Moutan Cortex (MCE) has been used in traditional medicine to remove heat from the blood, promote blood circulation and alleviate blood stasis. This study was conducted to evaluate the effects of MCE on regulatory mechanisms of cytokines and nitric oxide (NO) involved in immunological activity of Raw264.7 cells. Cells were pretreated with methanolic extracts of MCE, and further cultured for an appropriate time after lipopolysaccharide (LPS) addition. During the entire experimental period, 0.1 and 0.3 mg ml\(^{-1}\) of MCE had no cytotoxicity. In these concentrations, MCE inhibited the production of NO and prostaglandin E\(_2\) (PGE\(_2\)), the expression of inducible NO synthase (iNOS), cyclooxygenase-2 (COX-2) and phosphorylated inhibitor of \(\kappa\)B (p-I\(\kappa\)B), and the activation of nuclear factor \(\kappa\)B (NF-\(\kappa\)B). MCE also reduced the concentration of tumor necrosis factor-\(\alpha\) (TNF-\(\alpha\)), interleukin-1\(\beta\) (IL-1\(\beta\)) and interleukin-6 (IL-6) in the Raw264.7 cells that were activated by LPS. These results demonstrate that MCE has anti-inflammatory effects through the inhibition of iNOS and COX-2 expression by suppressing the phosphorylation of I-\(\kappa\)B and the activation of NF-\(\kappa\)B.

Keywords: LPS – Moutan Cortex – NF-\(\kappa\)B – nitric oxide

Introduction

Moutan Cortex (MCE), the root cortex of \(Paeonia suffruticosa\) Andrews, is a traditional Korean herb with various biological activities. It has been used in oriental medicine to remove heat from the blood, promote blood circulation and remove blood stasis (1). Moutan Cortex has been shown to have antimicrobial actions against \(Escherichia coli\), typhoid, paratyphoid bacilli and \(Cholera vibrio\), and antihypertensive efficacy including analgesic, sedative and anticonvulsant effects. Moutan Cortex exerts a protective effect against acetaminophen-induced hepatotoxicity by attenuating GSH depletion, cytochrome P450 2E1 activity and hepatic DNA damage (2,3), and scavenging effects on the DPPH (1,1-diphenyl-2-picrylhydrazyl) radical, superoxide anion radical (4), hydroxy radicals (5) and intracellular ROS in oxidative condition (6).

Lipopolysaccharide (LPS)-activated macrophages have usually been used for evaluating the anti-inflammatory effects of various materials. LPS is a principle component of the outer membrane of Gram-negative bacteria, is an endotoxin that induces septic shock syndrome and stimulates the production of inflammatory mediators such as nitric oxide (NO), tumor necrosis factor-\(\alpha\) (TNF-\(\alpha\)), interleukins, prostanooids and leukotrienes (7–9). Therefore, LPS plays a key role in not only eliciting an inflammatory response but also causing septic shock during a Gram-negative bacterial infection. Inflammatory responses are advantageous for eradicating bacteria, as long as they are under control. However, when out of control, deregulated inflammation leads to the massive production of proinflammatory cytokines such as TNF-\(\alpha\), interleukin-1 (IL-1) and interleukin-6 (IL-6) by macrophages (10,11), which can cause tissue injury and multiple organ failure (12).

Recently, there have been many studies concerning natural products with anti-inflammatory activity, for example, \(Polygonum tinctorium\) (13), \(Melia azedarach\) (14), \(Cyperus rotundus\) (15,16), \(Cudrania tricuspidata\) (17), Ginsenoside Rg3 (18), sauchinone (19,20), \(curcuma\) rhizomes (21) and...
Farfarae Flos (22). Although Moutan Cortex has been used as an anti-inflammatory agent in oriental medicine, the mechanisms of anti-inflammatory activity of Moutan Cortex have not been studied scientifically. Paeonol is a major component of Moutan Cortex that may be largely responsible for the therapeutic effect of Moutan Cortex. Paeonol regulated histamine, IgE and TNF-α (23). However, it is not enough to explain the anti-inflammatory activity of paeonol and Moutan Cortex. There is no evidence to explain the mechanism on the inflammatory cytokine regulation of Moutan Cortex. Including paeonol, there are many known chemical components of Moutan Cortex such as paenoside, paeonolide, paeoniflorin, oxypaeonolniflorin, benzoylpaeoniflorin, benzoyl-ox-paeoniflorin and apiopaeonoside. Therefore, this study evaluated the effect of methanol extract of Moutan Cortex (MCE) on the regulatory mechanism of NO, cytokines and prostaglandin E₂ (PGE₂) in the LPS-activated Raw264.7 cells.

