly, plasma samples were mixed with TCA (20%) and the precipitate was dispersed in \(\text{H}_2\text{SO}_4\) (0.05 M). TBA (0.2% in sodium sulfate) was added and heated for 30 min in a boiling water bath. LPO adducts were extracted by n-butanol and absorbance was measured at 532 nm (25).

### Statistics

Paired \(t\)-test was used to analyze the significance of differences observed between study groups. \(F\)-test was used to determine the normal distribution of variances between groups. \(P\)-values >0.05 were considered insignificant.

### Results and Discussion

A significant decrease \((P < 0.05)\) in LPO was observed by use of *E. amoenum*. The mean ± SD before and after using were 24.65 ± 11.33 and 19.05 ± 9.7 nmol ml\(^{-1}\) (Fig. 1). After use of the decoction, the TAC level increased significantly \((P < 0.05)\). The mean ± SD values before and after were 1.46 ± 0.51 and 1.70 ± 0.36 mmol ml\(^{-1}\) (Fig. 2). A significant \((P < 0.001)\) increase in total thiol molecules was observed after administration of the decoction (0.49 ± 0.11 mmol ml\(^{-1}\) before versus 0.56 ± 0.12 mmol ml\(^{-1}\) after (Fig. 3).

The Consumption of *E. amoenum* Markedly Decreases ROS Concentrations

In this study, the influence of usage of the decoction (7 mg kg\(^{-1}\)) twice daily (morning and evening) for 2 weeks on the oxidative stress status of healthy subjects was studied. Results indicate that TAC and thiol groups increased and LPO as a marker of ROS concentration markedly decreased after consumption of *E. amoenum*. In the body, antioxidants act as free radical scavengers and thus protect cells from being exposed to free radicals and further cellular damage. This is the mechanism by which they protect the human body from several diseases attributed to the reactions of radicals. Numerous substances have been suggested to act as antioxidants in this plant. Various phenolic antioxidants such as flavonoids, RA, tannins, coumarins, xanthenes and, more recently, procyanidins have been shown to scavenge radicals in a dose-dependent manner (26,27). In addition, flavonoids and RA have been introduced as the main constituents of *E. amoenum* (F.M.) in several phytochemistry studies (6,16,17,27,28).

The antioxidant potential of flavonoids has been well established (22,23). Flavonoids can highly scavenge most types of oxidizing molecules, including singlet oxygen and various free radicals, and thus act indirectly as an efficient antioxidant (29). They can also act directly by suppressing ROS formation (30).

RA Reduced Pro-inflammatory Molecule Expression and Enhanced Antioxidative Activity

RA, the other important constituent of this plant, is an ester of caffeic acid and 3,4-dihydroxyphenylacetic acid. It is commonly found in species of the Boraginaceae and the subfamily Nepetoideae of the Lamiaceae. There are a number of reports on the antioxidative activities of RA which all confirm that RA has strong antioxidant activity even higher than vitamin E. In this regard, the reported positive effects of RA include enhancement of superoxide and hydroxyl scavenging (20), inhibition of both low-density lipoprotein (21) and oil oxidation (19), suppression of arachidonate metabolism formation (31), inhibition of hemolysis (32), and having hyaluronidase enhancement of superoxide and hydroxyl scavenging (20), E. amoenum (34). In addition, RA inhibited lung injury in mice that is regularly induced by diesel exhaust particles. RA showed this by reduction of pro-inflammatory molecule expression and enhanced antioxidative activity (34).

In conclusion, the present findings well indicate that E. amoenum (F.M.) decoction has very good potential to improve human antioxidative status and prevent normal oxidative stress that happens due to normal exposure to many causal chemicals and conditions. This potential of E. amoenum (F.M.) seems to be due to its bioactive antioxidant components, especially RA and flavonoids. In recent years the importance of oxidative stress in the pathophysiology of many human disorders has been highlighted (35–44), thus use of this plant as a dietary supplement is highly recommended (45,46). Trials to establish efficacy and optimum dosage of the present herbal product for treating human chronic diseases with pathophysiology of oxidative stress are essential.
