The protective effect of electroacupuncture (EA) at Zusanli points (ST36) on myocardial injury in a model of sepsis was observed. Forty-eight male Sprague-Dawley rats were subjected to sepsis by cecal ligation and puncture (CLP) and randomly divided into 4 groups (n=12; A: sepsis + EA; B: sepsis + sham acupuncture; C: sepsis + vagotomy; D: sepsis + vagotomy + EA). Bilateral points were stimulated (2mA, 2-100 Hz) for 1 hour. Abdominal vagotomy was performed in groups C and D. At 6h after CLP, the plasma activity of creatine kinase-MB (CK-MB) was determined. A part of cardiac muscle was harvested for evaluating levels of tumor necrosis factor (TNF- α), nitric oxide (NO), myeloperoxidase (MPO), and the rate of water content. The activities of CK-MB, TNF- α , NO, and MPO and the rate of water content in group A were significantly lower than those of the other groups 6h after CLP. EA after vagotomy showed less anti-inflammatory and protective effects. The results indicated that EA obviously reduced the increased levels of the proinflammatory factors at 6h after CLP, and vagotomy could weaken or eliminate the effects of EA. Cholinergic anti-inflammatory pathway is one of the main mechanisms of cardioprotective effect of EA.

1. Introduction

Serious infection, caused by trauma and major surgery, can lead to sepsis, septic shock, and multiple organ dysfunction syndromes (MODS) [1]. The heart is vulnerable in the process of sepsis, especially ischemia-reperfusion injury caused by tissue ischemia or inflammatory overstimulating [2]. Therefore, suppressing proinflammation and reducing tissue edema play important roles in the prevention and treatment of sepsis.

Acupuncture therapy has been used for thousand years in China, and two-way regulation of nerve-endocrine-immune system. Zusanli point (ST36) can promote the intestinal function and improve immunity [3]. In addition, the modern research has shown that acupuncture at Zusanli can protect organ function effectively from endotoxemia or postoperative

abdominal adhesion in rats by inhibiting inflammation factor levels [4–7].

The objective of this paper was to observe effects of electroacupuncture (EA) at Zusanli on myocardial injury in septic rats and to study the anti-inflammatory mechanism of Zusanli.

2. Materials and Methods

2.1. Experimental Animals and Grouping. Forty-eight male Sprague-Dawley (SD) rats, weighing 220 ± 20 g, were obtained from the Animal Center of Military Medical Sciences [Certificate number: SXCL-(Army-2010-006)]. The animals were housed at a constant temperature of $24 \pm 2^\circ\text{C}$ and humidity of $50 \pm 5\%$ for one week. They received no food in the 12 hours before the experiment, but had free access to water.

TABLE 1: Comparison of plasma CK-MB at 6 hours after CLP [$(\bar{x} \pm s)$, U/L].

Groups	Rats	CK-MB	Compared with group A <i>P</i> -value	Compared with group C <i>P</i> -value
A	12	3020±190	-	0.0001
B	12	3850±153	0.0001	0.0057
C	12	4106±246	0.0001	-
D	12	4090±257	0.0001	0.8776

The SD rats were randomly divided into 4 groups ($n = 12$): group A (sepsis + EA at ST36), group B (sepsis + sham acupoint), group C (sepsis + vagotomy), and group D (sepsis + vagotomy + EA at ST36).

2.2. Experimental Methods

(1) *Model Making.* The cecal ligation and puncture (CLP) model was performed according to Chaudry's method [8]. The rats came to be operated after successful intramuscular anesthesia using Ketamine and Sumianxin (2:1 preparation, 0.4 ml/kg). During the operation, the rat's abdominal skin was prepared and cut open 2 centimeters along the midline. The cecum was carefully pulled out and punctured 3 times with NO.16 needle and its root ligated, which caused fistula intestine. To prevent the punctured pinhole from closing, one rubber stripe (2 cm× 2 mm) was fixed in it to drainage. The cecum was inserted back into the abdomen, which was closed then with NO. 0 silk. The rats were given subcutaneous injection of physiological saline (50 mL/kg) for antishock and had free access to water after surgery.

(2) *Processing Methods.* All rats in this experiment were performed sepsis by CLP. Animals of groups A, B, and D were fixed with a bag (limbs exposed through four holes) and acupunctured when they were awake about 40 minutes after surgery. Zusanli point (ST36) is outside of the knee, about 5 mm below the fibular head [3]. The nonacupoint locates below the outer of ST36 about 5mm. The two needles were connected with two electrode coils, and the acupoint was stimulated continuously (2 mA, 2-100Hz) for 1 hour with a special device (HANS, LH202H, Beijing, China). The nonacupoint was stimulated using the same electrode, parameters of intensity, frequency, and time (2 mA, 2-100Hz, 1h). In groups C and D, abdominal vagotomy [9] was operated before CLP.