Methods

Preparation of Methanol Extract of Moutan Cortex

Moutan Cortex (300 g, Wolsung, Daegu, Korea) was extracted with 1000 ml of methanol at room temperature for 24 h. The extract was filtered through a 0.2 μm filter (Nalgene, New York, NY, USA), lyophilized and stored at −20°C until needed. The amount of the extract was estimated by dividing the dried weight of Moutan Cortex into the lyophilized MCE. The yield of MCE from Moutan Cortex was 13.2%.

Cell Culture

Raw264.7 cell, which is a murine macrophage cell line (KCLRF, Korean Cell Line Research Foundation, Seoul, Korea), was cultured in Dulbecco’s modified Eagle’s medium (DMEM, Cambrex Bio Science, MD, USA) containing 10% fetal bovine serum (FBS), 100 U ml⁻¹ penicillin and 100 μg ml⁻¹ streptomycin. For all experiments, the cells were grown to 80–90% confluence, and were subjected to no more than 20 cell passages. The cells were maintained at 37°C in a humidified atmosphere containing 5% CO₂. The Raw264.7 cells were plated at a density of 2–3 × 10⁶ per ml and preincubated at 37°C for 24 h. After serum starvation for 12 h, the cells were exposed to either LPS (1 μg ml⁻¹) or LPS + MCE for the indicated time periods (6–24 h). MCE was dissolved in a medium (EMEM, Cambrex Bio Science, MD, USA) and added to the incubation medium 1 h prior to adding the LPS.

Reagents

LPS (E. coli 026:B6) and 3-[(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazoleum (MTT) were obtained from Sigma (St Louis, MO, USA). The FBS and antibiotics were purchased from Gibco/BRL (Eggenstein, Germany). The antibodies were obtained from BD Bioscience (USA), Cayman (USA) and Zymed (USA), and the NC paper used was Schleicher & Schuell (USA). The TNF-α, IL-6 and interleukin-1β (IL-1β) ELISA kits were purchased from Pierce endogen (Rockford, IL, USA).

Assay of NO Production

The level of NO production was monitored by measuring the nitrite concentration in the cultured medium. Briefly, the samples were mixed with Griess reagent (1% sulfanilamide, 0.1% N-1-naphthylenediamine dihydrochloride and 2.5% phosphoric acid) and incubated for 10 min at room temperature. The absorbance was measured at 540 nm using a Titerpak Multiskan Automatic ELISA microplate reader (Model MCC/340, Huntsville, AL).

Cell Viability (MTT assay)

The Raw264.7 cells were plated at a density of 5 × 10⁴ cells per well in a 96-well plate to determine the cytotoxic concentrations of MCE. The cells were exposed to MCE at concentrations of 0.1 and 0.3 mg ml⁻¹ at 37°C under 5% CO₂. After incubating the cells in the presence of MCE, the viable cells were stained with MTT (0.5 mg ml⁻¹) for 4 h. The media were then removed and the formazan crystals produced in the wells were dissolved in 200 μl of dimethylsulfoxide (DMSO). The absorbance was measured at 540 nm using a Titerpak Multiskan Automatic ELISA microplate reader (Model MCC/340, Huntsville, AL). The cell viability was defined as the % of untreated control cells [i.e. viability (% control) = 100 × (absorbance of MCE-treated sample)/(absorbance of control)].

Immunoblot Analysis

The cells were lysed in the buffer containing 20 mM Tris (pH 7.5), 1% Triton X-100, 137 mM sodium chloride, 10% glycerol, 2 mM EDTA, 1 mM sodium orthovanadate, 25 mM beta-glycerophosphate, 2 mM sodium pyrophosphate, 1 mM phenylmethylsulfonylfluoride and 1 mg ml⁻¹ leupeptin. The total cell lysate was prepared by centrifuging the cells at 10,000× g for 10 min and collecting the supernatant. The expression of iNOS, cyclooxygenase-2 (COX-2) and phospholipid inhibitor of κBα (p-IκBα) was immunochemically monitored with the total lysate fraction using anti-mouse iNOS, COX-2 and p-IκBα antibodies, respectively. The bands for the iNOS, COX-2 and p-IκBα proteins were visualized using ECL western blotting detection reagents (Amersham Biosciences, NJ, USA) according to the manufacturer’s instructions.

