Tropidurus hispidus and Tropidurus semitaeniatus are two lizard species utilized in traditional medicine in Northeast Brazil. Their medicinal use includes diseases related with bacterial infections such as tonsillitis and pharyngitis. They are used in the form of teas (decoctions) for the treatment of illnesses. In this work, we evaluated the antimicrobial activity of the decoctions of T. hispidus (DTH) and T. semitaeniatus (DTS) against bacterial strains, namely, standard and multiresistant Escherichia coli, Staphylococcus aureus, and Pseudomonas aureuginosa, alone and in combination with aminoglycoside antibiotics. The decoctions were prepared using the whole body of the dried lizards, and the filtrate was frozen and lyophilized. When tested alone, the samples did not demonstrate any substantial inhibition of bacterial growth. However, in combination with antibiotics as aminoglycosides, decoctions reduced the minimal inhibitory concentration (MIC) of the assayed antibiotics against multiresistant strains of S. aureus and P. aureuginosa. Chemical prospecting tests revealed the presence of alkaloids in DTS. This is the first study evaluating the medicinal efficacy of T. hispidus and T. semitaeniatus and contributes to the list of new sources of medicines from natural products of animal origin.

1. Introduction

Natural substances from animals, plants, and minerals have provided a continuous source of medications [1]. In Brazil, as in other countries, animals and plants have been widely utilized since antiquity by the traditional medicine [2, 3], and according to Alves and Rosa [4], they have played a significant role in the healing arts up to nowadays.

Despite their prevalence in the practice of traditional medicine throughout the world, the medicinal use of animals have often been neglected in research, compared to medicinal plants [5]. According to Alves et al. [6], emphasis has been placed for the most part on plant-based medications more than on those from animal origin. Besides, plants are easier to collect, store, and sell. However, recent publications have demonstrated the importance of zootherapy in different sociocultural environments worldwide, and examples of the use of remedies derived from animals can currently be found in many urban and semiurban localities, particularly in developing countries [2, 3, 7, 8].

Reptiles are among the species most utilized in popular medicine, and their role in practices and beliefs related to the treatment and/or prevention of diseases has been reported by different traditional communities worldwide [4, 7–11].
Despite the extensive use of reptiles for medicinal purposes, there is a general lack of detailed information about the exploitation of these animals and their impact on the species involved [11].

Among the species utilized in traditional medicine in Brazil, we can cite *Tropidurus hispidus* and *T. semitaeniatus*. *Tropidurus semitaeniatus* (Spix, 1825) is endemic to the “Caatinga” biome. Popularly known as the “outcrop lizard,” it is a small lizard with a diurnal habit. It is found on broad rocky surfaces (outcrops), and with a dorsoventral flattened body, specialized at getting into small cracks in the rocks, where it is protected and probably remains during the warmest hours of the day [12]. *T. semitaeniatus* is a carnivorous animal, with a sit-and-wait feed strategy, consuming a large variety of preys, mainly ants [13]. In popular medicine, *T. semitaeniatus* is indicated for the treatment of measles, asthma, alcoholism, dermatomycosis, and chickenpox [6].

*Tropidurus hispidus* (Spix, 1825), also known as the “lava lizard” or “catenga,” inhabits the Brazilian Northeastern region [14, 15]. It is found in diverse habitats, mainly on tree trunks, rocks, and walls [14, 15] and lives mainly in open areas. This is a diurnal and territorial lizard with a sedentary-opportunistic feed strategy [13, 15–18]. It feeds mainly on arthropods, some plants, flowers, and small vertebrates [14, 19]. According to Barbosa [20], *T. hispidus* is used in the treatment of chickenpox in a community in Paraiba State. Alves and Rosa [3] noted in their studies the popular use of this species in the treatment of sore throat, tonsillitis, and pharyngitis.