The rat's abdominal skin was cut open 2 centimeters along the midline after successful intramuscular anesthesia. When the stomach was gently pulled down and twisted, the vagus nerve branches of the esophagus were exposed. After that, the branches were bluntly separated, which fixed and transected by a nylon cord. All rats had free access to water and were sacrificed at 6 hours after surgery.

2.3. Observations and Detection Methods

2.3.1. *Creatine Kinase-MB (CK-MB) Content.* Six hours after CLP, all rats were hoccussed with Ketamine and Sumianxin

(2:1 preparation, 0.5 ml/kg); then abdominal arterial blood was extracted 2ml, and the CK-MB content of which was detected by automatic analyzer.

2.3.2. *Content of Tumor Necrosis Factor (TNF- α), Nitric Oxide (NO), and Myeloperoxidase (MPO).* Animals were sacrificed by draining abdominal aortic blood. A part of cardiac muscle was clipped and packed in liquid nitrogen cryopreservation. 100 mg liver and 9 ml saline were added to prepare a 10 % homogenate. Then it was centrifuged for 10–30 minutes with a speed of 1000 and 3000 rev/min, respectively (with the speed depending on the measurement targets). The supernatant after centrifuging was cryopreserved (-80°C) and prepared to be detected.

(1) *TNF- α Content.* A rat TNF- α ELISA test kit (Dialclone Company) was used (sensitivity 20 pg/ml, detection range 20-1000 pg/ml). In strict accordance with the manual steps, the instrument automatically calculated a standard curve regression equation: $y = 0.0173 + 0.0003x$, $r = 0.9942$. The optical density of the sample was put into a standard curve and multiplied by the appropriate dilution factor to calculate the sample's TNF- α content, with a unit of pg/ml.

(2) *NO and MPO Content.* An NO or MPO kit (Nanjing Jiancheng Bioengineering Institute) was used in strict accordance with the instructions. The result of NO was expressed in $\mu\text{mol/gprot}$ and MPO in U/gprot.

2.3.3. *Moisture Rate of Cardiac Tissue.* After animals were sacrificed, a part of cardiac tissue was clipped, weighed, and then put into the oven (90°C) to bake for 72 hours. The drying tissue was also weighed.

2.4. *Statistical Analysis.* ANOVA statistical analysis software was used to process the data. Differences between groups were compared (indicated with $\bar{x} \pm s$). $P < 0.05$ was considered statistically significant. The original data can be found in the Department of Rehabilitation of the 309th Hospital of People's Liberation Army in Beijing.

3. Results

3.1. *Plasma CK-MB Content.* Six hours after CLP, the CK-MB content of all rats was increased in different degrees; that of group B decreased compared to the other groups ($P < 0.01$). There was no significant difference between group C and group D ($P > 0.05$) (see Table 1).

TABLE 2: Comparison of TNF- α content in cardiac tissue at 6 hours after CLP [$(\bar{x} \pm s)$, pg/ml].

Groups	Rats	TNF- α	Compared with group A <i>P</i> -value	Compared with group C <i>P</i> -value
A	12	284.22 $\pm$ 97.87	-	0.0001
B	12	444.23 $\pm$ 111.20	0.0011	0.0136
C	12	572.45 $\pm$ 122.80	0.0001	-
D	12	570.68 $\pm$ 120.57	0.0001	0.9719

TABLE 3: Comparison of NO content in cardiac tissue at 6 hours after CLP [$(\bar{x} \pm s)$, pg/ml].

Groups	Rats	NO	Compared with group A <i>P</i> -value	Compared with group C <i>P</i> -value
A	12	2.09 $\pm$ 0.20	-	0.0001
B	12	2.50 $\pm$ 0.16	0.0003	0.0038
C	12	2.92 $\pm$ 0.42	0.0001	-
D	12	2.84 $\pm$ 0.25	0.0001	0.5765

3.2. Content of TNF- α , NO, and MPO and Moisture Rate in Cardiac Tissue. At 6 hours after CLP, the content of TNF- α , NO, and MPO and moisture rate in cardiac tissue of all groups showed a significant increase; those of group A were significantly lower than those in the other groups ($P < 0.01$ or $P < 0.05$). The above observed index showed no significant difference between groups C and D ($P > 0.05$) (see Tables 2, 3, 4, and 5).