Gel Retardation Assay

A double-stranded DNA probe for the consensus sequence of nuclear factor κB (NF-κB) (5'-AGTTGAGGGACTTTCCCAAGG-3') was used for the gel shift analyses after end labeling the probes with [γ-³²P]ATP and T₄ polynucleotide kinase. The reaction mixtures contained 2 μl of 5× binding buffer
(20% glycerol, 5 mM MgCl₂, 250 mM NaCl, 2.5 mM EDTA, 2.5 mM dithiothreitol, 0.25 mg ml⁻¹ poly dI-dC and 50 mM Tris–Cl, pH 7.5), 2 μg of the nuclear extracts and sterile water in a total volume of 10 μl. The reactions were initiated by adding 1 μl of the probe (10⁶ c.p.m.) and preincubating the resulting mixture for 10 min. Incubation was continued for 20 min at room temperature. The samples were loaded onto 4% polyacrylamide gels at 140 V. The gels were removed, fixed and dried, followed by autoradiography.

Measurement of Cytokines Production

For the cytokine immunoassays, the cells (1×10⁶ per ml) were preincubated with MCE for 1 h and further cultured for 6 or 12 h with 1 μg ml⁻¹ of LPS in 6-well plates. The supernatants were removed at the allotted times and the level of TNF-α, IL-6 and IL-1β production was quantified using an ELISA kit (Pierce endogen, Rockford, IL, USA) according to the manufacturer’s instructions. Briefly, 50 μl of biotinylated antibody reagent and the samples were added to the anti-mouse TNF-α, IL-6 and IL-1β precoated 96-well strip plates. The plates were covered and kept at room temperature for 2 h and washed three times in a prepared washing buffer. This was followed by the addition of 100 μl of Streptavidin–HRP concentrate. After 30 min incubation at room temperature, the wells were washed three times, and 100 μl of TMB substrate solution was then added and developed in the dark at room temperature for 30 min. The reaction was quenched by adding 100 μl of TMB stop solution, and the absorbance of the plates was at 450 nm to 550 nm using an automated microplate ELISA reader. A standard curve was run on each assay plate using recombinant TNF-α, IL-6 and IL-1β in serial dilutions. Each kit was specific to TNF-α, IL-6 or IL-1β and does not measure other cytokines.

Measurement of PGE₂ Production

MCE was added to the culture medium 1 h before the addition of 1 μg ml⁻¹ LPS. LPS-treated cells were further cultured with vehicle or MCE for 24 h. The cultured medium was collected and assayed with ELISA kit (RnD Systems, Minneapolis, MN, USA). Cultured medium was incubated in goat anti-mouse IgG coated plate with acetylcholinesterase linked to PGE₂ and PGE₂ monoclonal antibody for 18 h at 4°C. The plate was emptied and rinsed five times with wash buffer contained in the kit. And then, 200 μl of substrate reagent was added to each well and incubated for 1 h at 37°C. The developed plate was read at 405 nm and the PGE₂ concentration of each sample was determined according to the standard curve.

Statistical Analysis

The data were expressed as a mean ± SD of the results obtained from a number (n) of experiments. One-way analysis of variance (ANOVA) was used to assess the significant differences between the treatment groups. For each significant effect of treatment, the Newman–Keuls test was used to compare the multiple group means. A P-value <0.05 was considered significant.

Results

MCE Inhibits LPS-Activated NO, Cytokines and PGE₂ Release

The inhibition of NO production by MCE was investigated by measuring the level of NO production in Raw264.7 cells treated with 0.1 and 0.3 mg ml⁻¹ of MCE. As shown in Fig. 1, in the LPS plus MCE groups, the level of NO production decreased in a concentration and time-dependent manner compared with the LPS only group. In the 0.1 and 0.3 mg ml⁻¹ of MCE group, the level of NO was significantly inhibited at 12 h and 24 h (Fig. 1A).