According to Freire [21] and Marques [22], the utilization of these lizards in traditional medicine is also associated with the treatment of inflammation, dermatitis, venereal diseases, and snake bites, being consumed in the form of a decoction, and because of the small size of the specimens, it is used whole in the preparation of a tea. Alves et al. [6] also described other forms of use for these species in which a tea (decoction) is included, besides the ingestion of a broth of cooked meat and the application of the live animal on the affected area. Many of these diseases such as inflammation and dermatitis can be associated with pathogenic microorganisms, including bacteria and fungi, which suggest a possible antimicrobial potential for these species.

Traditional medicine, in general, represents a field in which there is still little research in terms of evaluation of therapeutic or clinical potential [23], and few studies have been done until now to demonstrate the clinical efficacy of animal products for medicinal purposes [24]. Therefore, the aim of this work was to determine the antimicrobial activity of decoctions prepared with the lizards *T. hispidus* and *T. semitaeniatus*, tested alone and in combination with antibiotics.

### 2. Material and Methods

#### 2.1. Zoological Material. The animals were collected in the municipality of Crato (7°14′03″S × 39°24′34″W), Ceará, Brazil in April 2010. They were caught manually and with air pistols by rummaging through habitats where these animals can be found (Permission for collection: 154/2007 no. 23544-1 process no. 17842812). Once the lizards were collected and sacrificed, their skins were removed and dried in a drying oven to prepare extracts. Control specimens were fixed in 70% alcohol and deposited in the zoology collection of the Universidade Regional do Cariri/LAZ-URCA (Table 1).

#### 2.2. Preparation of Decoctions of *T. hispidus* (DTH) and *T. semitaeniatus* (DTS). The decoctions of *T. hispidus* and *T. semitaeniatus* were prepared by submersing the whole lizards, already oven-dried, in boiling distilled water for 2 h. Afterward, the decoction was filtered, frozen, and later lyophilized. A concentrated form was used in the antimicrobial assays. The yields for the decoctions are shown in Table 2. The decoctions were then stored in a freezer for future analyses.

#### 2.3. Strains. The experiments were carried out using the following bacteria: clinical isolates of *Escherichia coli* (EC27), *Staphylococcus aureus* 358 (SA358), and *Pseudomonas aeruginosa* PA RB1 and the standard strains *E. coli* ATCC 10536, *S. aureus* ATCC 25923, and *P. aeruginosa* ATCC

DTH: decoction of *Tropidurus hispidus*; DTS: decoction of *Tropidurus semitaeniatus*. 
The decoctions of the lizards *T. hispidus* and *T. semitaeniatus* did not show a clinically relevant antibacterial activity, presenting a MIC ≥1024 µg/mL against all bacterial strains tested, suggesting that these lizards are ineffective in traditional medicine against bacterial infections. DTH and DTS were tested for possible antibacterial activity when combined with commonly used antibiotics. No effect of any decoction was observed against the multiresistant strain of *E. coli*-EC27. Against the strain SA358, DTS combined with a kanamycin and amikacin significantly reduced the MIC of these antibiotics as observed in Table 4. DTH also enhanced the action of the kanamycin against the same bacterial strain. Against the multiresistant clinical isolate and *Pseudomonas aureuginosa* RB1, both DTH and DTS showed synergism with the aminoglycosides neomycin and gentamicin (Table 4). The chemical prospecting tests demonstrated the presence of alkaloids in the decoction of *T. semitaeniatus*, but not in the case of *T. hispidus*, as seen in Table 3.

### 4. Discussion

The present study demonstrated that decoctions of *T. hispidus* and *T. semitaeniatus* did not present clinically relevant antibacterial activity, with MIC of ≥1024 µg/mL against all the strains used. Similar results were obtained in a study by Ferreira et al. [28], demonstrating the lack of *in vitro* antimicrobial activity of body fat from *Tupinambis merianae*, which is used in popular medicine against bacterial infections caused by *E. coli* and *S. aureus*, besides, several proteins and peptides from animals present antibacterial activity [29].