4. Discussion

Sepsis, a systemic inflammatory response syndrome caused by infection, can lead to septic shock and multiple organ dysfunction syndrome (MODS). The heart is one of vulnerable organs in sepsis. Clinical studies confirmed that the organic heart injury had been induced in early onset of sepsis, accompanied by hypotension, cardiac failure, and arrhythmia [10].

TNF- α is the initial secretion proinflammatory cytokines when body suffers from adverse stimuli, which can damage organs directly or by other ways [11]. Some researchers found that the TNF- α level significantly increased in patients with sepsis caused by severe burns and was positively correlated with serum myocardial enzymes [12]. When sepsis or MODS occur, NO is out of control and plays an important role in systemic infection and excessive pathophysiology of inflammatory response. It can aggravate organ damage of sepsis. NO is the substrate for MPO. The removal of NO by MPO can lower NO bioavailability and inhibit nitric oxide synthase (NOS) activity. In the previous series of studies, we found that the content of TNF- α , NO, NOS, and other inflammatory factors of liver or intestine tissue was significantly increased in sepsis and abdominal adhesion rats [13–16]. These abnormal elevated inflammatory factors lead to organ dysfunction [17].

Zusanli (ST36) is the confluent acupoint of Zu Yang Ming meridians, which can promote gastrointestinal motility and improve the blood flow, immunity, and other effects. In addition, modern research results show that acupuncture

at Zusanli plays important anti-inflammatory roles, which can reduce inflammatory factor levels abnormally elevated in blood plasma or tissue of sepsis, abdominal adhesion, endotoxemia, and scald rats and protect organ function [6, 9, 18–20].

In this study, the authors observed that 6 hours after CLP, the heart of animals had adverse plasma myocardial enzyme level and ischemia-reperfusion injury. The CK-MB content, tissue moisture rate, and the levels of TNF- α , NO, and MPO were significantly increased. Compared to other groups, those of group A (EA at Zusanli) showed lower levels, which indicates that acupuncture at Zusanli had a protective effect on the myocardial injury of sepsis by inhibiting elevated levels of inflammatory cytokines.

The cholinergic anti-inflammatory pathway is to regulate against systemic inflammation, which goes through cholinergic nerve and its transmitters [21]. Direct electrical stimulation of cholinergic nerves (efferent vagus nerve) can inhibit the synthesis of TNF- α [21]. Hu et al. observed the effect of e vagus nerve electrical stimulation on acute lung injury and cardiac inflammation in endotoxemia rats. The results showed that vagus nerve stimulation could significantly reduce TNF- α and MPO activity in cardiopulmonary tissues and pathological damage [22, 23]. In the abdominal adhesion experiment, the authors found after cutting off the vagus nerve that the level of proinflammatory factors was increased. Even with stimulation of acupuncture Zusanli, it showed less decline [4, 5, 13, 19, 24]. The integrity of vagus nerve plays an important role in anti-inflammatory and organ protection.

In this study, the authors also found that when the bilateral ventral vagus nerve is cut off, acupuncture at Zusanli had less efficiency in reducing the inflammation level of sepsis rats and even more aggravation. The level of proinflammatory factors is balanced by sympathetic adrenergic nerve and parasympathetic cholinergic nerve. When the parasympathetic cholinergic nerve is blocked, the effect of sympathetic adrenergic nerve can be activated, leading to elevated level of proinflammatory cytokine.

TABLE 4: Comparison of MPO content in cardiac tissue at 6 hours after CLP [$(\bar{x} \pm s)$, U/gprot].

Groups	Rats	MPO	Compared with group A <i>P</i> -value	Compared with group C <i>P</i> -value
A	12	1.56±0.18	-	0.0001
B	12	1.80±0.24	0.0111	0.0004
C	12	2.19±0.22	0.0001	-
D	12	2.07±0.16	0.0001	0.1407

TABLE 5: Comparison of moisture rate in cardiac tissue at 6 hours after CLP [$(\bar{x} \pm s)$, %].

Groups	Rats	Moisture rate	Compared with group A <i>P</i> -value	Compared with group C <i>P</i> -value
A	12	66.2±1.9	-	0.0001
B	12	71.6±3.6	0.0001	0.0164
C	12	76.1±4.8	0.0001	-
D	12	76.4±4.4	0.0001	0.8747

5. Conclusion

EA at Zusanli had a positive role in myocardial injury of sepsis rats by reducing the high TNF- α , MPO, and NO content, lowering plasma activity of CK-MB and moisture content. The authors suggest that the anti-inflammatory and myocardial protective effects of EA at Zusanli in sepsis be related to the activation of cholinergic anti-inflammatory pathway.