Figure 1. NO release and the cytotoxicity by MCE in LPS-activated Raw264.7 cells. The NO concentration (A) in the culture medium and cytotoxicity (B) were measured over a 6–24 h period. The data represent the mean ± SD of eight separate experiments. One-way ANOVA was used to compare the multiple group means followed by Newman–Keuls test (*: significant compared with the control, **P < 0.01, #: significant compared with the LPS alone, ##P < 0.01).
Cell viability was measured at different MCE concentrations for different times using an MTT assay in order to determine if the decrease in NO production was caused by a decrease in the cell population as a result of MCE-induced cytotoxicity. The results showed that MCE concentration dose revealed no cytotoxicity over a 6 to 24 h period (Fig. 1B).

We treated LPS to Raw264.7 cells, collected media every 3 h for 24 h, detected cytokines from the collected media, and then determined appropriate time for each cytokine assay. TNF-α, IL-1β, and IL-6 were highly induced by LPS at 12, 12 and 6 h, respectively (data are not shown). TNF-α, IL-1β, and IL-6 from the culture media were analyzed at the appropriate time. As shown in Fig. 2, 0.3 mg ml⁻¹ of MCE significantly reduced the level of TNF-α (Fig. 2A), IL-1β (Fig. 2B) and IL-6 (Fig. 2C) at 12, 12 and 6 h incubation. LPS-activated PGE₂ also decreased by MCE as compared to control (Fig. 2D). PGE₂ per 1 ml medium was 6.89 pg in control and increased to 48.6 pg in LPS group. However, PGE₂ was reduced to 30.2 and 14.5 pg ml⁻¹ in 0.1 and 0.3 mg ml⁻¹ of MCE, respectively.

**Inhibitory Activities of MCE on LPS-Activated iNOS and COX-2 Expression**

The expression level of the iNOS protein in the cytosol fraction was next examined using immunoblotting analysis. The iNOS protein was strongly induced by LPS. The groups of 0.1 and 0.3 mg ml⁻¹ of MCE showed a decrease in iNOS protein expression in a concentration-dependent manner. As shown in Fig. 3, 0.3 mg ml⁻¹ of MCE with LPS strongly suppressed the induction of iNOS.

COX-2 plays a key role in the development of inflammation (24,25). MCE was further investigated to determine if it affects the COX-2 expression levels. As shown in this experiment, the

---

**Figure 2.** Inhibition of LPS-activated cytokines and PGE₂ production by MCE. Raw264.7 cells were cultured with LPS (1 μg ml⁻¹) in the presence or absence of MCE for 12 h to determine the level of TNF-α (A) and IL-1β (B). For IL-6 (C), the cells were incubated for 6 h under same conditions. For PGE₂ (D), the cells were incubated for 24 h under same conditions. The cultured medium was collected and directly assayed for cytokines and PGE₂. Data represent the mean ± SD of eight separate experiments. One-way ANOVA was used to compare the multiple group means followed by a Newman–Keuls test (*: significant as compared to control, **P < 0.01, #: significant as compared to LPS alone, *P < 0.05, ##P < 0.01).
COX-2 protein was strongly induced by LPS. 0.1 mg ml\(^{-1}\) of MCE slightly suppressed the induction of COX-2, but 0.3 mg ml\(^{-1}\) of MCE with LPS strongly suppressed the induction of COX-2 (Fig. 3).

Inhibitory Activities of MCE on I\(\kappa\)B\(\alpha\) Phosphorylation and NF-κB Activation

In order to determine if MCE can directly affect p-I\(\kappa\)B\(\alpha\) expression in macrophage cells, the level of p-I\(\kappa\)B\(\alpha\) protein expression was assessed immunochemically in Raw264.7 cells incubated with or without MCE. LPS increased the p-I\(\kappa\)B\(\alpha\) level. However, 0.1 mg ml\(^{-1}\) of MCE reduced the LPS-inducible p-I\(\kappa\)B\(\alpha\) expression level, and 0.3 mg ml\(^{-1}\) of MCE markedly reduced the protein levels of p-I\(\kappa\)B\(\alpha\) expression in a dose-dependent manner (Fig. 4A).