On the other hand, a synergistic effect was observed between the extracts with aminoglycosides, reducing the MIC of the antibiotics was also observed in other studies with natural products isolated from animals and plants [30–32]. Therefore, there is a need to understand how these substances act in order to increase the activity of conventional antibiotics, since a substantial decrease in the concentration of aminoglycosides would be a promising improvement in the chemotherapy of infections. According to Matias et al. [33], several components of the extracts can act as cell permeabilizers, increasing the cellular uptake of antibiotics [34]. Interference with bacterial enzyme systems can also be a potential mechanism of action [35]. These mechanisms of action can be involved in the combination of an antibiotic with a natural product at a subinhibitory concentration [36, 37].

The presence of alkaloids in the decoction of *T. semitaeniatus* used in these antimicrobial assays can be a strong indication that these substances present the antibiotic-modifying activity, since these extracts potentiated the antibiotic action (Table 4). Studies have demonstrated different pharmacological activities of alkaloids [38, 39]. In the case of DTH, which does not contain alkaloids but still showed synergism of specific reagents. The results obtained are presented in Table 3.

### 3. Results

The decoctions of the lizards *T. hispidus* and *T. semitaeniatus* did not show a clinically relevant antibacterial activity, presenting a MIC ≥1024 µg/mL against all bacterial strains tested, suggesting that these lizards are ineffective in traditional medicine against bacterial infections. DTH and DTS were tested for possible antibacterial activity when combined with commonly used antibiotics. No effect of any decoction was observed against the multiresistant strain of *E. coli*-EC27. Against the strain SA358, DTS combined with a kanamycin and amikacin significantly reduced the MIC of these antibiotics as observed in Table 4. DTH also enhanced the action of the kanamycin against the same bacterial strain. Against the multiresistant clinical isolate and *Pseudomonas aureuginosa* RB1, both DTH and DTS showed synergism with the aminoglycosides neomycin and gentamicin (Table 4). The chemical prospecting tests demonstrated the presence of alkaloids in the decoction of *T. semitaeniatus*, but not in the case of *T. hispidus*, as seen in Table 3.
with particular aminoglycosides, other possible bioactive substances not detected may be responsible for its synergistic effect, necessitating further studies to identify these natural products.

It is important to note that the use of natural products combined with conventional drugs has been previously described. Calvet-Mir et al. [40] reported the use of traditional medicine products in combination with Western medicine for the treatment of diarrhea, vomiting, and stomach ache. Vandebroek et al. [41] reported on the use of natural products and commercial medications together for the treatment of diseases of the respiratory and digestive tracts. According to Ferreira et al. [42], studies of substances from reptiles must be stimulated to determine their pharmacological activities. Ciscotto et al. [43] described the antibacterial and antiparasitic activities of L-amino acid from reptiles must be stimulated to determine their pharmacological proprieties. Liu et al. [45] demonstrated the antitumor effect of extracts of the lizard Bothrops jararaca (Wied, 1924) venom. Products from other species of reptiles were also studied in attempt to elucidate their pharmacological properties. Morais et al. [44] reported the anticoagulant activity of antithrombin factor from Bothrops jararaca (Wied, 1924) venom. Products from other species of reptiles were also studied in attempt to elucidate their pharmacological properties. Liu et al. [45] demonstrated the antitumor effect of extracts of the lizard Gecko japonicas (Schlegel, 1836), which is widely utilized in Chinese traditional medicine. The lysozymes of the turtles Trionyx sinensis (Wiegmann, 1835), Amyda cartilaginea (Boddart, 1770), and Chelonia mydas (Linnaeus, 1758) demonstrated a strong antibacterial activity [46].

5. Conclusion

The decoctions of *T. hispidus* and *T. semitaeniatus*, alone, did not show antimicrobial activity, suggesting the ineffectiveness of products derived from these animals for the treatment of bacterial infectious diseases in traditional medicine. However, the decoctions were found to be effective when combined with aminoglycoside, demonstrating a pharmacological potential to enhance the antibiotic activity. Further studies with natural products of animal origin are needed since this field still remains few explored compared to phytotherapeutic substances, and the medicinal potential of products derived from animals can lead to notable advances in conventional medicine, as well as to the development of management techniques in the conservation of species with potential medicinal use.