NF-κB is activated in cells challenged with LPS, and is involved in the transcriptional activation of the responsive genes. Gel shift analysis was carried out to determine if MCE alters the NF-κB DNA binding activity. LPS (1 \(\mu\)g ml\(^{-1}\), 1 h) increased the binding activity of the nuclear extracts to the NF-κB DNA consensus sequence. Although the treatment of macrophages with 0.1 mg ml\(^{-1}\) of MCE for 1 h prior to the addition of LPS slightly inhibited the LPS-inducible increase in the band intensity of NF-κB binding, a pretreatment with 0.3 mg ml\(^{-1}\) of MCE significantly (<50%) suppressed the band intensity that was increased by LPS (Fig. 4B).

Discussion

Inflammation is the first response of the immune system to infection or irritation. It is caused by cytokines such as TNF-α, IL-1 and IL-6 (10), and by eicosanoid such as PGE\(_2\) (26). Thus, inhibitors of these cytokines have been considered as a candidate of an anti-inflammatory drug. Moutan Cortex has been used to diminish inflammation in oriental medicine. However, few studies have been conducted to evaluate the effects of Moutan Cortex on inflammation. Herbal medicine, keishibukuryogan (Gui-Zhi-Fu-Ling-Wan) containing Moutan Cortex, was reported to decrease disease activity evaluated by levels of inflammatory cytokines (27). In this study, we show that MCE could modulate the regulatory mechanism of NO, cytokines and PGE\(_2\) in the LPS-activated Raw264.7 cells. MCE inhibited the level of NO, PGE\(_2\), TNF-α, IL-1β and IL-6, and the expression of iNOS and COX-2 activated by LPS. These inhibitory effects were mediated through the inhibition of I\(\kappa\)B\(\alpha\) phosphorylation and NF-κB activation.

NO is a free radical produced from L-arginine by nitric oxide synthases (NOSs), and an important cellular second messenger (28). The modulation of iNOS-mediated NO release is one of the major contributing factors during the inflammatory process (18). At adequate concentrations, NO can generate or modify intracellular signals, thereby affecting the function of immune cells, as well as tumor cells and resident cells of different tissues and organs. However, its uncontrolled release can cause inflammatory destruction of target tissue during an infection (29–31). Moutan Cortex has cytoprotective effects against NO-mediated neuronal cell death in cultured cerebellar granule cells (CGCs) (32). In our
study, MCE reduced the level of iNOS expression in a concentration-dependent manner. PGE2 is generated by the sequential metabolism of arachidonic acid by cyclooxygenase and is associated with inflammation (26). Cyclooxygenase exists in two isoforms; COX-1 and COX-2. COX-1 is a constitutively expressed enzyme with general housekeeping function. COX-2 is an inducible isoform of cyclooxygenase (33,34), and its most important role is in inflammation. Herb medicine containing Moutan Cortex acts as a potent inhibitor of COX-1 and COX-2 (35). Moutan Cortex also showed analgesic effect on the PGE2-induced allodynia in mice (36). We found that MCE could suppress the induction of COX-2 by PGE2, and consequently reduce the production of PGE2 in a dose-dependent manner.

NF-kB has been implicated in the expression of iNOS and COX-2 protein. Activation of the NF-kB signaling cascade results in the complete degradation of I-kB and phosphorylation and ubiquitination. Paeonol showed regulatory effects on inflammatory cytokines-related anaphylactic reaction (37), and cerebral disorder (38). Recently, paeonol was reported to reduce TNF-α-stimulated iNOS protein and mRNA expression via inhibiting NF-kB activation (39). In this study, MCE inhibited the phosphorylation of I-kBα and LPS-inducible increase in the band intensity of NF-kB binding. Thus, it seems that anti-inflammatory effect of MCE is partly responsible for paeonol. To evaluate the anti-inflammatory activity of paeonol in LPS-induced macrophage, studies on the effects of paeonol on the mechanism of LPS-induced NO, cytokines and PGE2 are needed.

In conclusion, we determined that the MCE can have anti-inflammatory activity by suppressing the phosphorylation of I-kBα and the activation of NF-kB, and by inhibiting the expression of iNOS and COX-2 in LPS-activated Raw264.7 cells.
